In general, where the solution of shaft frequency only is desired, the writer finds the author's method very satisfactory. If, however, a very complete analysis is needed, including calculation of amplitudes and stresses for both synchronous and forced vibration, the uniform shaft system originated by Professor Lewis with the tabular solutions given by Mr. Porter in previous papers is found very satisfactory.

Mr. Porter's paper is a notable contribution to the art of solving torsional vibration problems, and the rapid method he now presents will be welcomed by all engineers confronted with this problem.

GEORGE DASHEFSKY.[16] The author is to be complimented for his past contributions to the technique of calculations pertaining to torsional vibration, as well as for his present valuable contribution. The paper offers several labor-saving and time-saving devices for calculating the natural frequency of complex shafting systems.

In general, a complete analysis of torsional vibration characteristics of an installation may be classified into the following elements:

(1) Calculation of natural frequencies and location of critical speeds

(2) Amplitude of vibration at critical speeds

(3) Vibration stresses occurring in shafting when in a critical speed

(4) Calculation of forced vibration in proximity to the critical speeds; namely, the resonance curves for amplitude and stress.

In each of the elements listed, the frequency solution is usually directly or incidentally involved. The particular system of calculation used will depend upon the idiosyncrasies of the particular calculator. In any case the availability of another method permits an excellent check of a calculation by comparison of results obtained by two systems.

Where a family of curves is required, to show the influence upon the location of critical speeds of various connecting shaft sizes, and the moments of inertia of the driven masses such as flywheels, generators, propellers, etc., much time and labor are involved. Any device for conserving these becomes very important. The present paper in this respect is invaluable and should be of great utility.

Of the various classifications of installations shown in the paper, most cases met in conventional shaft line-ups may be thrown into the forms shown in form 2 of Fig. 4, or the forms shown in Figs. 5 and 6. The adaptation of the system to one of these forms and use of the tables may introduce some error of approximation in the calculated frequency due to interpolation of trial values of n. Usually such slight departure from the actual frequency is in itself unimportant, with respect to stating the location of critical speeds and ranges of speeds to be prohibited to operation. However, as stated at the outset, the determination of the amplitudes of vibration and of the vibration stresses and moments are dependent upon the frequency solution. It is in this respect that the writer's experience has shown that whatever system of calculation is used, whether the concentrated-mass system, the uniform-shaft system, or crosses between them, critical values of n may be encountered, and it becomes essential that the system of equations be quite closely satisfied by the value of frequency considered to applying to the "mathematical" installation.

Referring to Equations [17], [18], and [19] of the paper, it will be observed that the amplitude of vibration and vibratory twisting moments and stresses at any points in a step with mass involves a step constant α. This constant is determined by assuming unit amplitude at the beginning of the line-up and solving for the α value for the first step, and computing in turn the α values for succeeding steps, from the following relation:

$$\alpha_{k+1} = \alpha_k \frac{\cos(\phi_k n + \gamma_k)}{\cos \gamma_{k+1}}$$

This equation follows from the relations given in Equation [18] of the paper. It often happens that values of $\phi_k n + \gamma_k$ and γ_{k+1} are close to 90 deg. or 270 deg. Even small error in the assumed value of n with respect to the value of n which satisfies the system of equations in such case may result in very considerable errors in the calculation of α. Consequently, in such cases similar error results in the calculated vibration moments and stresses. Where only a frequency solution is being sought, it is not necessary to determine n with the finesse implied, and the interpolated values are usually of sufficient accuracy.

The frequency solutions devised by the author quite thoroughly systematize the frequency calculations. The tabulated values for reduction of masses and for the direct solution of some of the simpler line-ups are indeed valuable contributions to the art.

E. A. TULUS.[17] The author has contributed another very interesting paper on the important problem of Diesel-engine vibration. The proposed method for calculating natural frequencies uses a slightly different scheme than the one the writer works with now, but it gives a speedy, accurate solution through the use of standard forms and tables. In an engine with only a few cylinders the accuracy of the proposed method will not be nearly as good as the Holzer method and it is questionable whether it will be much more rapid. For standard work the Holzer method is more routine since an addition of masses simply

[16] Assistant Mechanical Engineer, Navy Yard, New York, N. Y.

[17] Research Engineer, Power Engineering Department, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

means a longer procedure. However, the theory is no more complicated and the results are very accurate. These factors in some cases may overweigh the advantage of simplicity in favor of Mr. Porter's proposed method.

To the writer's mind, the most important point in a torsional-vibration calculation for a Diesel-engine unit is the evaluation of the elastic constants of the shaft. It has been the writer's experience that a marked change in the inertia constants for the system will usually result in only a slight change in the calculated critical frequency. On the other hand, a slight change in the shaft flexibility, especially if it occurs in the nodal section,

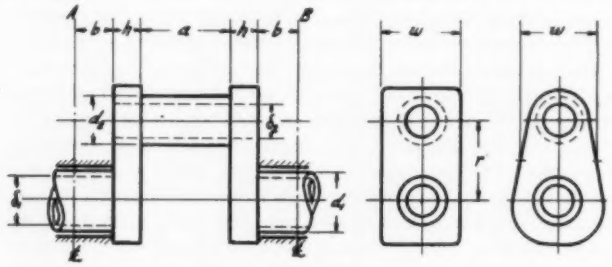

FIG. 20

will produce a large change in the natural frequency and will at times bring the unit within the dangerous range. For this reason the data presented by the author in regard to shrink fits and couplings are very important. In addition, to the valuable instructions the author has presented for calculating shrunk couplings, it would be very interesting to know if he has any data on the twist of shafts in pressed or shrunk fits and to know how this flexibility varies as a function of the length and the pressure of the fit. In short shafts this is very important because the relative value of the shrunk portion is quite large in respect to the rest of the shaft. In selecting the coupling the designer should keep in mind the application in which a Diesel drive will be used. Some of the flexible couplings have rigidity constants which vary with the load. An application of such a coupling to a constant-speed but variable-load installation, for instance, a dredge, results in unnecessary complications. Such an application would mean that the characteristics of the unit would be similar to the variable-speed unit, and hence the designer would have to consider the whole range of criticals instead of only one of them. Where the installation of the flexible coupling is necessary for some other reason, the designer should select one that has a constant rigidity coefficient or one that has very good damping properties.

Another phase of the problem of calculating rigidity constants that is important is the evaluation of the rigidity of the crankshaft. A bibliography on this subject is given at the end of this discussion.

Of the six formulas mentioned, the Geiger equation requires experimental constants and hence cannot be used directly in predetermining the crankshaft flexibility. A tabulation of all the available data and the results that have been published indicate that Carter's formula will give the most accurate results. One does not need experimental data to apply Carter's formula, and in addition the computations are relatively simple. The rigidity constant as expressed by Carter's formula is $K = \frac{G \times J}{L}$ in.-lb. per radian. G is the value of shear modulus and may be taken as 11.8×10^6 lb. per sq. in., J is the polar moment of inertia of the cross-section of the shaft and is expressed as:

$$J = \frac{\pi}{32}(d_1^4 - \delta_1^4)\text{in.}^4$$

L is the equivalent length from A to B (see Fig. 1) in terms of the journal shaft and may be found by:

$$L = (2b + 0.8h) + \frac{3}{4}a\left(\frac{d_1^4 - \delta_1^4}{d_2^4 - \delta_2^4}\right) + \frac{3}{2}r\left(\frac{d_1^4 - \delta_1^4}{h\omega^3}\right)$$

This same compilation of the crankshaft formulas shows that Constant's method usually gives closer results than Carter's. This is not surprising when one considers that Constant considers irregularities in the crank webs, whereas Carter neglects them. Nevertheless the writer prefers to use Carter's formula, because it is much simpler and gives nearly as good results.

After the calculations are completed, the designer must decide how far the operating speed must be kept from any one of the major orders of the critical. Of course, this decision will be influenced to a large extent by the type of installation. For instance, in Diesel-driven dredges there is quite a large amount damping present due to the pump impeller running under water. In such a case the limit of the difference between any one important major and the running speed may be lowered, and still the installation may be considered as safe from torsional vibrations. As another example one may mention the Diesel drive in railway service. With the present design of high-speed multiple-cylinder Diesels, the range of critical speeds is such that the actual operating range will overlap these speeds and the units have to be designed to meet this condition. Usually,

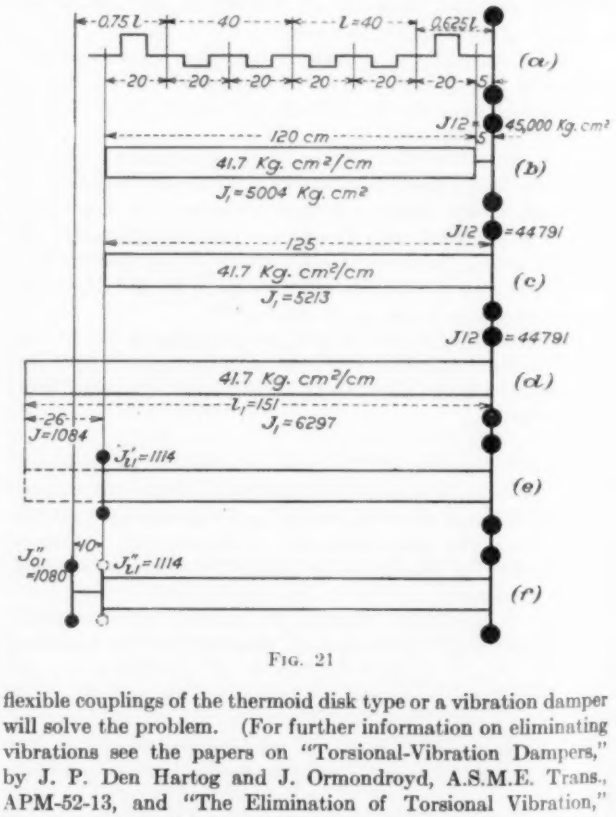

FIG. 21

flexible couplings of the thermoid disk type or a vibration damper will solve the problem. (For further information on eliminating vibrations see the papers on "Torsional-Vibration Dampers," by J. P. Den Hartog and J. Ormondroyd, A.S.M.E. Trans., APM-52-13, and "The Elimination of Torsional Vibration," by George J. Dashefsky, A.S.M.E. Trans., Penn State meeting, June, 1930.) Finally, consider a Diesel generator power installation. For this service the unit will operate at a constant speed and will probably be designed in such a way that the system will not be able to absorb the energy due to vibration by damping. In such a case the limit should be higher than in the two mentioned cases. It would be very interesting to hear of the experience of the author in similar installations. The

writer's experience is such that the difference between a major order and the running speed of a Diesel unit is varied to suit the conditions of operation, but in no case in constant-speed installations is this difference allowed to be less than 10 per cent of the operating speed.

H. Schreck.[18] The paper is of great value and will be appreciated by all engineers who have to do with the calculation of critical speed. The methods most used today are those developed by Holzer and Dr.-Ing. Wydler, both of which require a long cut-and-try method and the use of formulas of quite considerable length.

In order to try out the simple method suggested by Porter, the writer worked out an actual example presented by Dr.-Ing. Schlaefke in the *Journal* of the Verein Deutscher Ingenieure of October 18, 1930. The article points out the difference between the calculated critical speed and the actual one as determined on this engine. The calculation had not taken into account the effect of the drive off the shaft for the camshaft, and the author in his paper determined how much mass must be acting at this gear to cause a difference in the first frequency of 11,600 per min. calculated against 9700 per min. measured on the engine.

The dimensions of the engine under consideration are given in the metric system, which will therefore also be used in this calculation. The values are given in kg. and cm. Formulas and tables given by Porter do not require any change, except in one place, which will be stated.

The first problem will be to calculate the first frequency without consideration of the gear drive. The original article reduced the six-cylinder engine to an equivalent three-cylinder system, but since a six-cylinder engine is no more complicated to calculate by the Porter method than a three-cylinder engine, the layout is reduced to its actual arrangement on the engine (see Figure 21-*a*).

From data given, it figures that 8.34 kg. acts at each crank and 450 kg. at the flywheel. These values are those reduced to a common radius, which may be assumed to be 10 cm. At each crank is then acting (the symbols used are those of the paper under discussion), J = 834 kg. cm.^{2} or for six cranks J = 5004 kg. cm.^{2}, or distributed over the length of the shaft, J_s = 41.7 kg. cm. At the flywheel is acting J = 45,000 kg. cm.^{2} The sectional polar moment of inertia of the shaft can be figured from the values given and the assumption R = 10 cm. to J_s = 452.3 cm.^{4}

The system reduces itself then to Fig. 21-*b*. A further simplification is applied, in that part of the flywheel is distributed over the 5-cm. length without mass, amounting to 41.7 × 5 = 209 kg. cm.^{2} The critical speed now figures as follows:

$$J_1 = 125 \times 41.7 = 5213$$

$$C_1 = \frac{820{,}000 \times 452.3}{125} = 2{,}967{,}000$$

$$\phi_1 = \frac{360}{\sqrt{g}} \sqrt{\frac{J_1}{C_1}} = 11.5 \sqrt{\frac{J_1}{C_1}} = 0.482$$

$$-\frac{J_{12}}{J_1} = -\frac{44791}{5213} = -8.59$$

We then read from Table 14, $\phi_1 n = 94.06$, which gives $n = \frac{94.06}{0.482} = 195$ v.p.s., or 11,700 vibrations per minute, against Dr. Schlaefke's value of 11,600 v.p.m.

Let us now find how much the possible error can be due to simplifications. It is

$$\frac{J_{23}}{J_1} = \frac{45{,}000}{5004} = 9 \quad \text{and} \quad \frac{l_2}{l_1} = \frac{5}{120} = 0.0417$$

With these values we can read from Fig. 16 that the error due to solving Fig. 21-*c* instead of *b* is negligible and from Fig. 18 due to solving Fig. 21-*c* instead of *a* is +0.3 per cent, or a total of +0.3 per cent error.

We will now proceed to answer the question put by Dr. Schlaefke as to how much the mass of the gear drive opposite the flywheel end must be to cause the actual frequency on the engine to be only 9700 v.p.s. Dr. Schlaefke takes this mass as μ times the mass of the two cranks, which is 1668 kg. cm.^{2}

Different values for μ must be assumed, but we will take at once the value 0.65, which gave the desired result. For Fig. 21-*d*, the inertia factor of the gear drive 0.65 × 1668 = 1084. Length of added step 1084/41.7 = 26 cm.; J_1 = 5213 + 1084 = 6297; $C_1 = \frac{820{,}000 \times 452.3}{151} = 2{,}456{,}000$; $\phi_1 = 11.5 \sqrt{\frac{J_1}{C_1}} = 0.587$; $-\frac{J_{12}}{J_1} = -7.113$.

We then read from Table 14, $\phi_1 n = 94.85$, which gives $n = \frac{94.85}{0.587} = 161.6$ v.p.s., or 9700 vibrations per minute.

This then means that to satisfy the measurements of the critical speed on the engine proper, the mass of the gear drive amounts to 1.3 times that of one cylinder.

In this last part of the calculation the shaft was simply extended as mass per unit length, while on the engine proper the center of the gear or the load is located 10 cm. from the center of the last bearing, as can be determined from Dr. Schlaefke's layout and $\lambda_x = 0.75\ l$. In order to find how much the error in the mass is due to this assumption, the mass will be reduced backward to a concentrated mass at the end of the original system (Fig. 21-*e*), and then this mass in turn reduced to one located on the centerline of the gear (Fig. 21-*b*). Referring to Fig. 21-*e*, it is

$$J_1 = 1084$$

$$C_1 = \frac{820{,}000 \times 452.3}{26} = 14{,}260{,}000$$

$$\phi_1 = 11.5 \sqrt{\frac{J_1}{C_1}} = 0.1002$$

$$\phi_1 n = 0.1002 \times 161.6 = 16.2$$

Then referring to Table 14, we find the table value $T(\phi_1 n)$ and it is $J'_{l1} = J_1 T(\phi_1 n) = 1084 \times 1.0275 = 1114$. Since $J'_{l1} + J''_{l1} = 0$ (Equation [14]), it is $J''_{l1} = -1114$ kg. cm.^{2}. A simple rule for knowing whether this mass has a positive or

[18] Development Engineer, Fairbanks, Morse & Co., Beloit, Wis. Mem. A.S.M.E.

negative value is that it is positive when the point to which the mass is reduced approaches a node and negative when moved away from a node.

Reducing then the mass to its proper place and referring to Fig. 21-*f*, it is $C_1 = \frac{820{,}000 \times 452.3}{10} = 37{,}100{,}000.$

$$\psi''_{11}n = \sqrt{\frac{1}{2.54}} \sqrt{\frac{J''_{11}}{C_1}}\, 161.6 = 161.6 \times 0.6275 \sqrt{\frac{-1114}{37{,}100{,}000}}$$
$$= 0.556i$$

The factor $\sqrt{\frac{1}{2.54}}$ is introduced for conversion from cm. to inch, Porter's tables being figured for the inch system.

When now reading the table value for $T_0(\psi''_{11}n)$, it must be noted that the value 0.556 is imaginary and therefore Table 13 is to be used. $J''_{01} = 1114\ T_0(0.556\ i) = 1114 \times 0.9693 = 1079.8$, or the error in the mass, by putting it at its proper distance, amounts to $\left(1 - \frac{1079.8}{1084}\right) 100 = 0.4$ per cent, or less than $^1/_2$ of 1 per cent.

The writer believes that he has proved by this discussion and the calculation of an actual case that the method suggested by Mr. Porter shortens the work from one-fifth to one-tenth of that required by present analytical methods. It should be noted that the larger part of this calculation is for the checking of percentage of error due to assumptions made by Porter. This part would not be necessary when using this method in everyday work.

To appreciate Mr. Porter's work fully, it would be worth while to compare the laborious formulas used by Dr. Schlaefke (this is not a criticism of his article, because he uses a method generally accepted today) with the few lines of calculation required for the Porter method. Mr. Porter, who has given us a number of papers on critical speed, deserves great credit for his latest work in this field.

J. Ormondroyd.[19] While the author undoubtedly found great pleasure and use from the development of his simplified methods, the writer is not so sure that this method is of such great importance to the rest of the industry. At the present time methods for calculating critical speeds are in the process of being slowly disseminated throughout the ranks of those engineers who should be able to use them. At this stage it is a far better policy to stay as close to fundamental ideas as possible without any elaboration. The graphical and numerical methods of calculating critical speeds go back, in the final analysis, to the Newtonion equations of motion for the simplified system in question. This system is assumed to be vibrating freely and is also assumed to have no damping forces acting upon it or in it.

Under these assumptions the quantities which appear in the simultaneous equations are the moments of inertia of the masses in the system, the spring constants of the elastic members in the system, the angular coordinates (in radians) of the masses and time. These fundamental equations written with these quantities involved can be recognized by any one in any country who has sufficient dynamical education. A thorough grasp of Newton's second and third laws and a small knowledge of the solution of linear differential equations are all that is needed to the final solutions. The Holzer method can be so used that nothing appears in the tabulation work but the very quantities which appear in the simultaneous equations, and the units of angular measure can be maintained as the radian. This seems to be such a simple procedure that one is surprised at the extensive use of such ideas as equivalent lengths and masses at equivalent radii. Now on top of these elaborations which seem to obscure the real problem, Mr. Porter is proposing a really complicated simplification. He is using a mass of new notations which must be memorized by any engineer who starts out with this method and which are particularly hard to understand for any engineer who has been working in the field with notations grown familiar with years of usage.

If one is starting to calculate the critical speeds of an entirely new engine, Mr. Porter's simplification refers only to a small fraction of the total work required. By far the largest job to be accomplished is the reduction of the actual engine to the equivalent simplified system. It may take anywhere from one day to one week to reduce the reciprocating parts to equivalent flywheels and to calculate the equivalent spring constants between these flywheels by using the data contained in the sketches and drawings of the proposed engine. After the equivalent system is set up, the work of making a preliminary estimate of the lowest natural frequency is very simple. This calculation might take about five minutes. After this the application of the Holzer method to arrive at the lowest natural frequency will take about four complete trials; each trial in the case of a system having eight or nine bodies might take five to seven minutes. In other words, after the system has been set up, it only takes one-half hour to calculate the lowest natural frequency and its corresponding normal elastic curve. Since the second and third natural frequencies require more accurate work in the tabular method, it might be said that two hours more should be added for their calculation when they are needed. Mr. Porter's method simplifies this work, which at the utmost can consume only about two and one-half hours, whereas the work which may take from one day to one week is still the same as before.

Mr. Porter's method of course does have merit in production methods of design or where minor changes to existing engines are very frequent. Most engineers who will have to calculate critical speeds will not run up against mass production of design even in an engine-manufacturing concern. The importance of a common language for all engineers working in a certain field is so great and the widespread use of Holzer's method is such an apparent fact, that the writer believes all efforts should be bent toward disseminating that method rather than attempting to bring out graphical methods or other simplified methods. Naturally the method used by each investigator is a matter of his own taste, and the writer certainly is not the one to oppose publishing any methods of calculation which may be devised. He merely wishes to bring out the fact that he does not consider Mr. Porter's simplified method as simple as the original Holzer method.

M. Stone.[20] The present discusser had a chance to discuss the paper with the author at a joint N.E.M.A.-D.E.M.A. meeting for torsional vibration, and hence is no longer under the handicap of having to force his way through the developments.

The author's notations are rather unnecessarily involved, and the large tables of constants are such that one has a certain hesitancy about reading the paper through. But once this is done, there are certain definite points that are well made by the author.

There is no doubt as to the method of calculating the critical frequencies of a system of n degrees of freedom. This has been

[19] Experimental Division Manager, Westinghouse Elec. & Mfg. Co., South Philadelphia, Pa.

[20] Mechanical Engineer, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. At present on special investigations in Europe.

done in many ways, but the particular case of torsional vibration was first solved and presented satisfactorily by H. Holzer. His assumptions were that an engine can be replaced by a series of discrete inertias (having an average value of the variable reciprocating inertias) connected by massless flexibilities represented by the crankshaft sections between cylinder centers. Calculations based on this method have been checked by actual experiments for the last fifteen years by various investigators in many parts of the world.

In the interest of shortening these calculations, but not losing any appreciable accuracy, the author has replaced the earlier dynamical picture of the engine by one of a distributed mass and flexibility. A real appreciation of what this means can only be obtained by noting the excellent comparison that he has made in Fig. 18, which forms the first convincing argument as to the value of the approximation. The author has further worked out tabulated values to take care of the effects of large concentrated masses in the torsional system, such as flywheels, etc., and has thus reduced the calculation work still further. In an actual case, however, there still remains a considerable amount of judgment that the calculator must exercise in order to represent properly his system dynamically, so that the error shall not be larger than a few per cent. This judgment is of the kind described in the paragraphs following Table 8 where the "total inertia factor for the scavenge pump including the shaft up to the center line of the first bearing is . . . , and corresponds to an increase in length of the main cranks."

Where a calculator has only one type of engine to work with—and has many calculations to do weekly—then the use of the author's tabulations should be a real help, once the proper "feel" is obtained in judging equivalent systems accurately. For calculations of all types of engines and drives, however, the slightly longer but more accurately determined Holzer method is preferable.

One of the most important parts of the calculation of torsional critical frequencies is the proper evaluation of system constants—inertias and flexibilities. While, in general, the discusser agrees with the author's evaluations, the two pertaining to (1) flexible spokes and (2) crankshaft stiffness are not accurately enough determined. In fact, for certain types of crankshafts, the author's rule of taking an equivalent shaft as "3 per cent stiffer than a uniform shaft having the same section as the journal and the same length" may be 40 per cent off. At the Westinghouse Company, the discusser has been making a comparison of all the existing published tests on crankshafts, together with a few unpublished ones, with all the existing methods of calculating crankshaft stiffness. Although the method presented by Constant[21] seems to be the most accurate, due to the correction curves that are necessary to use along with the method, the method of Carter,[22] which is practically as accurate, is preferable. Depending on the type of crankshaft, whether marine, auto, or airplane, the flexibilities, in relation to uniform shaft of section equal to that at the journal and length equal to the actual length, range from 70 per cent to 140 per cent.

The question of the flexibility of the rotor is one that has been only recently appreciated[23] in its full importance. In a case in mind the discusser remembers an instance where the introduction of the generator-rotor flexibility reduced the calculated second critical frequency from 3600 per min. to 2200 per min.; the observed frequency was 2110 per min. The expression for rotor flexibility given in a previous paper[24] has been more recently improved upon, in that it takes into consideration the bending flexibility of the rim against torque. The discusser is sorry that he does not have this formula or its derivation at hand, but it can be found in a report to the previously mentioned N.E.M.A.-D.E.M.A. committee. If the rim is very stiff, i.e., the term $I_r \longrightarrow \infty$, the formula simplifies to that of the author's. However, for the ratio of I_r to I_a (moment of inertia of rim to moment of inertia of arm) that occurs in actual machines, the value of C calculated from the author's formula may be 100 per cent off. A detailed discussion of this point, together with other similar discussion, will appear in a forthcoming paper.

Author's Closure

The author is grateful to the contributors in the discussion for their favorable and stimulating remarks. Apparently the utility of the proposed method is being considered from two different points of view. One of these is the viewpoint of the engine designer who lays out the installation to accommodate satisfactorily the requirements of the engine and driven machinery. The other is the viewpoint of those who design the driven machinery and who wish to check the installation to insure the safety of their own equipment. In the latter case, some of the discussers feel that the time element in making a calculation is not an important consideration, the principal requirement being that the results are reliable. In the former case, however, it is often necessary to check the frequencies of many different combinations in order to find the best arrangement of the machinery. If this kind of work is carried out thoroughly, the time element in making the calculations becomes an important consideration. It is gratifying to see by the discussion that the engine designers are favorably inclined toward the proposed method.

There are several ways in which the designer is forced to approach the torsional-vibration problem. The following is a description of how it may be given consideration from the beginning of the design work. The description is divided into two parts: (1) preliminary calculations, and (2) calculations for special arrangements.

1 *Preliminary Calculations.* Suppose that a line of engines are to be built having a certain cylinder size and consisting of anywhere from three to eight cylinders. Suppose also that these engines are to be used in any arrangement where Diesel power is desired.

In the first steps of the design work, the weights of the moving parts will be calculated for the purpose of determining the stresses due to the reciprocating and rotating parts. These weights will also be used in designing the counterweights for the three and four cylinder sizes and for the scavenge pump and air compressor. Later the flywheel sizes are determined for the various types of service in which the engines will be used.

Thus in the preliminary design calculations, a greater part of the work in calculating the engine factors for the torsional vibration problem is already made in determining the unbalanced forces and stresses in the engine.

Suppose that many of the adaptations of these engines will be in electric installations driving generators or alternators, and also in marine installations direct connected to marine propellers. The most probable electric equipment will be assumed, as will also several typical marine installations for each of the six engines in the new line.

The critical speeds for these various arrangements will then be calculated. In this way the designer sees whether he can expect to overcome the vibration difficulties in the various engines and

which of the engines will cause him the most trouble. He can then decide if the crankshaft diameter should be changed, or if other changes are necessary to give a proper control of the critical speeds.

Finally the line of engines is put into production. The actual weights of the connecting rods and reciprocating parts are obtained, and the preliminary inertia factors of the engines are modified to agree with these values.

2 *Calculations for Special Arrangements.* When the desired adaptation of the Diesel engine is determined for each customer, the frequency calculations are made for the most obvious arrangement. In many cases, however, this is just the beginning of the work, as it often happens that the most obvious arrangement does not give favorable locations for the critical speeds.

Various arrangements are then calculated. For example, the attached shafting may be changed; the flywheel may be altered;

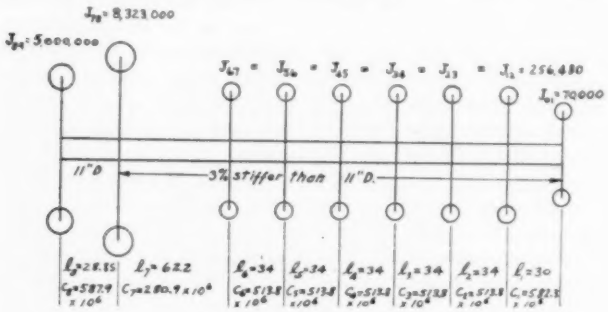

FIG. 22

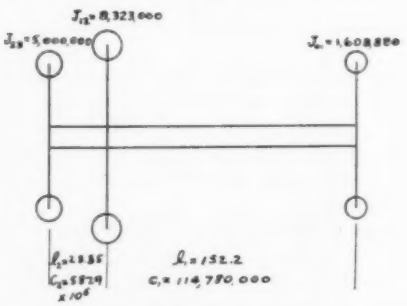

FIG. 23

a small flywheel may be located to advantage at some point, particularly at the engine end opposite the flywheel; or other changes may be considered that are apparent in special installations. Even the main-engine counterweights may be altered or, in especially difficult installations, counterweights may be added on those engines that are inherently balanced.

After a suitable arrangement has been found, the maximum amplitudes and resonance curves may be calculated as a final check on the installation.

Sometimes it is advantageous to draw curves as illustrated in Fig. 13 to give the natural frequencies of any likely combination of the driven machinery.

In the type of design work described above, the frequency calculations require a large percentage of the time given to the torsional-vibration problem. The proposed method of calculation was developed to handle work of this kind in order to meet production methods of manufacturing with speedier methods of calculation and without loss of accuracy.

Most of the discussers have acknowledged that the proposed method has merit when used as just described. Messrs. Hogan and Ormondroyd, however, feel that the amount of time required for the frequency calculations is small in comparison with the time required for the whole calculation. While this idea may be true for those making a final check on a complete installation, it is seldom true for those laying out new designs.

Referring to Mr. Hogan's comments, he states that the proposed method merely introduces another complication which obscures the physical picture, and that one of the best reasons for the use of Holzer's method is that it aids the engineer in getting a clear mental picture of the phenomenon which prevents any numerical errors that tend to creep in. He explains the approximate solution used in the Holzer method and states that the value obtained by the approximate solution is usually very close to the exact value for the first frequency, while that for the second is generally in error.

The last statement mentions an important characteristic, but, contrary to Mr. Hogan's idea, it is true about as often as it is false. A little work with the proposed method, as illustrated below, will show this and will also show the reason. Since Mr. Hogan has used Holzer's method for several years, this would indicate that Holzer's method does not give as good a mental picture of the phenomenon as the proposed method.

Fig. 22 shows the numerical example given in the paper (refer to Figs. 11 and 12) arranged for solution by Holzer's method. The flywheel inertia factor is 8,323,000 lb-in.^{2}, since the value of 8×10^6 as shown in Fig. 12 was obtained by making a deduction from the actual value to spread over a short length in step No. 1 to make the uniform shaft representing the engine extend to the flywheel. This was mentioned in the second paragraph under Table 8. The value of the deduction was $45.2 \times 7544 - 43.85\ (11)^4/36 = 323{,}000$ lb-in.^{2}

Fig. 23 shows this system arranged for the approximate solution by the well-known formula for a three-mass system. The formula will be used as it is given, page 54, Equation [121] of the author's paper APM-50-8, Trans. A.S.M.E.

$$\frac{C_1(J_{01}+J_{12})}{2J_{01}J_{12}}+\frac{C_2(J_{12}+J_{23})}{2J_{12}J_{23}}=\frac{114.78\times 9.932}{2\times 1.6089\times 8.323}+\frac{587.9\times 13.323}{2\times 8.323\times 5}=136.67$$

$$\frac{(J_{01}+J_{12}+J_{23})C_1C_2}{J_{01}J_{12}J_{23}}=\frac{14.932\times 114.78\times 587.9}{16.6089\times 8.323\times 5}=15{,}049$$

$$n = 3.1266\sqrt{136.67 \pm \sqrt{(136.67)^2-15{,}049}}$$

$$= 3.1266\sqrt{136.67 \pm 60.25} = 3.1266\times(7.642 \text{ or } 14.033)$$

$$= 23.89 \text{ or } 43.88$$

We therefore assume $p^2 = (2\pi n)^2 = 23{,}000$ for the first tabular solution by the Holzer method. The calculations are given in Table 15a. The value I in this table is equal to J/g. The assumed value of p^2 is seen to be low. Next we take $p^2 = 25{,}000$ as shown in Table 15b. The value of p^2 is still too low. The next trial value by extrapolation would be $p^2 = 36{,}440$, but anticipating that this value is high, we assume $p^2 = 30{,}000$. Table 15c gives the calculations. Again, by extrapolation, p^2 would be 35,250. Assuming $p^2 = 35{,}000$, another table (15d) is calculated. Interpolating between $p^2 = 30{,}000$ and 35,000, we get $p^2 = 34{,}780$, which gives $n = 29.68$ for the first frequency. It is to be noted, however, that even though our interpolated value of p^2 is correct, we shall have to make another tabular calculation to obtain correct θ-values for the relative-amplitudes curve.

The two tabular calculations necessary for the second frequency solution are given in Tables 15c and 15f. The interpolated value of p^2 is 76,230, which gives $n = 43.94$.

The calculations necessary to obtain these frequencies by the proposed method are given in Table 7.

Summarizing the results, we have:

VALUES OF n IN VIBRATIONS PER SECOND

	Holzer's Method		
	Approx. solution	Accurate method	Proposed method
First frequency.....	23.89	29.68	29.67
Second frequency.....	43.88	43.94	44.07

It will be observed that the first frequency by the approximate solution in Holzer's method is 19.5 per cent in error, while the second frequency is 0.9 per cent in error. The reason that this is contrary to Mr. Hogan's statement is that the engine and flywheel have a larger influence in determining the first frequency than the other parts, and that the flywheel, alternator shaft, and alternator have a larger influence in determining the second frequency than the engine. Thus the rough approximation of replacing the engine with a single concentrated mass at the center of gravity of the inertia factors on the engine side of the flywheel gives only a rough approximation to the first frequency, whereas the second frequency is obtained more accurately by the same approximation.

This fact is easily seen when using the proposed method, thus: First, consider the frequency of the engine and flywheel with the alternator cut off. In this case $n = T^{-1}(-8/1.95) \div 3.113 = 31.5$, which is only 6 per cent from the correct value of the first frequency. Then consider the frequency of the flywheel and alternator with the engine cut off. In this case $n = T_0^{-1}(-8/5) \div 0.09221 = 43.2$, which is only 2 per cent from the correct value of the second frequency.

Another way of seeing this is described at the bottom in the third paragraph below Table 8, where a reference is made to Fig. 15.

The idea is also illustrated in Fig. 13. It will be noted in this figure that portions of the curves are only slightly inclined to the natural-frequency axis and that other portions rise very swiftly from this axis. In the former case where the curves are only slightly inclined, the frequency changes rapidly for changes in the alternator-shaft stiffness, while in the latter case changes in the extension shaft have very little influence on the frequency. The former case is the one that Mr. Hogan has noted, whereas the latter case, which is equally likely to occur, corresponds to the numerical example given above.

The saving of work when using the proposed method is also illustrated by the numerical example. The complete calculations necessary to get the first and second frequencies by Holzer's method are given in Tables 15a to 15f, not counting the calculations required for the approximate solution. Each of these tables requires 41 arithmetical operations and corresponds to one line across Table 7, or 5 arithmetical operations for the proposed method. Therefore not only is the amount of work required for the proposed method less than one-eighth that for Holzer's method in this case, but the possibility of numerical errors is also reduced by the same ratio.

Mr. Hogan mentions that having the calculations by Holzer's method, no special calculations are necessary in order to draw the relative displacement or elastic curve, also that in the case of the proposed method another calculation must be made in order to determine it. The actual facts of the case, however, may be seen by a reference to the numerical example just described. In working this problem by Holzer's method we needed four tables (15a to 15d) for the first frequency and two tables (15c and 15f) for the second frequency to obtain accurate values of p. We do not have tables for these accurate values, because they were obtained by interpolation. Therefore in order to obtain the relative-amplitude curves for the first and second frequencies, we shall have to calculate two more tables having 41 arithmetical operations in each table. The proposed method requires two multiplications and one division to obtain the relative-amplitude curve for each frequency, giving the amplitudes over the engine as ordinates of a sine curve.

Mr. Hogan also brings up the point that in order to carry out the calculations by the proposed method, the tables and data of the paper must be on hand. One could also say this was a disadvantage for the ordinary trigonometric tables or even for the slide rule.

The author agrees with Mr. Hogan that spoke flexibility is often of considerable importance, and has tried to point this out in the paper. Further discussion of this point is given later.

In regard to crankshaft stiffness, the author prefers using factors for similar crankshafts that he has tested rather than using a formula. For any new type of crankshaft, experience has shown that the importance of the torsional-vibration problem warrants a test to determine its stiffness.

The author appreciates Dr. Wydler's comments. He hopes that he may have opportunity to apply his method as suggested.

The tables of results given by Messrs. Geittman and Anderson are interesting. The latter gives a check between Holzer's method and the proposed method that he obtained on five different installations. The former gives a comparison between calculated results and the actual frequencies that he has also observed on five installations.

Mr. Dashefsky mentions that some error of approximation in

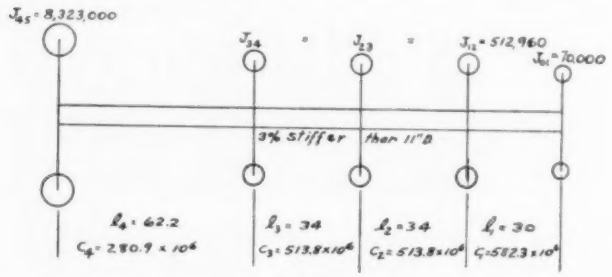

FIG. 24

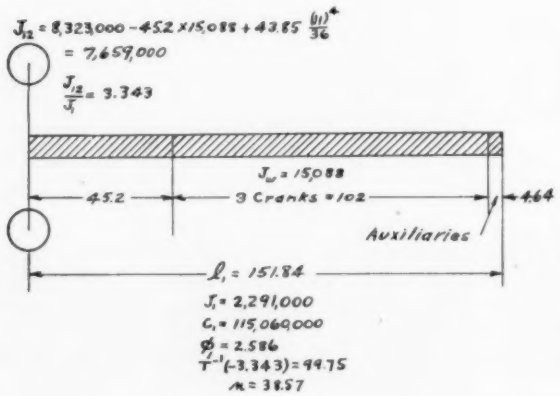

FIG. 25

the calculated frequency may be introduced due to interpolation on trial values of n. This error, however, should be no greater than five parts in 20,000, which in general is the maximum error for which the tables were designed. If there is any doubt that the interpolated value is not correct, another calculation should be made.

The critical values of n mentioned by Mr. Dashefsky are seldom troublesome. They can always be handled in the proposed tabular solutions by assuming one of the factors of the installation as a variable and computing values of n corresponding to different values of the assumed variable.

Mr. Tulus states that in an engine with only a few cylinders the accuracy of the proposed method will not be nearly as good as the Holzer method. This idea was discussed in the paper and the statement was made in the second paragraph following Fig. 9 that "since engines with a small number of cylinders usually have counterweights at each crank web, it seems probable that the actual installation is more like the uniform-shaft system than the system of concentrated masses." We have examined

this point very carefully and believe that Mr. Tulus is not correct in his statement of the case. For example, consider a three-cylinder engine of the same design as that shown in Fig. 11, driving a flywheel-type generator having an inertia factor of 8,323,000 lb-in.^{2} The usual engine counterweights which are placed on each web practically double the inertia factor at each

cylinder. We shall therefore assume that each counterweight has an inertia factor of 128,240 lb-in.[2]

Fig. 24 shows the equivalent arrangement for solution by Holzer's method. The solution is given in Tables 16a and 16b.

The solution by the proposed method is given in Fig. 25.

Now, consider the inertia factors at each crank as follows:

(1) Inertia factor at the center line of the crankpin.

(*a*)	Piston and connecting rod =	120,050
(*b*)	8 in. of crankpin = 0.8 × 36,600 =	29,280
	Sum =	149,330

(2) Inertia factor at the center of each web.

(*a*)	One web 94,950/2 =	47,475
(*b*)	1/2 of journal = 4880/2 =	2,440
(*c*)	One inch of crankpin =	3,660
(*d*)	One counterweight =	128,240
	Sum =	181,815

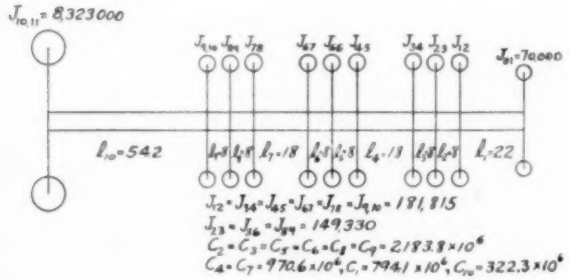

FIG. 26

The length between the center line of the piston and the center of the web equals 8 in., and between the centers of adjacent webs of different cranks is 18 in.

The equivalent arrangement is shown in Fig. 26 and the solution by Holzer's tabular solution is given in Tables 17a and 17b.

The results of the solutions for the three types of equivalent systems considered for this three-cylinder engine are given in Table 18.

Which of these methods gives the more nearly correct result is difficult to say, but it is quite apparent that either (2) or (3) of Table 18 is closer to the actual shaft arrangement than (1). This shows that, in the last analysis, actual fact is contrary to Mr. Tulus' statement.

TABLE 18

	Method	n	Per cent difference relative to (3)
(1)	Holzer's method	38.36	0.47
(2)	Proposed method	38.57	0.08
(3)	Concentrated-mass solution considering three masses per crank	38.54	..

The elastic effects of press fits, clamped fits, and shrink fits vary considerably even in identical installations. We have observed these effects in twisting tests and vibration tests, and recommend the working rules given in the paper. Some work has also been done in treating this problem theoretically.[25]

Mr. Tulus mentions the problem of how far the operating speeds must be kept from any one of the major orders of vibration. This depends upon such limiting factors as excessive stresses, undue wear of parts, noise, flickering lights, or other kinds of objectionable effects due to torsional vibration. The calculation of the range of critical speeds was considered in a previous paper.

The author appreciates Mr. Schreck's addition to the discussion. The example worked out by Mr. Schreck shows very clearly the simplification of the work involved in calculating the natural frequencies by the proposed method.

Mr. Stone states that there still remains a considerable amount of judgment to be used by the calculator in order to properly represent his sytem dynamically, so that the error shall not be larger than a few per cent, and he quotes as proof to his statement the treatment of the scavenge-pump inertia as explained in the numerical example given in the paper.

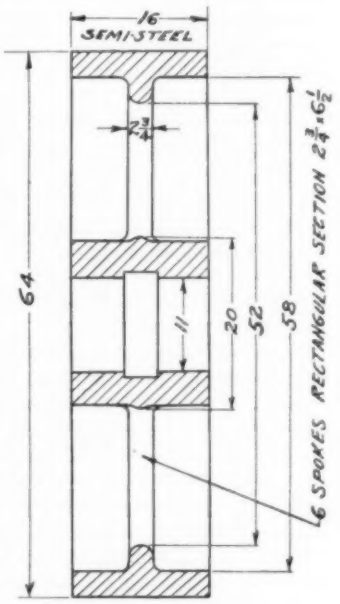

FIG. 27

Apparently Mr. Stone has overlooked Fig. 17 and the explanation of this figure given in the first paragraph below Fig. 9. When one is reducing the actual system to a simpler one for mathematical treatment, it is recommended that he read over the section of the paper entitled "Determination of Equivalent System."

The author does not agree with Mr. Stone's expression, the "more accurately determined Holzer method." The fact is that the theory of the vibration of uniform shafts with mass is just as fundamental and just as accurately determined as the theory underlying Holzer's method. In regard to the accuracy of the results, we have shown both in the paper and in the discussion that there is no practical difference between Holzer's method and the proposed method.

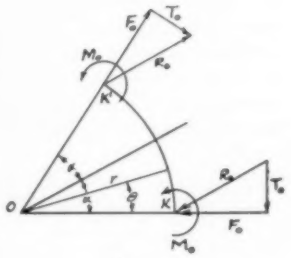

FIG. 28

Mr. Stone brings up two points which he says are not accurately enough determined: (1) flexible spokes and (2) crankshaft stiffness. In regard to crankshaft stiffness, Mr. Stone has apparently misunderstood the statements in the paper. The author would like to point out that he has quoted only the last half of a sentence, the whole of which reads, "A crankshaft having the general proportions shown in Fig. 9 when turning in its bearings under operating conditions is about 3 per cent stiffer than a uniform shaft having the same length and the same section as the journal." The author recognizes that crankshafts of widely different designs will have different values for their stiffness factors. In fact, in the sentence following the one quoted above, he refers to test results where the comparative stiffness ratio varies from less than one to 1.25.

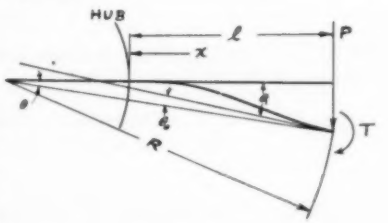

FIG. 29

Several of the discussers, including Mr. Stone, refer to Carter's

[25] Verhandlungen des 2-internationalen Kongresses für technische Mechanik, Zurich, 1926: "Ueber die Torsion von Schrumpfverbindungen," von G. Eichelberg, Winterthur.

formula for crankshaft stiffness. The statement is made that tests have proved it to be sufficiently accurate for engineering calculations, especially in the Diesel-engine field. Undoubtedly Carter's formula is a remarkably good one considering the number of variables involved, and furthermore it does have its uses in evaluating the stiffness factors for crankshafts of new designs. It should be recognized, however, that it is an approximate formula and that the stiffness values of actual shafts do vary considerably from those computed. In this respect Carter makes the following statement: "Taking the test results to be exact, the range of error in the calculated stiffness values is from 6.4 per cent low to 8.2 per cent high for the marine shafts, 10.2 per cent low and 4.8 per cent high for aircraft shafts, and 3.8 per cent low and 13 per cent high for car shafts; thus all the results lie between 10.2 per cent low and 13 per cent high."

Applying Carter's formula to the crank shown in Fig. 9, the comparative stiffness factor works out to be 0.872. This value from test results observed by the author should have been 1.03, which in this case shows an error of 15.3 per cent in the value from Carter's formula.

The large number of variables affecting the crankshaft-stiffness problem include not only the crankshaft dimensions but also the bearing restraint. The latter variable is dependent upon the stiffness of the engine frame, etc. About the only way to get accurate stiffness factors for crankshafts of radically new designs is to obtain them from the engine itself after the new design is built. At the present time, factors obtained from formulas must be considered as only approximate.

The other point mentioned by Mr. Stone is the stiffness factor for a heavy elastic ring attached to the shaft by flexible spokes. Formula [26] applies to a heavy stiff ring attached to the shaft by flexible spokes. In certain special designs it is possible that the elasticity of the ring will be an appreciable amount that should be considered. In this case the proper formula is easily obtained from the usual theory for the bending of nearly circular rings in one plane. The resulting expression for the stiffness factor, C, of the rim relative to the hub is given below and the derivation is given at the end of the closure:

$$C = \frac{12\,NEIr}{l(1+K)}\left(r + \frac{1}{3r} - 1 + \frac{rK}{4}\right) \quad \ldots\ldots\ldots [31]$$

where

$$K = \frac{rI}{I_1}\left(\frac{\beta - \sin\beta}{1 - \cos\beta}\right)$$

The symbols are the same as those for Equation [26] with the addition of the following values:

β = $2\pi/N$, or the angle between spokes (radians)
I_1 = rectangular moment of inertia of the ring section (in.^{4})

Since the radial thickness of the ring is assumed to be small, the value of R in the expression $r = R/l$ is taken to be the same as before, namely, the outer radius of the spokes. Values of $(\beta - \sin\beta)/(1 - \cos\beta)$ for various numbers of spokes are given in Table 19.

TABLE 19

Number of spokes	$\frac{\beta - \sin\beta}{1 - \cos\beta}$
4	0.57080
6	0.36234
8	0.26730
10	0.21224
12	0.17614

Fig. 27 shows the spider of the alternator rotor that was used in the numerical example of Fig. 11.

(*a*) *Considering the rim stiff,*

$$N = 6,\ E = 15 \times 10^6 \text{ lb. per sq. in.},\ I = \frac{1}{12}\,2.75(6.5)^3$$
$$= 62.93 \text{ in.}^4,\ R = 26 \text{ in.},\ l = 16 \text{ in.},\ r = 1.625$$
$$r + \frac{1}{3r} - 1 = 0.8301$$

Therefore from Formula [26]

$$C' = 12 \times 6 \times 15 \times 10^6 \times 62.93 \times 1.625 \times 0.8301 \div 16$$
$$= 5730 \times 10^6$$

which is equivalent to 2.960 in. of 11-in.-diameter shafting. It will be noted that this was given as 3 in. in Fig. 11.

(*b*) *Considering elasticity of rim,*

N, E, I, R, l, r, and $r + \frac{1}{3r} - 1$ as before,

also

$$I_1 = 16 \times 3\left[\frac{(3)^3}{12} + (0.44)^2\right] + 2.75 \times 3\left[\frac{(3)^3}{12} + (2.56)^2\right]$$
$$= 105.55 \text{ in.}^4$$
$$K = 1.5294 \times 78.60 \times 0.3623 \div 105.55 = 0.4126$$
$$\frac{rK}{4} = 1.5294 \times 0.4126 \div 4 = 0.15776$$
$$C' = \frac{12 \times 6 \times 15 \times 10^6 \times 62.93 \times 1.625}{16 \times 1.4126}\,(0.8301 + 0.15776)$$
$$= 4827 \times 10^6$$

which is equivalent to 3.514 in. of 11-in.-diameter shafting.

The error involved in the length of step No. 2 of Fig. 11 due to assuming the rotor rim stiff is 0.554 in. or 1.9 per cent, which is much less than the variation that can occur in the effective length of the shaft under the hub of the rotor. In this case it is evident that the elasticity of the rim is of no consequence. This condition is typical of a great many actual machines. Where additional elasticity in the rim is anticipated, however, the author agrees with Mr. Stone that this condition should also be investigated.

In this discussion, several references have been made to Holzer's method of calculating natural frequencies. The author wishes to state that he had done so for the sake of comparison and with no intention of criticizing this method.

Heavy Elastic Ring Connected to Shaft by Flexible Spokes. The theory of the bending of nearly circular rings in one plane has been very completely treated by Prescott ("Applied Elasticity," Longmans, Green and Co., 1924, pp. 282–318). The rings may be closed or open; the general equations will also apply to rods whose central lines form arcs of circles or whole circles.

In summarizing the general equations given by Prescott, we shall use the symbols as he defined them.

The circle which nearly coincides with the central line of the ring is taken as a curve of reference. The radius of this circle is r. The polar coordinates of a point on the reference circle are (r, θ) with the pole at the center of the circle. The symbols M, F, T denote the bending moment, the shearing force, and the tension at any point. The external forces per unit length of the ring are p acting radially toward the center and q acting tangentially in the direction in which $d\theta$ is measured. The values of p and q for the problem at hand may be taken equal to zero. The change in the value of r for any point in the strained state is u.

The resulting equations which apply to the present problem are obtained by putting p and q equal to zero in the general equations given by Prescott. This gives

$$T = \frac{dF}{d\theta} \quad [32]$$

$$F = -\frac{dT}{d\theta} \quad [33]$$

$$F = \frac{1}{r}\frac{dM}{d\theta} \quad [34]$$

$$M = -\frac{EI}{r^2}\left(\frac{d^2u}{d\theta^2} + u\right) \quad [35]$$

The equations combine to give

$$\frac{d^3u}{d\theta^3} + 2\frac{d^2u}{d\theta^2} + \frac{du}{d\theta} = 0$$

whose general solution may be written

$$u = A + (B + C\theta)\sin\theta + (H + K\theta)\cos\theta \quad [36]$$

The problem of finding the deflection of the ring under the action of the couples acting at the ends of the spokes merely requires the evaluation of the five constants of integration satisfying the end conditions of each segment of the ring. In Fig. 28, KK' represents the segment of the ring between spokes, OK is the initial line for θ, and $\theta = 2\alpha$ is the angle between spokes, with one spoke at OK and the next at OK'.

The two couples M_0 are held in equilibrium by the couple $2R_0r\sin\alpha$. Thus $R_0 = M_0/(r\sin\alpha)$. Resolving R_0 along and perpendicular to the radius $F_0 = M_0/(r\tan\alpha)$ and $T_0 = M_0/r$.

Therefore the conditions to be satisfied at the ends of the segment are

(1) $M = M_0$	(1a) $M = -M_0$
(2) $F = \frac{M_0}{r\tan\alpha}$	(2a) $F = \frac{M_0}{r\tan\alpha}$
(3) $T = \frac{M_0}{r}$	(3a) $T = -\frac{M_0}{r}$
(4) $u = 0$	(4a) $u = 0$
at $\theta = 0$	at $\theta = 2\alpha$

(5) $\frac{du}{d\theta}$ (at $\theta = 0$) $= \frac{du}{d\theta}$ (at $\theta = 2\alpha$)

Differentiating Equation [36] gives

$$\frac{du}{d\theta} = (C - H - K\theta)\sin\theta + (B + K + C\theta)\cos\theta \quad [37]$$

$$\frac{d^2u}{d\theta^2} = -(B + 2K + C\theta)\sin\theta + (2C - H - K\theta)\cos\theta \quad [38]$$

Combining [35], [36] and [38] gives

$$M = -\frac{EI}{r^2}(A - 2K\sin\theta + 2C\cos\theta) \quad [39]$$

Differentiating [39] gives

$$\frac{dM}{d\theta} = \frac{2EI}{r^2}(K\cos\theta + C\sin\theta) \quad [40]$$

Combining [34] and [40] gives

$$F = \frac{2EI}{r^3}(K\cos\theta + C\sin\theta) \quad [41]$$

Differentiating again

$$\frac{dF}{d\theta} = \frac{2EI}{r^3}(-K\sin\theta + C\cos\theta) \quad [42]$$

Combing [32] and [42] gives

$$T = \frac{2EI}{r^3}(-K\sin\theta + C\cos\theta) \quad [43]$$

Putting condition (2) in Equation [41] gives

$$\frac{M_0}{r\tan\alpha} = \frac{2EIK}{r^3}, \text{ or } K = \frac{r^2M_0}{2EI\tan\alpha}$$

Putting condition (3) in Equation [43] gives

$$\frac{M_0}{r} = \frac{2EIC}{r^3}, \quad \text{or } C = \frac{r^2M_0}{2EI}$$

Putting condition (1) in Equation [39] gives

$$M_0 = -\frac{EI}{r^2}\left(A + \frac{r^2M_0}{EI}\right), \text{ or } A = 0$$

Putting condition (4) in Equation [36] gives $H = \theta$

Putting condition (4a) in Equation [36] gives

$$0 = \left(B + \frac{r^2M_0\alpha}{EI}\right)\sin 2\alpha + \frac{r^2M_0\alpha\cos 2\alpha}{EI\tan\alpha}$$

or

$$B = -\frac{r^2M_0\alpha}{2EI\sin 2\alpha}$$

Summarizing the constants of integration,

$$\left.\begin{aligned} A &= 0 \\ B &= -\frac{r^2M_0\alpha}{2EI\sin^2\alpha} \\ C &= \frac{r^2M_0}{2EI} \\ H &= 0 \\ K &= \frac{r^2M_0}{2EI\tan\alpha} \end{aligned}\right\} \quad [44]$$

Placing these constants in the above equations gives the desired solution of the deflection of the ring under the action of couples at the ends of the spokes.

If $\frac{du_0}{d\theta}$ is the value of $\frac{du}{d\theta}$ at $\theta = 0$ or 2α,

$$\frac{du_0}{d\theta} = B + K$$

$$= -\frac{r^2M_0\alpha}{2EI\sin^2\alpha} + \frac{r^2M_0}{2ET\tan\alpha}$$

$$= -\frac{r^2M_0}{2EI}\left(\frac{\alpha}{\sin^2\alpha} - \frac{1}{\tan\alpha}\right)$$

$$\frac{1}{r}\frac{du_0}{d\theta} = -\frac{rM_0}{2EI}\left(\frac{2\alpha - \sin 2\alpha}{1 - \cos 2\alpha}\right) \quad [45]$$

Up to this point we have carried out the solution with the symbols used by Prescott. In the remainder of the solution, Prescott's definitions for these symbols will not be retained.

Consider the equilibrium of a spoke. Let the axis of any spoke before strain be taken as a reference line with x measured along this line from the hub. Let the hub be held fixed and the ring be twisted through an angle θ; also, as shown in Fig. 29, let

P = tangential force acting on one spoke at the ring
T = couple at the ring
R = radius to ring
l = length of spoke
r = R/l
f = linear deflection of end of spoke
f_1 = linear deflection at x
E = modulus of elasticity in tension
I = rectangular moment of inertia of the spoke section
I_1 = rectangular moment of inertia of the ring section
θ_1 = angle of tangent at the end of the spoke at the ring = $\theta + \theta_0$
N = number of spokes
Q = torque transmitted by N spokes
β = angle between spokes = $2\pi/N$

Putting M_0 in [45] equal to $T/2$, $2\alpha = \beta$, $r = R$, $I = I_1$, and $\frac{1}{r} = \frac{du_0}{d\theta} = \theta_0$, we have

$$\theta_0 = -\frac{RT}{4EI_1}\left(\frac{\beta - \sin\beta}{1 - \cos\beta}\right)$$

Hence

$$\theta_1 = \theta - \frac{RT}{4EI_1}\left(\frac{\beta - \sin\beta}{1 - \cos\beta}\right) \quad [46]$$

The bending moment on the spoke at a distance x from the hub is

$$M = T + P(l - x)$$

so that

$$EI\frac{d^2f_1}{dx^2} = T + Pl - Px$$

Integrating, this gives

$$EI\frac{df_1}{dx} = (T + Pl)x - \frac{Px^2}{2}$$

$$EIf_1 = (T + Pl)\frac{x^2}{2} - \frac{Px^3}{6}$$

where the constants of integration are zero, since $\frac{df_1}{dx} = 0$ and $f_1 = 0$ at $x = 0$.

At $x = l$, the slope of the deflection curve is $\tan\theta_1$ which can be taken as θ_1 since θ_1 is small. Therefore the last two equations can be written as

$$EI\theta_1 = Tl + \frac{Pl^2}{2}$$

$$EIf = \frac{Tl^2}{2} + \frac{Pl^3}{3}$$

Solving these two equations for P and T and putting $R\theta = f$ and $r = R/l$, gives

$$P = \frac{12EI}{l^3}\left(r\theta - \frac{\theta_1}{2}\right) \quad [47]$$

$$T = -\frac{12EI}{l}\left(\frac{r\theta}{2} - \frac{\theta_1}{3}\right) \quad [48]$$

Using Equations [46], [47] and [48] we may eliminate θ_1 and obtain P and T in terms of θ. This gives

$$P = \frac{12EI\theta}{l^2(1 + K)}\left(r - \frac{1}{2} + \frac{rK}{4}\right)$$

$$T = -\frac{12EI\theta}{l(1 + K)}\left(\frac{r}{2} - \frac{1}{3}\right)$$

where

$$K = \frac{rI}{I_1}\left(\frac{\beta - \sin\beta}{1 - \cos\beta}\right)$$

The torque transmitted by N spokes is

$$Q = N(T + PR)$$

$$= -\frac{12NEI\theta}{l(1 + K)}\left(\frac{r}{2} - \frac{1}{3}\right) + \frac{12NEIr\theta}{l(1 + K)}\left(r - \frac{1}{2} + \frac{rK}{4}\right)$$

Therefore, since the stiffness factor C for the rim relative to the hub is Q/θ, we have

$$C = \frac{12NEIr}{l(1 + K)}\left(r + \frac{1}{3r} - 1 + \frac{rK}{4}\right)$$

where

$$K = \frac{rI}{I_1}\left(\frac{\beta - \sin\beta}{1 - \cos\beta}\right)$$

The Diesel-Engine Tractor and Excavator

By C. G. A. ROSEN,[1] SAN LEANDRO, CALIF.

Special emphasis is given in this paper to the combustion process for Diesel-tractor service. A variety of fuel systems were installed and tested in a rugged engine of flexible design. General results of the tests are given. Accessories are considered extremely important in tractor service, and the author discusses air cleaners, oil filters, and engine starters. The problems discussed can be applied to other traction equipment including excavators. Reliability at all loads and speeds within the engine operating range is paramount, and maintenance costs must be kept low.

IF A MECHANICAL product is to satisfy economic necessity, service demands must dictate engineering thought. The operating-field problems will then be reflected in the manufactured article. Consider, for example, the tractor. The withdrawal of tractors from any "Caterpillar" warehouse may place one machine in the hands of native labor in the torrid swamps of an African jungle; another tractor may be harnessed to a snow-plow to clear the roads of civilization in freezing weather; a third unit may be destined to travel in an enveloping cloud of dust over fields of pulverized soil under the control of a begoggled and masked operator; still a fourth tractor may be called to drag logs in the woods, careening and zooming drunkenly over rough country, sometimes up grades as steep as 75 per cent; another may be forced to consume Russian kerosene of an initial boiling point of 340 deg. and an end point of 610 deg.; a Cuban purchasing agent may require a sixth tractor to deliver its power on fuels of 104 deg. initial boiling point, but an end point of 600 deg. These six tractors from the same assembly line are expected to perform continuous heavy duty under diametrically opposite circumstances.

From such fields and others the call is heard for the Diesel-engine tractor. Two avenues of economic influence are revealed in the demand:

1 The need for an internal-combustion power unit which will burn fuels economically available at points of world distribution, which fuels are not readily combustible in carburetor engines

2 The need for an internal-combustion power unit which will have such economical consumption of cheap fuels as to cause a reduction in operating cost when compared with carburetor engines.

The Diesel engine is a prime mover designed essentially to show high economy in the consumption of cheap-grade fuels. That is its inherent reason for existence. The Diesel engine fitted to a tractor must be a satisfactory oil-burning unit. Its practical value, however, cannot be confined to those districts where specification fuels are obtainable. Desirable as specification fuels are, the use of available fuels cannot be disqualified by the manufacturer. In communities where gasoline sells for 75 cents to 80 cents a gallon, the economical consumption of cheaper grade fuels offers the high-speed Diesel engine its most lucrative field of economic reward.

The Diesel-engine excavator likewise shares this economic promise. It is also a product of world-wide distribution and, like the tractor, is encumbered with fuel-burning problems. The Diesel-driven excavator is subject to high peaks of overload and must qualify for variable-load operation. Sudden demands of power are required of the internal-combustion unit, and the questions of labor are pertinent. Although the excavator Diesel need not of necessity be light in weight, yet it has definite limitations as to space. The high-speed Diesel is therefore desirable for this type of service, particularly in the smaller units.

The tractor Diesel engine is also to be classed with high-speed engines and medium light-weight construction. Continuous power must be developed at relatively high b.m.e.p. in designs weighing 40 lb. per b.hp. or under. In substituting a Diesel engine for a gasoline engine of the same number of cylinders, the speed of the Diesel must be increased from 20 to 30 per cent for the same weight limitations. It therefore is safe to say that the tractor engine is subjected to all of the problems incumbent upon the excavator engine, but is penalized by even more severe service demands. Some commercial engines offered for excavators are reasonably successful, but are not sufficiently satisfactory for the more exacting duties required of the tractor.

The track-type tractor is a combination of many difficult problems. It must be capable of continuous operation at full load for indefinite periods of time, in all sorts of weather and environments, and in the hands of labor capable of inflicting an unusual amount of abuse. For the purpose of illustrating the severest problems involved in mobile industrial equipment, the tractor Diesel engine will be used as an example.

In view of the demands made for Diesel track-type tractors, the Caterpillar Tractor Company, about three years ago, organized a definite program of Diesel-engine investigation. The examination of the oil-engine field at that time revealed the fact that no unit was available which could be installed directly to satisfy caterpillar-tractor service. A number of commercial high-speed engines were purchased both here and abroad, to determine their possibilities for tractor use. Other units were observed under field operation and inspections were made of high-speed engines applied to extraneous services. Careful tests were made to obtain the status of commercial operating

---

[1] Diesel Engineer, Caterpillar Tractor Co., Mem. A.S.M.E. The author was graduated from Cogswell Polytechnic College and University of California with degrees of B.S. and M.E. Served in machine shop, forge shop, foundry, and drafting room on oil-engine construction and repair. Was Diesel engineer with Dow Pump & Diesel Engine Co., 1915 to 1922, terminating service as chief engineer. Engaged in practice as consulting and research engineer, 1922 to 1929, on design for Diesel-engine builders, on maintenance and installation for motorship and power-plant operators, on installation for Diesel-engine accessory and auxiliary-equipment manufacturers. Was instructor in Diesel engines for University of California Extension Division for five years. Served as Pacific Coast editorial representative for *Motorship*. Contributed articles on Diesel engines for *The Log* and *Pacific Marine Review*. Author of correspondence-course textbook "Marine Diesel Engines," published by the American Society of Marine Engineers, and co-author of University of California correspondence course on Diesel engines. From 1929 to the present, engaged in the development of mobile Diesels for Caterpillar Tractor Company.

Presented at the Third National Oil and Gas Power Meeting, State College, Pa., June 12 to 14, 1930, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

quality. The constants of design were determined and operating difficulties and shortcomings were noted.

At the conclusion of these tests it was decided that no available Diesel could be substituted for the established gasoline engine and meet the exacting service demands. Problems in combustion were not sufficiently solved to cope with the fuels which were desired for consumption. The general designs were unsuited to the environments of operation and were incapable of guaranteeing reliability under tractor-service conditions. If these Diesels could have been applied to the tractor, the tractor selling price would have increased 65 to 85 per cent. Maintenance costs in some cases were estimated to be higher than could be offset

FIG. 1 TRACTOR UNDER NATIVE OPERATION IN AFRICAN JUNGLE

FIG. 2 PLOWING SNOW IN FREEZING WEATHER WITH TRACTOR EQUIPMENT

by the fuel economy. It was therefore thought advisable to experiment with fuel systems and to organize a program of investigation for the development of an oil-burning engine of satisfactory combustion characteristics. Neumann puts it clearly when he states:

"The development which controls the high-speed prime mover today forces us to bring to the fore the dynamics of the combustion process."

The fuel system should permit the tractor Diesel to maintain its full rated load continuously with economic fuel consumption, and yet be sufficiently flexible to operate at idling speeds and varying loads without disturbing the combustion process or creating difficulties with it.

In achieving a satisfactory fuel system, the background of tractor-engine designing experience would then be available to encircle the fuel system in a suitable structure constrained by materials of proved character and selected heat treatments.

To carry out this program, a rugged engine of flexible design was chosen which would permit the installation of a variety of fuel systems. A test schedule was established which could evaluate each fuel system tested and form a basis of comparison for the ultimate judgment of the systems. Each fuel system was given preliminary trial runs to bring combustion efficiency to its highest value and to make combustion control as smooth as obtainable. Three distinct types of precombustion chamber

FIG. 3 TRACTOR HAULING ON A DUSTY ROAD

FIG. 4 USING TRACTORS FOR LOGGING OPERATIONS IN ROUGH COUNTRY

systems were tested, and three different methods of direct injection were applied to the test engine.

The first system, indicated in Table 1 as "A—Precombustion," utilized a variable injection-timing mechanism. The "B—Precombustion" chamber system was fitted with a variable cut-off control, while the "C—Precombustion" chamber system was fitted with controls on both injection timing and cut-off. The "D—Direct Injection" system was provided with an open-nozzle fuel system arranged with suitable turbulence. The "E—Direct Injection" system failed to function properly. The "F—Direct Injection" system employed a multiple-orifice constant-pressure fuel system. The schedule of the week's test run is briefly outlined as follows:

Full-Load Test From Monday, 10 A.M., Until Wednesday, 10 A.M. With the controls of the fuel system set for full-

load operation, the engine was permitted to run without further adjustment for the above-designated period. During this run data were obtained according to a printed schedule, and all variations and incidents relative to operation were noted and recorded.

No-Load Test From Wednesday, 10 A.M., Until Thursday, 10 A.M. The fuel controls were set to permit the engine to operate at no load and at approximate full speed. The control was not disturbed or adjusted until the termination of this test.

Valuable Load Test From Thursday, 10 A.M., Until Saturday, 10 A.M. During this run the controls were altered every half hour in the following manner:

1 Full load for one-half hour.
2 No load for one-half hour.
3 Full load for one-half hour.
4 One-half load for one-half hour.
5 No load for one-half hour.
6 One-half load for one-half hour.
7 Full load for one-half hour, and the cycle was repeated.

Overload Test From Saturday, 10 A.M., Until Saturday, 2 P.M. The controls for this test were set for operation at 10 per cent overload and 15 per cent overspeed.

Remarks

Before proceeding with any new experiment, the lubricating oil was flushed out and replaced with new oil. Samples of both the fuel and lubricating oil were taken in bottles on Monday morning prior to the first test and on Saturday afternoon upon completion of the test run for each experiment. The compression of each cylinder was obtained prior to and after each week's test run. The fuel consumption was obtained on Monday about 2 p.m., on Wednesday at 9 a.m., and on Saturday at 1 p.m. This schedule of tests indicated the practical performance of each type of fuel system.

Tables 1 and 2 show general results obtained on the various

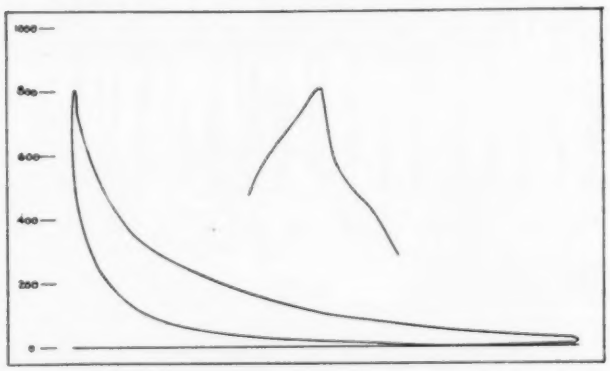

Fig. 8 Indicator Card With Fuel System A

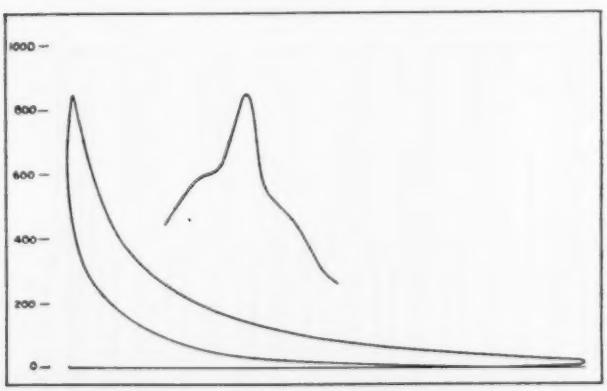

Fig. 9 Indicator Card With Fuel System B

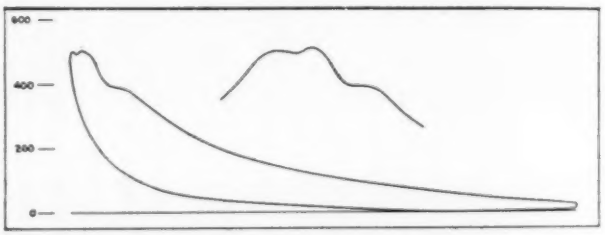

Fig. 10 Indicator Card With Fuel System C

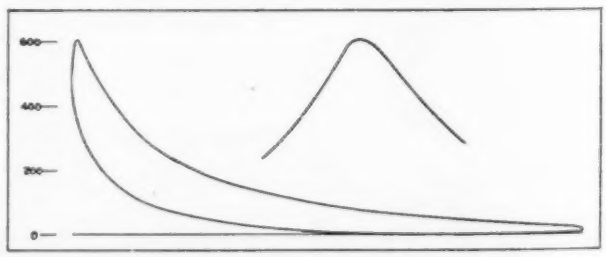

Fig. 11 Indicator Card With Fuel System D

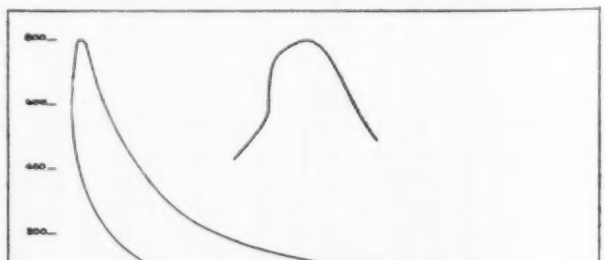

Fig. 12 Indicator Card With Fuel System F

fuel systems. The figure numbers listed in column 2, Table 1, refer to the indicator diagrams representative of loaded conditions. The 15-min. load readings taken during the week test run are graphically illustrated in Figs. 5, 6, and 7 for three of the fuel systems. These have been chosen as being representative of load variation during the runs. In Fig. 5 the full-load curve indicates considerable variation during the two days of operation. Under variable-load conditions it was impossible to reach full-load output at the throttle setting designated as

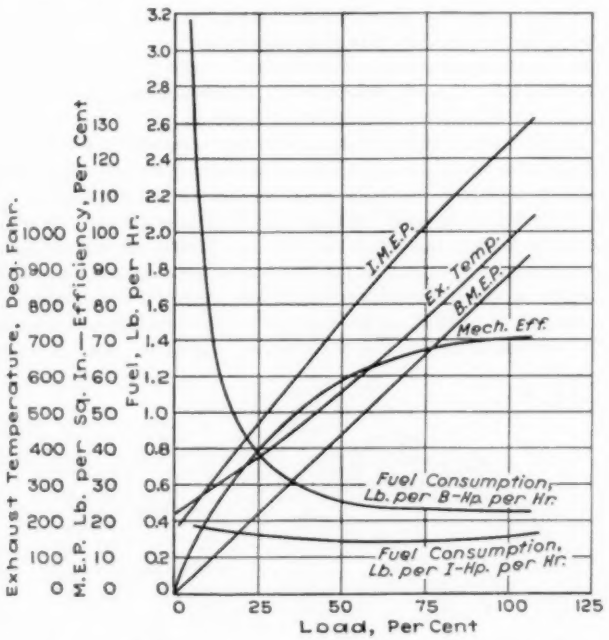

FIG. 13 PERFORMANCE CURVES WITH FUEL SYSTEM D

full load. Considerable variation is also seen in the power delivered at half-load throttle setting. The no-load curve shows fairly accurate metering of fuel. "No load" in each case was taken at full speed with the dynamometer absorbing approximately 2 hp.

Fig. 6 indicates a very uniform power output for designated throttle settings. The direct-injection system of the open-nozzle type developed a power-output curve as shown in Fig. 7. It was not deemed expedient to operate at the rated full load as combustion conditions were unsatisfactory and rough running was pronounced. It was therefore thought advisable to drop the full load so that the exhaust was fairly clean and operation fairly smooth. This procedure was followed in the case of each fuel system. It was considered imperative to determine full load at that value which would produce a clean exhaust at commercially desirable b.m.e.p. After uniform conditions were established in the preliminary tests prior to the week test runs, efforts were made to produce as smooth an operating condition as it was possible to obtain. To secure satisfactory operating quality in units which had manufacturing possibilities was the paramount ideal. Some combustion chambers are difficult to manufacture; other fuel systems require such extreme accuracy and delicate adjustments as to be prohibitive so far as manufacturing costs are concerned.

The results of these tests revealed the advantages and disadvantages of each fuel system in so far as concerns its ability or failure to meet the standards set up for oil-burning motive power by the Caterpillar Tractor Company. Some of the weaknesses may be summarized as follows:

1 Inability to maintain full load over extended periods of operation
2 Reduction of combustion efficiency at light loads
3 Disturbance of combustion process under variable-load operation
4 High maintenance cost
5 Tendency to produce rough running.

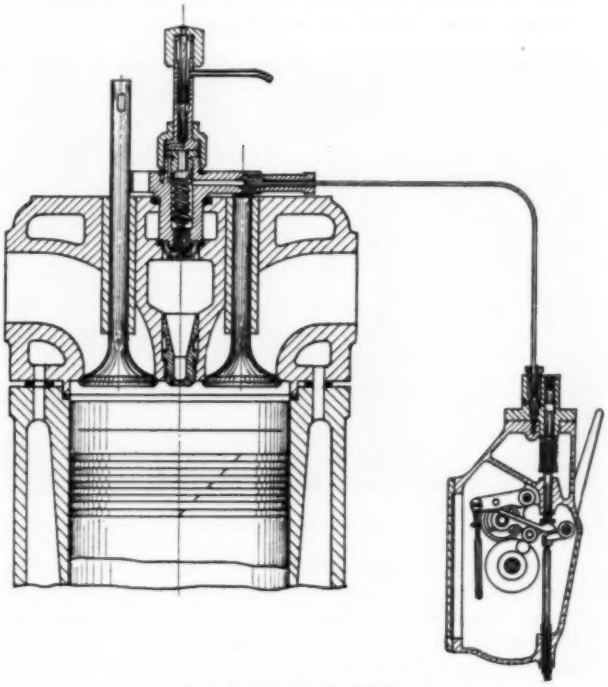

FIG. 14 A—PRECOMBUSTION

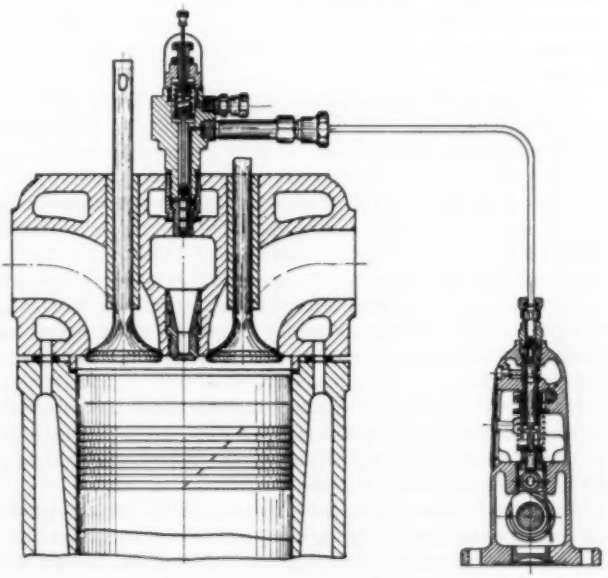

FIG. 15 B—PRECOMBUSTION

In spite of these undesirable qualities, some systems revealed sufficient promise to warrant the further development of the high-compression oil engine. A correlation of the desirable characteristics of all fuel systems indicated the path of development for a more efficient method of burning fuel, incorporating a control of practical operating quality.

It is generally understood that thermal efficiency and mean effective pressure rise as maximum pressures increase. In tractor work fuel consumption is not as pertinent as operating quality. It is therefore expedient to drop maximum pressures provided colorless exhaust and reasonable exhaust temperatures result. Experimental work has indicated a procedure for reducing maximum pressures and for controlling the increment of increase in pressure rise during the combustion period by the correlation of cam profiles with orifice design. Smooth operating

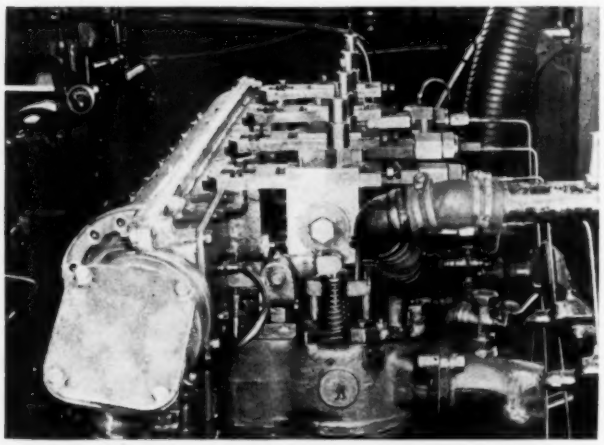

FIG. 16 C—PRECOMBUSTION

characteristics are intimately related to the rate of feed of atomized fuel, thus influencing the rate of combustion within the cylinder. The tests have also brought out inherent advantages in the precombustion chamber system. These can best be expressed by quoting Neumann from the *V.D.I.*, Sept. 8, 1928:

"In the high-speed Diesel engine the precombustion chamber process must be of advantage in the rapid heat transformation of the injected fuel by good distribution by means of high temperature and lively turbulence which may be obtained (in the engine) by simple means.

"The more rapid the formation of gas follows the inception of ignition through the breaking up of the molecule, the faster will be the ensuing combustion and of less consideration will be the heat loss to the surrounding media.

"The development of the precombustion-chamber engine to its present state took a long period of time. The beginning of its development goes back to the activities of Diesel. The top of this ascending line has not yet been reached as so often the work in actual practice advanced beyond the scientific knowledge. It is hoped, though, that the advancing knowledge into the working process of this engine will aid in giving a more efficient use of fuels in the future.

"In the use of heavy oils with high ignition points and with high carbon content, the precombustion-chamber engine is superior to the direct-injection engine; its surety of performance under severe service conditions is beyond question."

The ideal fuel system appears to contain the advantages of the common-rail and pump-injection methods of fuel injection.

Experimental work reflects the history of Diesel-engine fuel systems. The air-injection process has been in effect for many years, yet each size and type of engine requires test-stand alterations to produce the desired thermal results. Practically all solid-injection fuel systems have been developed by the "cut-and-try" method. If the high-speed engine is to enjoy manufacturing privileges, spray-research equipment is essential to guarantee uniformity of operating performance. Such factors as time distribution of spray, space distribution of spray, and pressure variation in oil lines and channels, require the use of measuring equipment for determining the control of the variables involved and also to cheapen manufacture. It is difficult to predetermine limits in finishes, tolerances, and channel courses and contours unless definite knowledge of the influence of these factors upon engine functioning is determined.

Burstall is credited with expressing the thought at the London World Power Conference that the physical and chemical questions of combustion must be solved through scientific work unaffected by commercial considerations. This statement is true and the oil-engine manufacturers laud the excellent work of Pennsylvania State College and Langley Field in spray research. The manufacturer, however, can apply only the fundamentals developed by these institutions to commercial practice by the intelligent measurement of functional values.

Combustion-chamber design must be influenced by the economics of manufacturing and the demands of service. The disposition of valves, the shape of piston crowns, and the contour of cylinder heads, should follow the dictates of scientific combustion-chamber design, but must yield in compromise to the pressure of practicality. Just how far this compromise should go to the benefit of economic construction, only research can decide.

Special emphasis has been given to the combustion process for Diesel-tractor service. Particular emphasis must also be

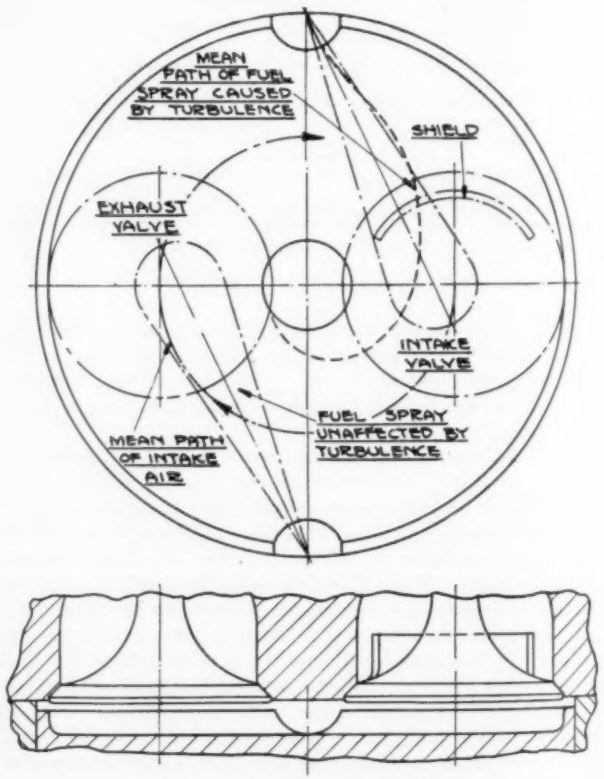

FIG. 17 D—DIRECT INJECTION

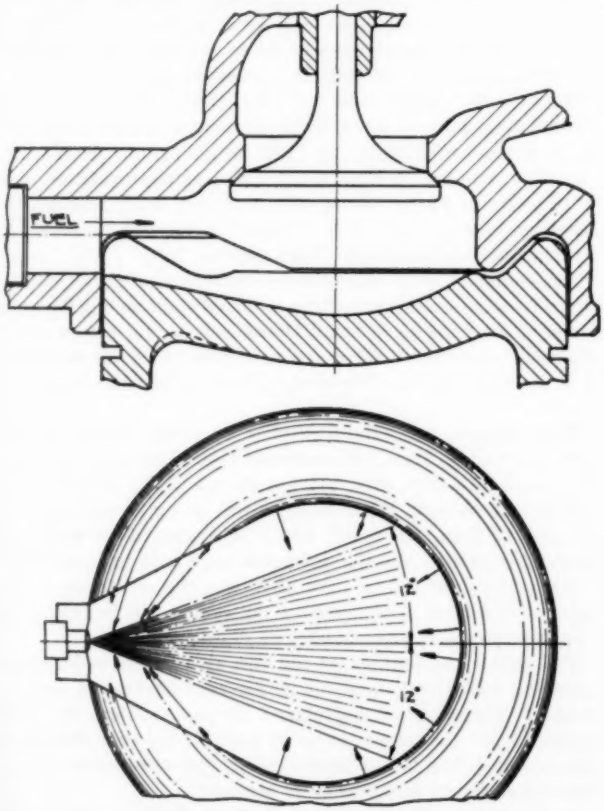
placed on the character of the design. The engine structure must have rugged strength to permit of continuous development of relatively high b.m.e.p. The total engine weight is governed by definite limits for traction equipment. The crankshaft and rotating masses must be free from severe torsional vibrations and be so balanced as to prevent structure vibrations under normal combustion processes.

In tractor-engine design, many problems are incurred in endeavoring to obtain dust exclusion and oil retention. Good

automotive practice is not sufficient to guarantee these conditions. In the gasoline type of tractor engine, special constructions are employed for magnetos, carburetors, and other accessories. The general design must permit of accessibility to vital parts and allow adjustments without risk of dirt contamination. Piping must be enclosed and control shafting and extensible parts must be protected from branches of trees and other outside agencies which might tend to tear off parts if unprotected. In the Diesel where complete enclosure is desirable, measures must be taken to prevent fuel contamination of the lubricating oil through the leakage of plungers, vents, etc.

Accessories are extremely important in tractor service inasmuch as precautionary methods of a strict character must be made to prevent dust from entering the engine structure and to minimize the amount of dust carried into the engine cylinders. Dust seals are therefore of vital importance, and all openings and through shafts must have packed seals under constant pressure. There is no more important part on the tractor than the air cleaner, for without it, the operation of the unit would fail in a very short time. Years of experience have been devoted to perfecting efficient air cleaners. In connection with the Diesel, the air cleaner presents an even greater problem. The relatively lower fuel-air ratio in the Diesel, as compared to the gasoline engine, requires every desirable means to increase the total volume of air available for combustion within the cylinders. Normally the fan and air cleaner consume 10 per cent of the engine power. The volumetric is reduced probably 2 per cent, and the best cleaners under severe operating conditions are about 90 per cent efficient in dust exclusion. The commercial necessity and the technical desirability of increasing the horsepower-weight ratio in marine Diesel engines has fostered the development of supercharging methods. Undoubtedly some commercial means for combining air-cleaner operating with supercharging methods will raise the b.m.e.p. without deleterious results. In the McLaren wheel-type of plowing-tackle tractor, superchargers are employed for Diesel engines for boosting the peak power under overload conditions. It is thus possible to obtain an increase in power of 35 per cent without increasing heat stresses or encountering valve difficulties. The urgent need for increased weight of air to support the combustion of more fuel, encourages the development of pressure-charging methods for air cleaning and cylinder filling



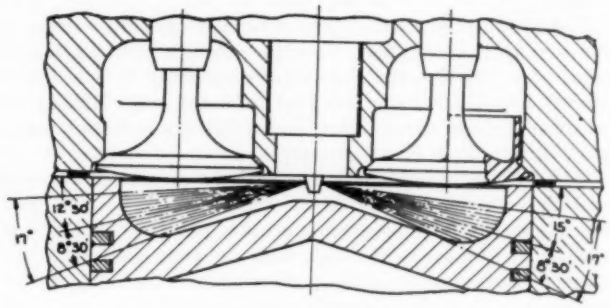


FIG. 18 E—DIRECT INJECTION

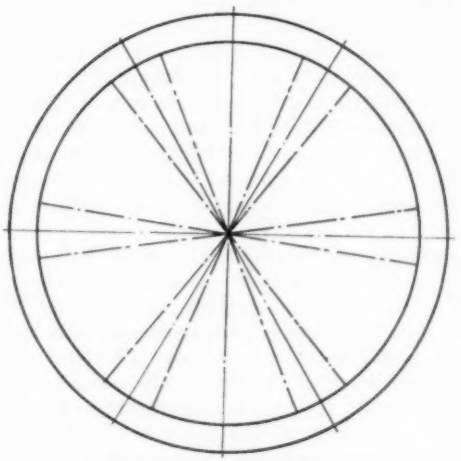

FIG. 19 F—DIRECT INJECTION

Fuel-oil filtering on mobile Diesel equipment urges investigation of fuels available at points of world distribution. Metal and cloth types of strainers each have their advantages, but have not been entirely effective in preventing foreign material from entering the fuel nozzles. The centrifuge has become an established institution on board ship and in power plants for the purification of fuel oil, but its application to tractor engines presents a difficult problem in the design of driving means to function under variable-speed operation. The opportunities for dust contamination when filling tanks in open fields and dusty country, or the risk of water absorption in moist weather, are ever present in tractor operation. Some simple method of eliminating these hazards from the engine fuel system must be developed.

The function of the lubricating-oil cleaner is sufficiently important to warrant careful study of this accessory. Under ordinary circumstances considerable surface is required in the filter-type of cleaner, as the impregnation of carbon in the minute openings reduces the effective area rapidly. Again, the centrifuge principle would be desirable, yet the added cost of such a unit may not show sufficient economy in lubricating-oil consumption to warrant its application on tractors. In the gasoline-engine tractor it is sometimes necessary, under severe service conditions, to change the lubricating oil once daily due to dirt contamination. A Diesel would not be expected to have the oil changed oftener.

Generally speaking, the Diesel can be considered as being more extravagant with lubricating oil. However, economies can be effected under clean-combustion operation. Fig. 13 indicates the influence of various fuel systems on lubricating oils. The most detrimental effect on lubricating oil is usually inflicted during variable-load and idling operation. Copper tubing for lubricating-oil conduits has also been found to accelerate the building up of acid numbers. Relatively large sump capacity permitting ample rest intervals to the oil is a helpful factor in maintaining good lubricating quality.

The problem of engine starters is rather complex and calls for continued development to reduce manufacturing cost. In most tractor service, electrical starters are out of the question as storage batteries will not stand up under the rough jostling and weaving of the tractor. Even electric-lighting systems are supplied directly from Bosch generators.

Air starting is not considered entirely satisfactory as dust and air-compressor valves do not work together harmoniously. Even in marine installations it is usual to run a suction line from the air compressor to the boat deck for pure clean air. In a tractor installation an auxiliary air compressor, gasoline engine-driven, together with air tanks, high-pressure lines, and valve controls, would be required.

A gasoline engine directly connected to the engine through a Bendix drive appears to be a far simpler arrangement. Furthermore, if starting is difficult due to cold weather or leaking plungers, considerable time is wasted waiting for the replenishment of storage tanks by the auxiliary air compressor in the air-starting system. In the direct-driven arrangement, continuous power is available to rotate the main engine at good starting speeds.

The hand-actuated impulse starter would warrant consideration if its cost could be reduced. Other methods of hand cranking have not proved dependable or given promise of reliability. The explosion of powder cartridges for starting impulse has been too erratic for unskilled labor to control. The chief objection to gasoline-engine starting methods is the necessity of carrying two grades of fuel. Its greatest asset, however, is positive starting. Improvement in starting methods is particularly desirable as a means toward reducing the cost of the starter equipment.

This paper has endeavored to present a general picture of the problems involved in the development of a Diesel engine for track-type tractors. A thorough solution of these problems has not yet been attained. Sufficient progress, however, has been made to direct the course of future development and to stimulate hope for the ultimate arrival at the desired goal.

The problems which have been discussed can also be applied to other traction equipment including excavators. However, it is believed that engineering scrutiny must be more severe in the case of track-type tractors.

In the development of the high-speed Diesel, the importance of good operating quality cannot be overemphasized. Commerical pressure demands designs capable of quantity production; the dictates of field service place a premium on simple, foolproof construction; reliability at all loads and speeds within the engine operating range is paramount; maintenance cost must be held to a minimum. The sum total of all of these factors is an equation in combustion research applied to practice.

A commercial Diesel-research organization must have its aspirations soaring in realms of scientific thought, but must also have its hand in intimate contact with economic necessity.

Discussion

A. M. Rothrock.[2] This paper is particularly noteworthy in that it gives actual experimental results and explains in detail the types of combustion chambers and injection systems used. To those who are conducting research on Diesel engines information of this type is important so that the progress may be known which is being made by the commercial organizations. There are two questions which the writer would like to ask. When using a combination common-rail and pump system, is a mechanically operated injection valve used? At what speeds will the engine idle satisfactorily when using this injection system? It is particularly interesting that the author found it necessary to use a combination common-rail and pump-injection system in order to obtain satisfactory idling characteristics. The writer also came to the conclusion that some such system is necessary to design an injection system whose operation is independent of engine speed.

Wm. K. Gregory.[3] The author states: "The relatively lower fuel-air ratio in the Diesel engine as compared to the gasoline engine requires every desirable means to increase the total volume of air available for combustion within the cylinders." Quoting further, "Normally the fan and air cleaner consume 10 per cent of the engine power. The volumetric is reduced probably 2 per cent and the best cleaners under severe operating conditions are about 90 per cent efficient in dust exclusion."

If the writer understands correctly, the air filter referred to reduces the volume of air available for combustion by 2 per cent. At an atmospheric pressure of 14.75 lb. per sq. in., the air filter would be required to have a resistance of approximately 8.28 in. of water to effect a 2 per cent reduction in air reaching the cylinders. This seems quite excessive in view of standard air-filter practice on stationary Diesel engines.

The company with which the writer is connected has concentrated its efforts on large stationary Diesel engines, but the problem of filtering the air on small Diesels suitable for use on mobile equipment does not involve any problems which are not found in large Diesel installations except greater dust concentration in the air.

The company's standard practice on large Diesel installations is to furnish filters with sufficient area so the actual pressure drop through a clean filter will not exceed 1/4 in. of water. As dust is accumulated, this resistance will go up as high as 1 in. of water in from four to six weeks' operation, after which the filter cell is cleaned, and the resistance drops back to 1/4 in. water.

When the filter cell is quite dirty and the resistance is 1 in. water, the volume of air entering the engine will be only 1/4 of 1 per cent less than when no filter at all is used.

The author also states that the best air cleaners under severe operating conditions are about 90 per cent efficient in dust exclusion. The filters manufactured by the American Air Filter Company are guaranteed to be at least 97 per cent efficient in dust removal, and actual tests in many instances have shown a cleaning efficiency in excess of 99 per cent.

In designing a filter for the protection of Diesel engines and air compressors there are three fundamental requirements:

1 The filter must have a high cleaning efficiency, at least 97 per cent
2 The initial resistance of a clean filter must be approximately 1/4 in. water, and must not exceed 3/8 in. water
3 The construction of the filter must be such that a large amount of dust can be accumulated by the time the resistance increases to as much as 1 in. of water.

What is meant by a large amount of dust may be indicated by the following test data:

A 20 in. by 20. in. by 4 in. filter cell having an initial resistance

[2] Associate Physicist, N.A.C.A. Langley Field, Va.

[3] Sales Manager, American Air Filter Co., Inc., Louisville, Ky.

of 1/4 in. water, will catch approximately 1 lb. of atmospheric dust before the resistance reaches 1 in. of water. It requires approximately 3/4 lb. of oil, or 0.85 pint, to saturate a pound of dust. It is therefore apparent that the oil-holding capacity of a filter has a definite bearing on its cleaning efficiency and dust accumulating capacity.

As mentioned previously, the company with which the writer is connected directs its attention primarily to large Diesel engines, gas engines, and air compressors, but several years ago a few contacts with manufacturers of mobile equipment were established which have led to the belief that most of them do not appreciate one fact emphasized by the author, who states: "There is no more important part on the tractor than the air cleaner, for without it the operation of the unit would fail in a very short time." To most manufacturers, however, when considering an air filter the first and most important consideration appears to be low cost; second, they want the filter to be light in weight and to occupy very little space; and third, they want a filter that will require little or no attention.

Cleaning efficiency, resistance to air flow, and dust accumulating capacity, regarded as prime requisites of a satisfactory filter, are placed in a position of secondary importance. During the past two or three years the importance of air filters has become more generally recognized, and in justice to the manufacturers their viewpoint has probably been changed.

There is no reason why a Diesel or gasoline engine installed on a tractor or excavator cannot be equipped with a filter which will not restrict the volume of air more than 1/4 of 1 per cent, and which will have a minimum cleaning efficiency of 97 per cent. Under severe dust conditions it may be necessary to clean a filter of this type as often as once per day, although in many types of service it should not be necessary to clean the filter oftener than once per week. The whole secret of efficient air cleaning and low resistance to air flow lies in providing a filter of ample size, and in view of the fact that it is an accessory which has an important bearing on the service rendered by the engine, the cost, weight, and maintenance required should be secondary considerations.

OGP-53-4

Heat Recovery From Internal-Combustion Engines

By THOS. CLARKSON,[1] LONDON, ENGLAND, AND WM. BRADFORD,[2] EDGE MOOR, DEL.

THOS. CLARKSON

Citing the heat losses of locomotives and steam turbines, the authors aver the internal-combustion engine the most efficient mechanism for converting heat into useful work; yet even in this, two-thirds of the heat is wasted in exhaust gases and in cylinder jackets. The need for further heat conservation is urgent. In considering the recovery of heat from exhaust gases of internal-combustion engines, the authors lay down seven basic conditions. Adding to these limitations the avoidance of back pressure and the provision of a simple way of decarbonizing the heating surface, the designing of the ideal waste-heat boiler is not a simple matter. The evolution of the "thimble tube" boiler after 30 years of experience is described.

WM. BRADFORD

HEAT being one of the most valuable commodities with which engineers have to deal, it is nothing less than tragic that so much of it is wasted and lost. For example, the ordinary steam locomotive wastes over 90 per cent of the B.t.u. which are released in its firebox. Modern steam-turbine plants, with high pressure, superheating, condensing, preheating the air, and improved feedwater heating, are much more efficient than the ordinary steam locomotive, and go far to equal in thermal efficiency the internal-combustion engine, which may be taken as the most efficient appliance for converting heat into useful work. Yet it has to be recognized that, even with internal combustion, about two-thirds of the heat is wasted —about one-third in exhaust gases and another third in the cylinder jackets; therefore the need for further heat conservation is urgent.

The heat carried away in the water from cylinder jackets is necessarily of a low order; as there is a practical limit to the temperature to which jacket water can be permitted to rise. The exhaust gases are at a considerably higher temperature (especially in the case of engines of the four-cycle type), and therefore the recovery of heat from exhaust gases presents greater possibilities. In some cases hot jacket water may be usefully employed as feed to supplement the heat recovered from exhaust gases.

In considering the question of heat recovery from exhaust gases of internal-combustion engines, the following basic conditions must be recognized:

1 The maximum temperatures available are too low to have useful radiant effect; therefore means had to be devised to utilize "convection" in the most effective manner, and to secure the most effective "intimacy" between hot gases and heating surface.

2 The most convenient form in which to distribute recovered heat is either as steam or as hot water; therefore the heat-recovery apparatus naturally takes the form either of a boiler or a heater.

3 A boiler or a heater to fulfil ideal conditions for this service should have *the maximum capacity for being neglected and forgotten.*

4 It should also be effective in muffling or silencing the exhaust.

5 It should have the faculty of being operated "amphibiously," by which is meant that it should be capable of operating without water, at times when heat recovery is not needed, and at the same time carry on its other useful function of silencing.

6 The ability to withstand sudden and violent changes of temperature with impunity is a desirable quality of robustness.

7 Smallness of size and weight are also important factors, especially on shipboard and in railroad service.

When to all of these conditions is added the avoidance of back pressure (especially with engines of the two-cycle type) and the provision of a simple and effective way of decarbonizing the heating surface, it will be recognized that the problem of designing an ideal waste-heat boiler for use with internal combustion engines has not been so simple a matter as might at first sight appear.

The boilers which have been used previously for waste-heat recovery have been of ordinary type; generally multi-tubular, or sometimes of the Scotch-marine type. It is not surprising, therefore, that the science of waste-heat recovery has not made

---

[1] Consulting Engineer. Mr. Clarkson commenced engineering apprenticeship in 1877. In 1885 won a first place in Whitworth Scholarships. In 1888 was graduated in metallurgy from the Royal School of Mines. Was then appointed lecturer in metallurgy at King's College, London, which appointment was resigned in 1890 to develop his inventions. In 1903 started the first Clarkson steam-bus service at Torquay in Devon, followed by services in London and elsewhere. In 1910 he founded the National Bus Company, which has continued in operation ever since and is now allied to the railroad groups. Mr. Clarkson is a Past-President of the Institution of Automobile Engineers and a Member of Council of the Newcomen Society.

[2] Director of Engineering, Edge Moor Iron Company. Mem. A.S.M.E. Mr. Bradford was graduated from the Engineering Department of the University of Wisconsin in 1904, remaining as instructor in experimental engineering for one year. Was with Henry L. Doherty & Co. in public-utility operating work at Denver, Col., and Lincoln, Neb., 1905 to 1910; chief electrical engineer, Laclede Gas Light Company, St. Louis, Mo., 1910 to 1917; general power-plant design and construction work, 1917 to 1920; joined Engineering Department of Edge Moor Iron Company, 1920. For the past three years Director of Engineering, in charge of engineering, production, and development.

Presented at the National Oil and Gas Power Meeting, University of Wisconsin, Madison, Wis., June 23–26, 1931, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

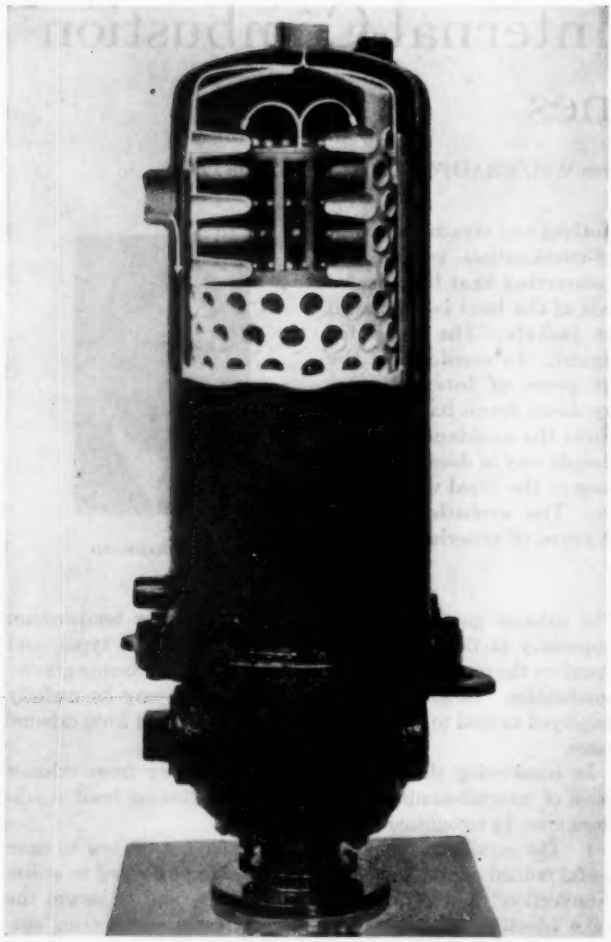

FIG. 1 "THIMBLE TUBE" HEATER, THE EXHAUST GASES ENTERING AND LEAVING AT THE BASE

more progress, as it is impossible to obtain the most effective results from such boilers. They do not function effectively as mufflers, neither do they lend themselves to decarbonizing of the heating surface by "burning off." They cannot be successfully operated "amphibiously," and they will not stand up against sudden changes of temperature.

Over 30 years' experience with boilers of many types and designs finally led to the evolution of the "thimble-tube" boiler, which in its primitive conception is an inversion of the "Porcupine" boiler. The tubes are tapered approximately radially, and in appearance resemble ordinary thimbles. Being secured at one end only, the thimbles are individually free to expand and contract, without causing strain upon the tube material or the joints. This explains the remarkable freedom, and in fact practical immunity, from tube trouble with the "thimble-tube" boiler.

The same principle of anchorage at only one end is adopted in the design of the complete boiler or heater, as in the case of individual tubes. In the case of return-flow boilers and heaters, only one end of the inner shell is fixed to the outer shell, the other end being free to expand or contract. This enables the heating surface to be decarbonized whenever necessary by "burning off," without loosening of tubes or straining of the boiler or heater.

The exhaust gases of some oil engines cause a deposit of oily soot to collect upon the heating surface of the boiler. Owing to the sticky nature of this deposit, it is not amenable to treatment by a soot blower, and the only really effective method for removal is by combustion or "burning off." In the case of four-cycle engines, with hotter exhaust gases, it usually suffices to empty the boiler of water and operate "dry" for awhile. In the case of two-cycle engines, it may also be necessary to ignite the deposit, which, as it contains about 66 per cent of oil, burns readily.

The "burning off" operation takes only a few minutes, and as soon as it is completed water can be at once readmitted without waiting for the boiler to cool; in fact, there need be no stoppage in the flow of exhaust gases over the "thimble tubes."

The most complete accessibility to the tube joints is afforded by removing the outer shell or by withdrawing the inner shell. Every square inch of heating surface is then open to direct vision. This is an important advantage also during construction. It has not been found necessary to weld the tubes in position; they are made a push-fit or a drive-fit into the tube plate, and they need only a slight amount of rolling. At the same time the open end is flared or belled to insure against the possibility of a tube being pushed through the tube plate by pressure and to give a stream-line effect to the flow of water and steam.

A few words may be devoted to the question of how circulation takes place within the "thimble tubes," as it is obvious that, with one end of the tube closed, the water and steam cannot circulate in a normal manner. Observations with glass "thimble tubes" have shown that when heat is applied to the outside of a "thimble tube" containing cold water, the water in contact with the heating surface rises vertically and displaces the water in the upper part of the tube, which is pushed out of the tube into the

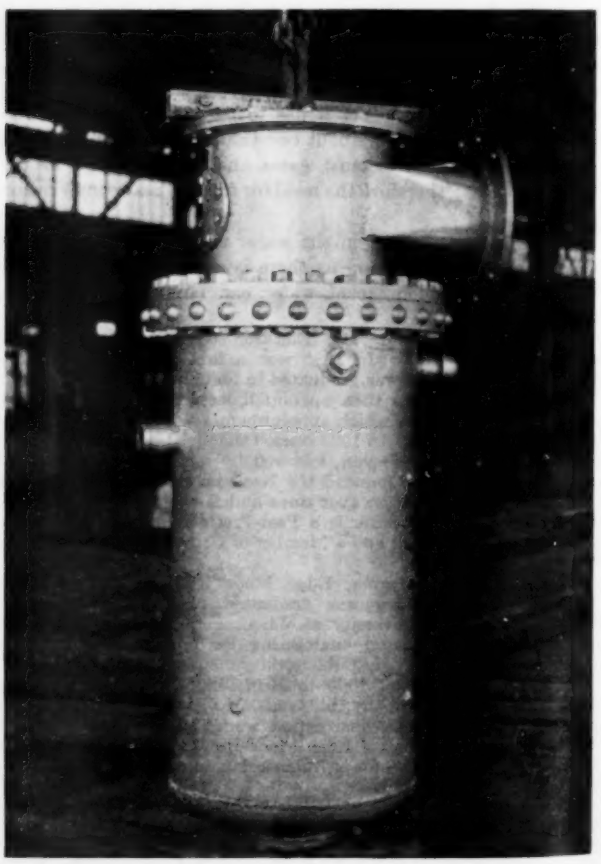

FIG. 2 "THIMBLE TUBE" HEATER INVERTED, WITH CONNECTIONS AT THE TOP

annular water space between the inner and outer shells. Another stratum of water enters the tube at the lower level, and in turn is heated, rises, and returns to the annular water space. This "convection" circulation proceeds continuously until the water reaches boiling point, when, instead of "convection" circulation, there is a copious streaming of steam bubbles from the heating surface out of the tube. When the tubes are strongly heated, this ebullition is so intense as to prevent more water entering the tube until the action has abated somewhat. The water then comes in with a rush, completely filling the tube like a water hammer, when the ebullition recommences. This pulsating action proceeds with a frequency depending upon the intensity of firing, and is helpful in preventing the formation and deposit of scale within the tubes.

The alternate rows of tubes are staggered so as to secure effective turbulence and impingement of the hot gases upon the heating surface, thus preventing the formation of inert films. The spacing of the tubes is calculated to give suitable mass velocity without causing back pressure on the engine.

Back pressure appears to be a source of anxiety to some engine builders, especially in the case of engines of the two-cycle type. It is important, therefore, to show that with a properly designed

A question of some importance in connection with the use of waste-heat boilers is their effect upon the efficiency of the engine. There is some divergence of opinion on this point. On the one hand, the view is held that the introduction of the boiler in the exhaust pipe must increase the back pressure and adversely affect the efficiency; on the other hand, cases have been recorded where a definite improvement in the efficiency has resulted from the introduction of the boiler. To investigate this point two tests were carried out—first, with the boiler in use, and then with the boiler removed and a plain exhaust pipe inserted in its place. The two tests were carried out on the same day, under identical conditions of load, speed, etc. It was found that there was no measurable difference in the consumption of gas, but that the air consumption was greater by some 1 1/2 per cent when the boiler was in use than when a plain exhaust pipe was substituted. This showed at once that if any back pressure was caused it did not continue till the end of the exhaust stroke—the really vital point. On the contrary, it indicated the existence of a negative pressure over that portion of the cycle where the opening of the admission valve overlaps that of the exhaust. Light spring diagrams show this effect in a very striking manner. The fluctuations in the pressure during the exhaust stroke are the result of vibrations in the column of gases in the exhaust pipe, and the frequency of these vibrations is such

NOTE: The boiler was connected to the engine by two exhaust pipes, each about 7 ft. long. In each pipe there were two right-angle bends. The pipes were not lagged.

waste-heat boiler there is no detrimental back pressure. This point was established several years ago in the following manner: A new engine of two-cycle type, 84–90 hp. was placed on the test bed and was run for several days against the dynamometer, with the usual muffler and exhaust-pipe connection, but without a waste-heat boiler. After the engine had been properly "run in" and constant readings were obtained for fuel consumption in relation to horsepower developed, a "thimble tube" heater was fitted close to the engine, and a fresh series of tests was made. The results proved that, far from causing any loss in efficiency, the same horsepower was developed with 3 per cent less fuel consumption. This result is explained by the sudden cooling of the exhaust gases in passing through the waste-heat boiler, which was naturally accompanied by a corresponding reduction in the volume of the exhaust gases. In other words, the boiler acted to some extent as a condenser, and actually facilitated the escape of the exhaust gases.

Careful investigations on this point have also been made by Prof. Gilbert Cook at the London University Engineering Laboratories, where several "thimble tube" boilers are installed. The results are best given in Dr. Cook's own words:

that the pressure happens to be positive at the end of the stroke, at the time when both valves are open, thus retarding the admission of the new charge. The effect of the boiler is to increase the capacity of the exhaust system, resulting in a lower frequency of the vibrations, so that in this particular case the pressure is negative at the end of the exhaust stroke. This condition is specially favorable for good scavenging. In a gas engine, where the fuel is already mixed with the incoming air, such a condition might not necessarily result in better efficiency, as the improved conditions of combustion might be offset by the passage of some of the fuel direct to the exhaust. That, in the opinion of the writer, is what has happened in the present case—an increase in air consumption without any appreciable effect on the efficiency. It is readily conceivable, however, that in an oil engine with fuel injection a condition such as this would entail a distinctly improved efficiency, and in those cases where such an improvement has actually been observed it is probable that the cause will be found to be similar. The writer is not prepared to say that such improvement must necessarily follow the installation of the boiler. The same effect might very well be produced either by a lengthening or a shortening of the exhaust pipe; there can be no doubt that small changes in the exhaust system have a much greater effect upon the performance of the engine than is generally recognized. It can, however, be definitely stated that there is no evidence of any sustained back pressure being caused by the boiler.

From the point of view of heat recovery it is obviously desirable not to water-cool the exhaust pipes or manifolds, just as skimmed milk is not the best for making butter. There has been a great lack of standardization among different makers of engines in the diameters of exhaust pipes in relation to the horsepower of engines. As examples of this may be cited the use of a 6-in. bore exhaust pipe for an engine of 60 hp., whereas another engine maker will use the same size of exhaust for 600 hp. The size of exhaust is greater in engines of the two-cycle type, and is naturally governed by the number of cylinders as well as the horsepower of engine. As a general rule the size of exhaust should be kept as small as possible, consistent with effective scavenging. This is facilitated by the use of multi-cylinder engines which have a more continuous exhaust, and which therefore can have a greater horsepower per square inch of exhaust-pipe area. The explanation why it is possible to discharge hot gases through an empty "thimble tube" boiler without injuring it is found in the fact that the gas temperature never reaches a point sufficiently high to burn the tubes and that there is complete freedom for expansion. The maximum temperature usually met with is in the neighborhood of 700 deg. fahr., although there are records of tests giving exhaust-gas temperatures of over 1000 deg. The usual temperature of gases from engines of the four-stroke type is from 600 to 650 deg. fahr. This of course depends upon whether the exhaust manifold of the engine is "dry" or "water-cooled." In engines of the two-stroke type the exhaust gases rarely exceed 500 deg. fahr.

There is, of course, a practical limit beyond which it is not desirable that the gases should be cooled in a waste heat boiler, in order to avoid condensation, particularly of the sulphurous contents, which might cause corrosion of the heating surface. As a general rule 300 deg. fahr. may be taken as the practical limit beyond which the gases should not be cooled.

The quantity of thermal units recoverable from the exhaust gases of an internal-combustion engine may be readily estimated by the simple formula, B.hp. $\times$ C $\times$ $D/4$, C being a constant (in the case of four-cycle engines, 12, and in the case of two-cycle engines, 20) and D being the drop in temperatures of the gases.

More heat can of course be recovered in the form of hot water than in the form of steam, as it is obvious that when generating steam the temperature of the gases leaving the boiler must be considerably above boiler temperature. The difference is usually not less than 50 deg., so that in the case of a boiler generating steam at 100 lb. per sq. in. the final temperature of exhaust gases could not be much less than 400 deg. fahr. If, on the other hand, hot water is to be produced, say up to a temperature of 200 deg. fahr., the gases could easily be cooled another

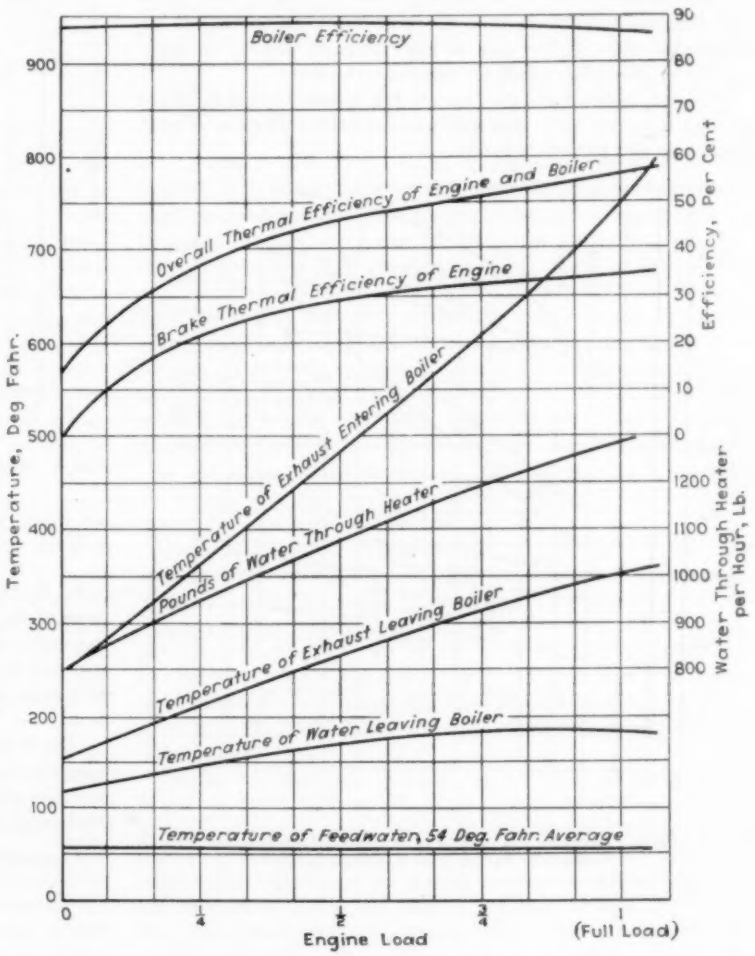

FIG. 6 CHART OF AVERAGE EFFICIENCIES AND TEMPERATURES OF FOUR-CYCLE MECHANICAL-INJECTION DIESEL ENGINE AND NELSECO CLARKSON WASTE-HEAT BOILER

100 deg., which, in the case of a two-stroke engine, may represent an increase of 100 per cent in the quantity of heat recovered.

When considering the production of hot water, advantage can usually be taken of the contra-flow principle; that is, bringing the exhaust gases in at the top of the heater where they come in contact with the hottest water, and causing them to travel in a downward direction over the heating surface, so that they ultimately come into contact with the coolest water.

The general construction and arrangement of a "thimble tube" heater are illustrated in Fig. 1, which is a heater of the erect type, the exhaust gases entering and leaving at the base of the heater. In some installations it is more convenient to invert the heater and have the inlet and outlet connections at the top. This type is shown in Fig. 2.

In large marine installations the "through" type is extensively

used. In this type the exhaust gases enter at the base and leave at the top, thus conforming to the general direction of flow of the exhaust gases upward from the engine in the hold of the vessel, to the top deck, where the funnel is located. An illustration of the "through" type is shown in Fig. 3, which is a vertical section of one of the four main waste-heat boilers dealing with the exhaust gases from 20,000-hp. Diesel engines of the motor-vessel *Britannic*.

The largest internal-combustion engines are to be found in marine installations. It is therefore not surprising that there has hitherto been more heat recovery practiced in marine installations than in the case of land services, which, however, appear to offer a large field for useful development.

Tables 1, 2, and 3 and the chart in Fig. 6 show typical examples of heat-recovery tests with internal-combustion engines of both four-cycle and two-cycle types.

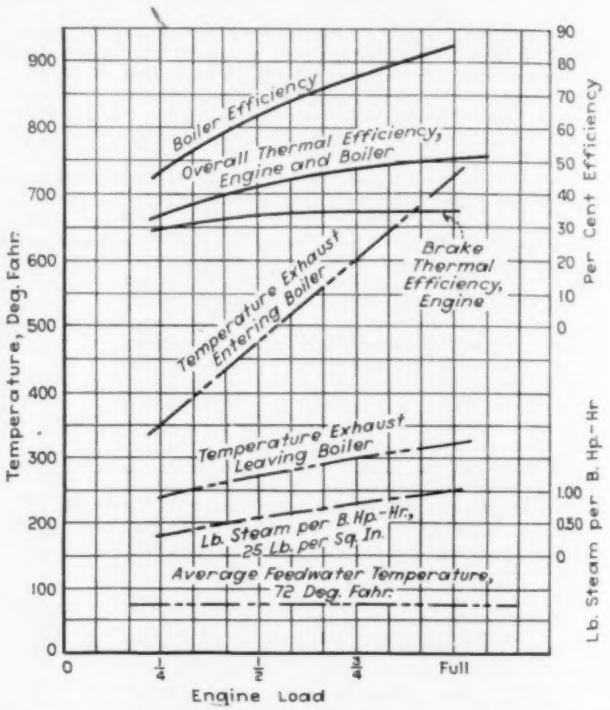

FIG. 8 SHOP TESTS OF EXHAUST-GAS STEAM BOILER, ENGINE UNDER VARYING SPEED AND VARYING LOAD

Discussion

L. B. DOANE.[3] As a supplement to the chart on the fifth page of the paper (Fig. 6), which gives results obtained by heating water with the exhaust gases from a Diesel engine, the writer presents two additional charts that give data obtained by using this same heater as a steam generator under exhaust-gas operation.

One of these charts, Fig. 7, shows results obtained when running the engine under constant-speed and varying-load conditions and the other, Fig. 8, shows results when operating the engine with both varying speed and load.

Dispersion of Sprays in Solid-Injection Oil Engines

By KALMAN J. De JUHASZ,[1] STATE COLLEGE, PA.

In investigating the problem of how to improve atomization and dispersion in the solid-injection oil engine, the knowledge of the mechanism of spray formation was found to be scant. In the researches covered by this paper, it was not attempted to develop a spray theory. A few experiments were made for the purpose of clearing up which physical forces do or do not participate in the atomization and distribution process. A large number of charts have been made representing sprays under various conditions, these seeming to point to the following general conclusions: Dispersion becomes more even when injection pressure is increased, when the oil viscosity is decreased, and when the air density is increased; the cone angle increases with increasing oil pressure, increasing air density, and decreasing viscosity of oil; a larger percentage of oil reaches a given distance in a spray having a slenderer spray cone; no definite influence of orifice dimensions was noticeable in using cylindrical orifices of the dimensions employed in the tests discussed.

IN THE dark ages of oppression Machiavelli propounded the sinister doctrine of "Divide and rule" as the most effective policy for obtaining and holding control over a body of people. In this more enlightened and civilized era, in the peaceful art of internal-combustion engineering the same principle can be usefully applied to the fuel charge, and thereby an effective control over the combustion be obtained. Trying to put this precept into practice constitutes one of the main problems of the solid-injection oil engine today.

In an oil engine the divisions must be twofold: First, the injected fuel must be divided into sufficiently small particles. Thereby, a large surface is made available upon which the chemical reaction with the oxygen of the combustion air can take place. This process, called atomization, is the essential prerequisite of complete and rapid burning. Second, these particles must be mixed with, and be distributed evenly in, the combustion air in order that the combustion take place without waste of fuel and at high loads, also without waste of air. This process, called dispersion, is a fundamental requirement for low fuel consumption and high mean effective pressure.

These latter-named performance characteristics are highly desirable for all, and a necessity for many applications of an internal-combustion engine.

As to the first of these, low fuel consumption, the solid-injection oil engine is superior to its rivals, the carburetor engine and the air-injection Diesel engine. With respect to the second characteristic, high mean effective pressure, however, it lags sadly behind them. There is no basic reason for this disadvantage. Owing to the high thermal efficiency of its cycle and the absence of power-consuming accessories, the solid-injection oil engine possesses an inherent potentiality for high mean effective pressure. The reason for this deficiency is the lack of satisfactory combustion control, which offsets the advantage of the superior engine cycle by necessitating the use of a large percentage of excess air. It may be said that the future progress of the solid-injection engine and its entrance into new fields of application depend to a large degree on the progress in eliminating this deficiency by better combustion control, with which the processes of atomization and dispersion are closely connected.

Both these processes absorb energy. In the atomization process, by increasing the total surface of the liquid, work has to be expended to overcome surface tension. In the dispersion process, over and above the work necessary to bring a volume of oil into a space under pressure, work has to be expended against air resistance when the particles penetrate into the dense combustion air. The turbulence necessary for mixing involves overcoming the friction of the air with the chamber walls and the viscosity forces of the air motion. It is of interest to compare the energy expended for these purposes in the air-injection process and in the solid-injection process.

In the air-injection process this energy is equivalent to 6 to 14 m-kg. per gram of oil, depending on the pressure of the injecting air (900 to 1000 lb. per sq. in.) and on the weight ratio of injection air and oil (usually 1 to 2). Incidentally, this energy is equal to 0.5 to 1.2 per cent of the work derived from the oil in the engine. This comparatively large amount of energy brings about a violent turbulence and intimate mixing of the fuel particles with the air, and consequently a high degree of utilization of both. (See Appendix 1.)

In the solid-injection process the energy is contained solely in the oil due to its pressure. Storing in a gram of oil the same amount of energy as is used in the air-injection process would involve pressures of 8000 to 18,000 lb. per sq. in. There are serious objections to the use of such pressures in engineering practice on account of the high stresses and ensuing wear and tear in the pump mechanism and nozzle parts. Even if applied, the result would not be the same as with air injection owing to the different nature of the atomization process. In actually built engines much lower oil pressures (3000 to 5000 lb. per sq. in.) are used, corresponding to 2 to 4 m-kg. energy per gram of oil. This energy is equivalent to 0.2 to 0.3 per cent of the useful work derived from the same quantity of oil. There is even a tendency to use still lower injection pressures, which would be of advantage for the ease of manufacture of the pump and nozzle parts and for their useful life.

In theory, at least, there is no basic obstacle in the way of obtaining a high degree of atomization with only little expenditure of energy. The atomization energy is equivalent to the product of surface tension and total surface. The surface tension is of the order of magnitude of 0.003 kg. per m. for oils which come into consideration here. The total surface is the sum of the surfaces of the individual droplets. Imagine a quantity of oil as a compact sphere of R_1 radius and A_1 surface area. When this sphere is broken up into droplets of r_n radius, the total surface is enlarged in inverse ratio to that of the respective radii:

Presented at the National Oil and Gas Power Meeting, Madison, Wis., June 23 to 26, 1931, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

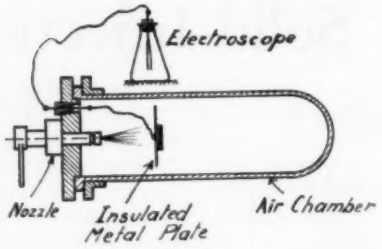

FIG. 1

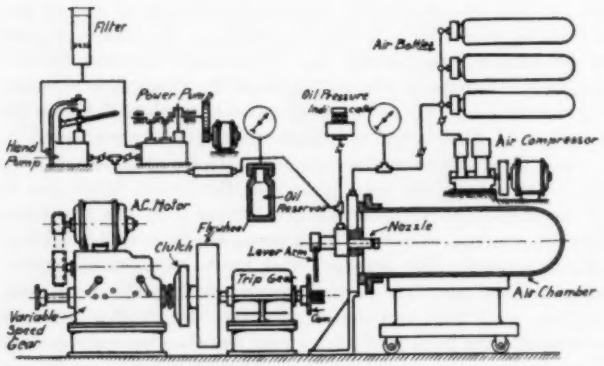

FIG. 2 SCHEMATIC ARRANGEMENT OF OIL-SPRAY APPARATUS

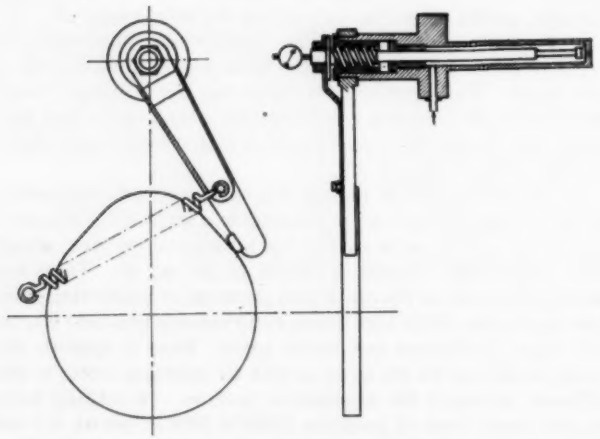

FIG. 3 SPRAY-VALVE MECHANISM

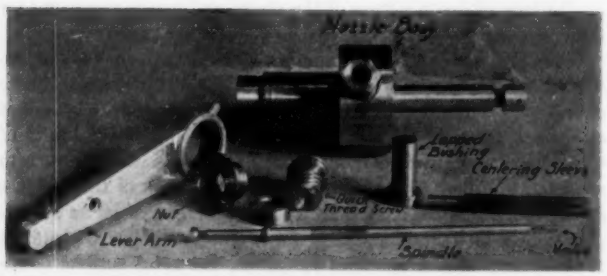

FIG. 4 COMPONENT PARTS OF THE INJECTION NOZZLE

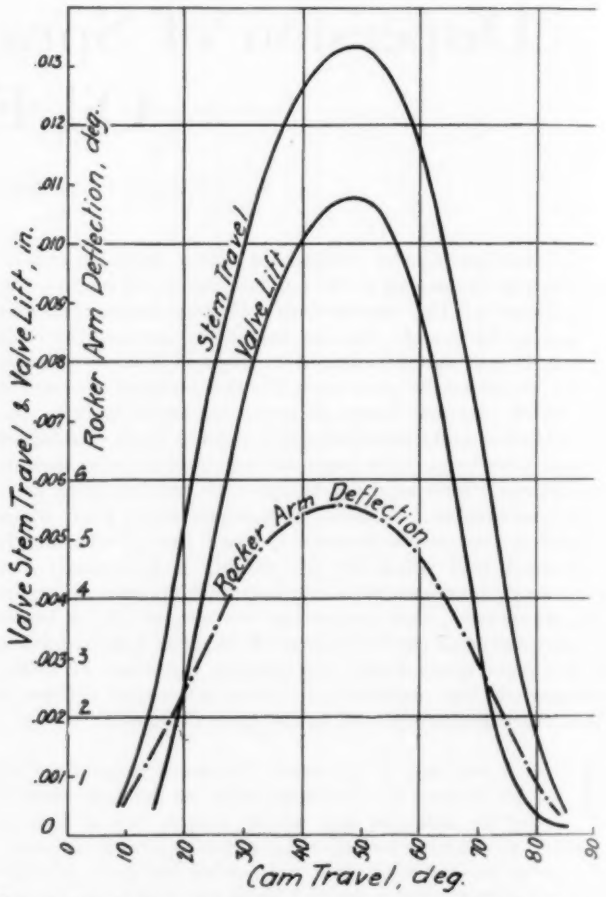

FIG. 5 CHARACTERISTIC CURVES OF CONSTANT-PRESSURE INJECTION NOZZLES

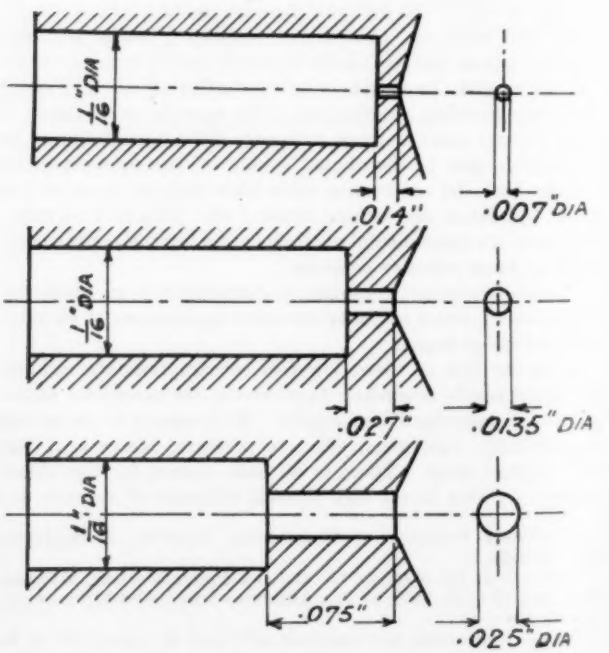

FIG. 6 ORIFICES USED IN CONSTANT-PRESSURE INJECTION EXPERIMENTS

$$\frac{A_n}{A_1} = \frac{R_1}{r_n}$$

The enlarged area A_n corresponds to the surface of one sphere, which may be called "equivalent bubble," having a radius R_n which can be expressed:

$$R_n = R_1 \sqrt{\frac{A_n}{A_1}} = R_1 \sqrt{\frac{R_1}{r_n}}$$

Putting it in another way, the atomization results in a surface increase equivalent to coating a large sphere of R_n radius with the original quantity of oil in a thickness of $r_n/3$. (See Appendix 2.)

On Fig. 17, in Appendix 2, these relationships are graphically

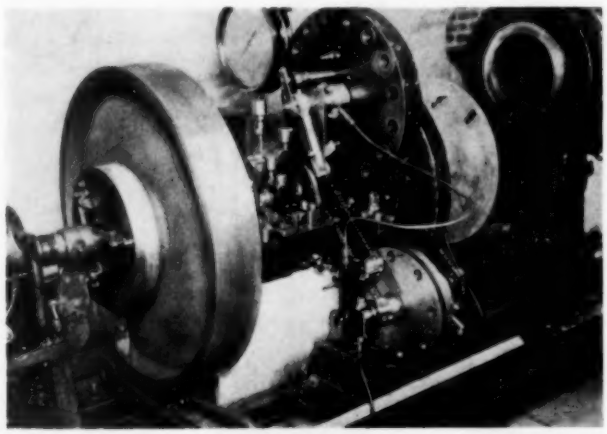

FIG. 7 ARRANGEMENT OF PUMP INJECTION SYSTEM

shown for droplet sizes comparable to those in solid-injection practice, and the surface-energy values corresponding to 1 gram of oil are given in the table therewith. Such simple calculations show that to atomize 1 gram of oil into droplets of 0.0002 cm. radius, which is an atomization comparable to that obtainable with air injection, only 0.005 m-kg. work is necessary. It is quite conceivable, however, that in some intermediary stage of the drop formation the liquid has a greater energy content than its final stage, similar to an elastic cord which is stretched until broken. Nevertheless, it seems safe to assume that the energy required for atomization is only a minute fraction of the total energy of injection, the greater part of which is expanded in the process of dispersion and turbulence and finally is converted into heat.

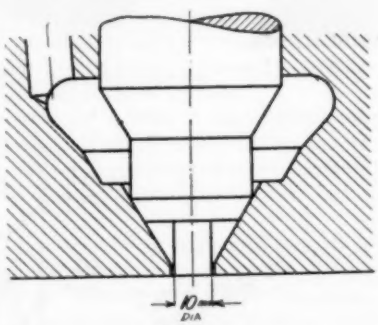

FIG. 8

In investigating the problem of how to improve the atomization and dispersion, a knowedge of the mechanism of spray formation would be of considerable help. It should be stated, however, that knowledge in this field is very scant, though there are a few theories that may provide a background for the understanding of spray phenomena. The breaking up of a liquid column issuing from an orifice under a pressure head has engaged the attention

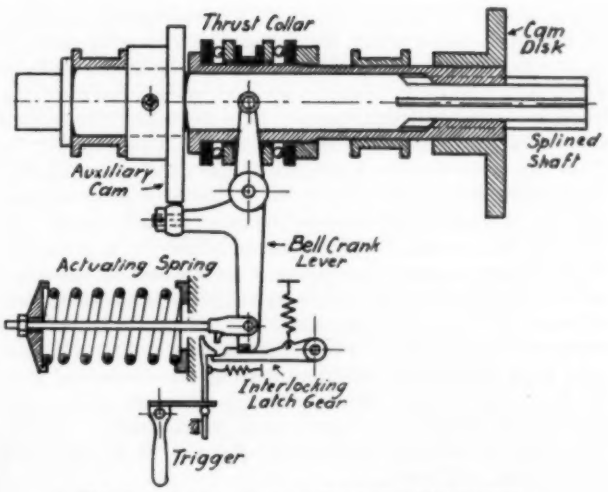

FIG. 9 ARRANGEMENT OF SELECTOR MECHANISM

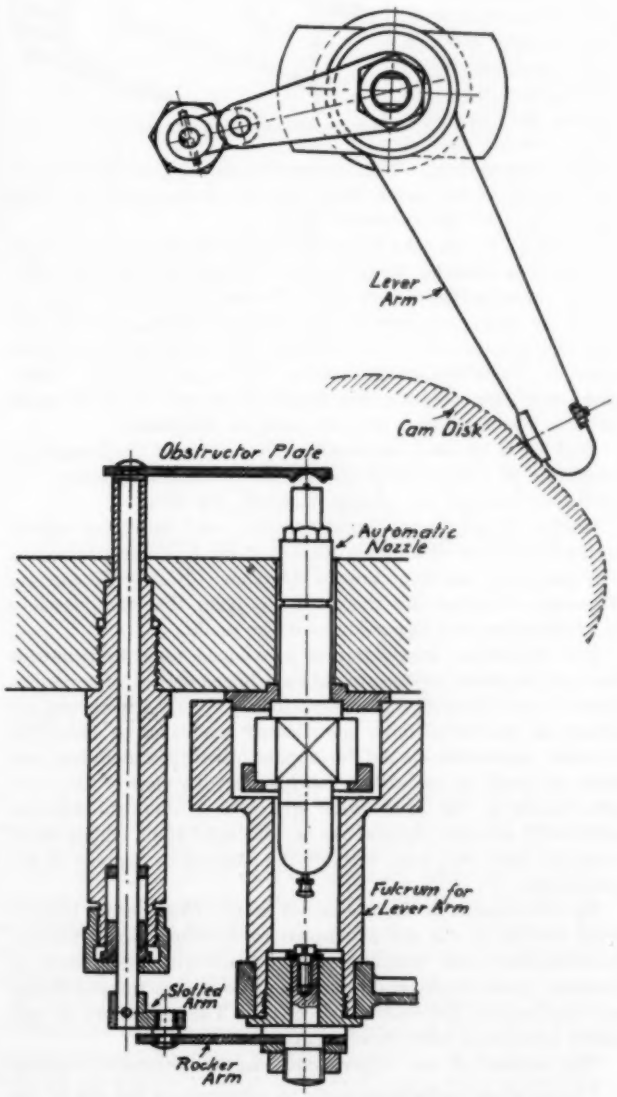

FIG. 10 METHOD OF ACTUATING OBSTRUCTOR PLATE

of numerous investigators. Plateau (1)[2] investigated the physical conditions under which the collapse of a round cylindrical liquid column takes place. He found that the column is unstable if its length exceeds its circumference and will collapse under the influence of any small disturbance. Lord Rayleigh (1) calculated the rate of collapse. More recently R. A. Castleman, Jr., (1) of the Bureau of Standards, amplified these theories and applied them specifically to the atomization of liquids in an air stream, under conditions similar to those occurring in carburetors. He describes the process of atomization as follows: "A portion of the large mass is caught up (say at a point where its surface is ruffed) by the air stream, and being anchored at the other end, is drawn out into a fine ligament. This ligament is quickly cut off by the rapid growth of a dent in its surface, and the detached mass, being quite small, is swiftly drawn up into a spherical drop. The higher the air speed, the finer the ligaments, the shorter their lives, and the smaller the drops formed, within limits." Castleman refers to the solid injection as follows: "It is found that when liquid is forced under very high pressure into still air it is finely atomized. As the high injection pressure merely gives a high initial velocity to the injected liquid, it is seen that this case also is similar to air-stream atomization. The fast-moving liquid loses ligaments to the still air in the same way that the fast-moving air drags ligaments from the quiescent liquid."

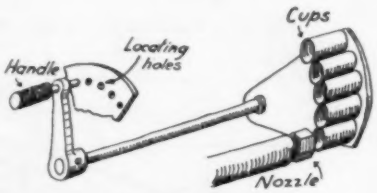

FIG. 11 DISCHARGE CUPS

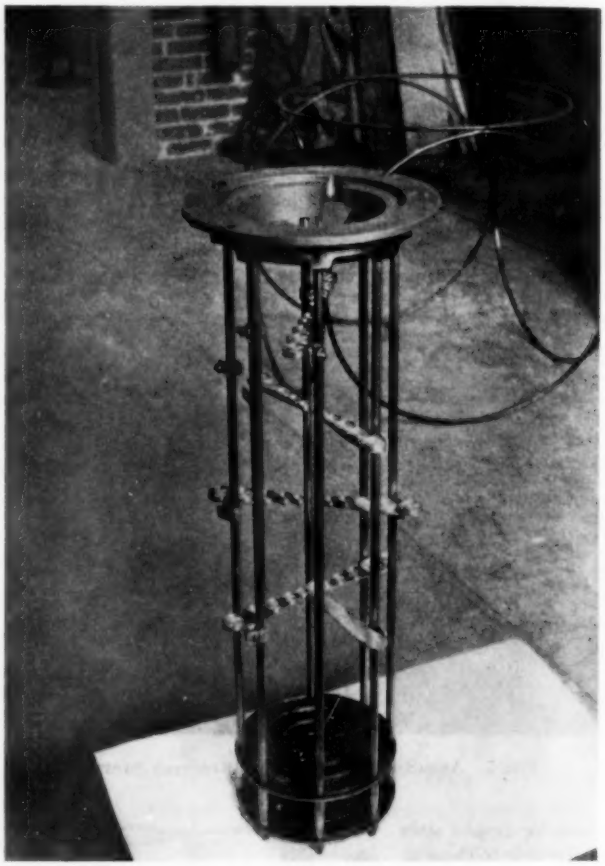
Triebnigg (2) attacks the problem of atomization by solid injection from a similar point of view. In his very thorough theoretical investigation of this subject he assumes that the breaking up of the spray is caused by the combined action upon the free end of the liquid jet of two forces: air resistance and surface tension. Upon this assumption he builds up an elaborate theory from which he computes the droplet sizes and jet shape under various liquid-pressure and air-pressure conditions.

Bird (3) in his analysis considers the energy of the droplets as consisting of 1 (*a*) surface energy, (*b*) translational energy, (*c*) rotational energy, (*d*) circulation inside the drop.



Kuehn (4) attributes the atomization and dispersion chiefly to the turbulence and vortex motion of the liquid in the nozzle. Thiemann (5) also leans toward this view. Neither Kuehn nor Thiemann develops this theory to the point that computations of atomization and dispersion could be made.

The theoretical investigations mentioned refer to primitive forms of jet under low pressure or have been evolved, of necessity, under drastic simplifying assumptions. For oil-engine use the sprays are produced under complicated conditions to which the theories mentioned cannot be applied directly and indeed are likely to result in misleading conclusions. In view of the complex nature of the oil-injection sprays, it is doubtful whether sufficiently accurate theories can be developed at all, which would stand on their own feet, without the continuous support of experiments.

For this reason in the researches at the Engineering Experiment Station it was not attempted to develop a spray theory. Nevertheless, a few experiments were made with the purpose of clearing up which physical forces do or do not participate in the atomization and distribution processes. The results are of sufficient interest to merit brief mention.

The purpose of one experiment was to determine whether atomization is due to the friction of jet with the air. Sprays were injected into an evacuated chamber, the air pressure being one-fiftieth atmospheric pressure (about 0.6 in. Hg. abs.), and thereby the air resistance was reduced to a very low value. In spite of this it was found that the spray was atomized and dispersed to approximately the same extent as in air of atmospheric

[2] Numbers in parantheses apply to references at the end of the paper.

FIG. 12 DISPERSION RACK

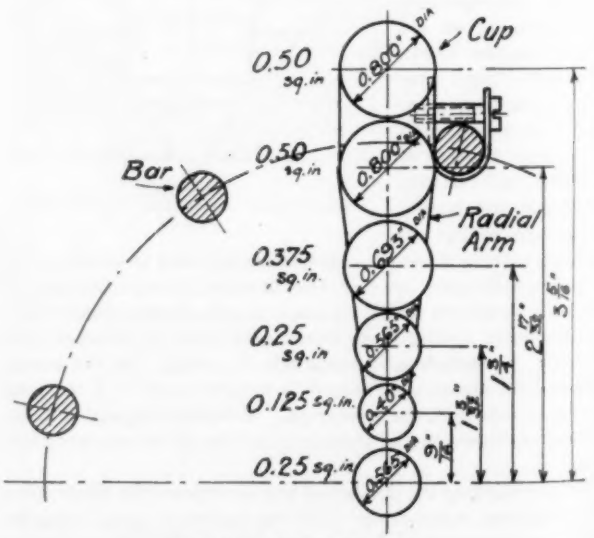


FIG. 13 DISPERSION RACK

density. Further increasing air density to multiples of the atmospheric density, however, had the effect of widening the spray angle, making the distribution pattern more even and reducing the penetration. This result seems to be strong evidence against the supposition that the atomization and dispersion are due solely to air-friction forces.

Another experiment was made to determine whether the oil particles, during their passage through the nozzle, become charged with static electricity owing to friction, which may contribute to their dispersion as a consequence of electric repulsion. The spray was injected against an insulated metal plate connected to an electroscope as shown on Fig. 1. The indication was entirely negative. On no occasion could the existence of static charge be demonstrated.

These evidences lend support to the view that (under the conditions of oil-engine injection) the liquid emerges from the nozzle in an already atomized, or at least disgregated state, that it already possesses the ability to disperse, and therefore that in the atomization and dispersion process the flow phenomena in the nozzle are the main influencing factors.

Experiments Relating to Spray Dispersion

Lacking a suitable theory for the explanation of spray phenomena, recourse has to be taken to experimental methods in order to determine those spray characteristics that are of interest from the engine-performance point of view. Even though the law of it is as yet undiscovered, yet spray formation is none the less a process obeying physical laws, and as a consequence the sprays assume the same properties under similar conditions, i.e., with the same values of the governing factors. The spray is formed by forcing the required quantity of fuel through a nozzle into the air contained in the combustion air. The characteristics of the spray, and among these its dispersion in space, depend therefore on three sets of factors, as follows:

(1) Fuel factors, comprising oil pressure, specific gravity, viscosity, and surface tension.

(2) Nozzle factors, comprising size and shape of the channels and apertures through which the fuel passes.

(3) Combustion-air factors, comprising its density (pressure temperature and its state of stagnation or agitation.

At the Engineering Experiment Station of the Pennsylvania State College a general research is being carried out on the dependence of spray properties on the various governing factors. One branch of this research deals with the distribution of fuel in space.

The equipment for the investigation of dispersion consists of the following groups: (1) spray-producing equipment, (2) air chamber, (3) cup and rack for catching the spray. The equipment is known probably to many from previous visits at Penn State. It has been described also in a number of publications. (6, 7, 8, 9) Therefore only a brief description will be given.

The layout of the spray-producing equipment and of the air chamber is shown in the schematic drawing Fig. 2. An electric motor drives a flywheel through a variable-speed gearing, the extension shaft of the flywheel actuating the spray-producing equipment which it is desired to investigate.

Two injection systems were investigated:

(1) Constant-pressure injection with mechanically operated valve.

(2) Pump injection with hydraulically operated valve (Robert Bosch type). In the constant-pressure injection system the oil can be put under pressure by means of a hand-operated or of a power-operated pump. The nozzle proper is shown schematically in Fig. 3, and the dismantled parts are shown in the photograph, Fig. 4. The nozzle contains a co-axial spindle, the lapped and polished flat tip of which serves for a valve. It is lifted off from or pressed on to its seat whenever the lever arm is actuated by the cam. The characteristics of this nozzle are shown in Fig. 5, and the orifices used in connection with it are shown in Fig. 6.

The pump-injection system was driven from the variable-speed shaft by means of a chain-and-sprocket drive, as shown in Fig. 7. The nozzle used is the so-called pintle type, having a cylindrical guide pin, as shown in Fig. 8.

In experiments on sprays it is necessary to separate one single injection, but without altering thereby the conditions prevailing when continuously repeated injections are made. There are two

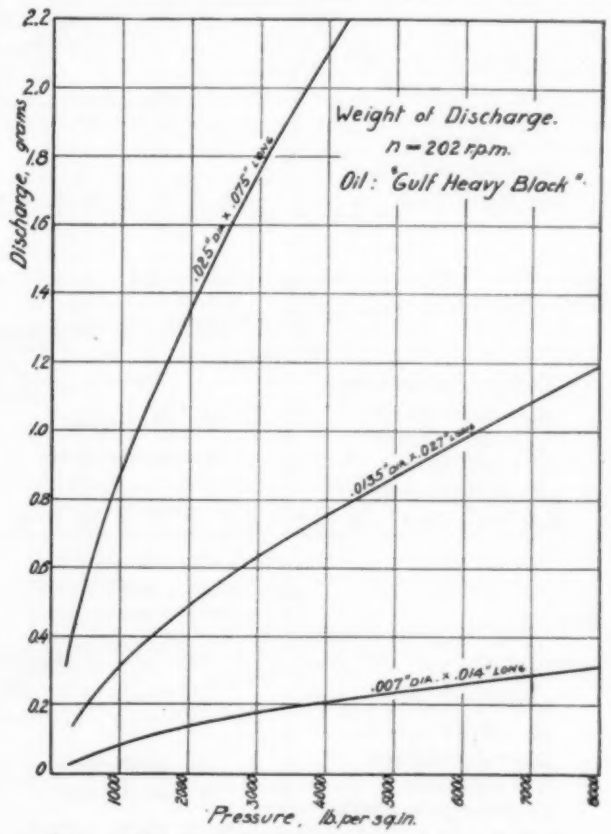

Fig. 14 Weight of Discharge With Various Orifices

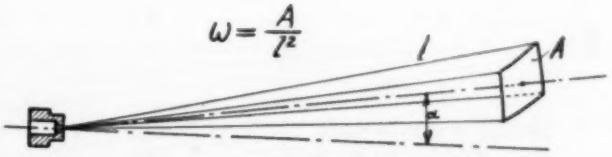

Fig. 15 Definition of Solid Angle

ways of accomplishing this: First, by actuating the flywheel, camshaft, and cam continuously at the specified speed, but preventing it from lifting the cam follower and the valve, except for a single injection. This method was used with the constant-pressure injection system. The second method is by actually producing repeated injections and shielding the measuring apparatus from all sprays except one. This method was used with the pump-injection system.

In both instances a so-called "selector mechanism" is used which moves the cam axially and thus brings it into engagement with its follower whenever a trigger is pulled. This mechanism is shown schematically in Fig. 9, which is largely self-explanatory. In the pump-injection system the shielding plate or "obstructor

plate" is actuated by this same cam mechanism, as shown in Fig. 10.

The nozzle is fixed, by means of a circular flange, to the air-chamber cover, which is a 2 in. thick steel plate of 20 in. diameter. It is bolted to a large cast-iron platform forming the foundation of the whole equipment.

The injection is made into the air chamber, which is a 36 in.

The apparatus used in dispersion experiments consists of two parts:

(1) The discharge cup for catching the total discharge of the spray.

(2) The dispersion rack for catching portions of the spray at definite locations in space.

The discharge cup is illustrated in Fig. 11. It is in reality a

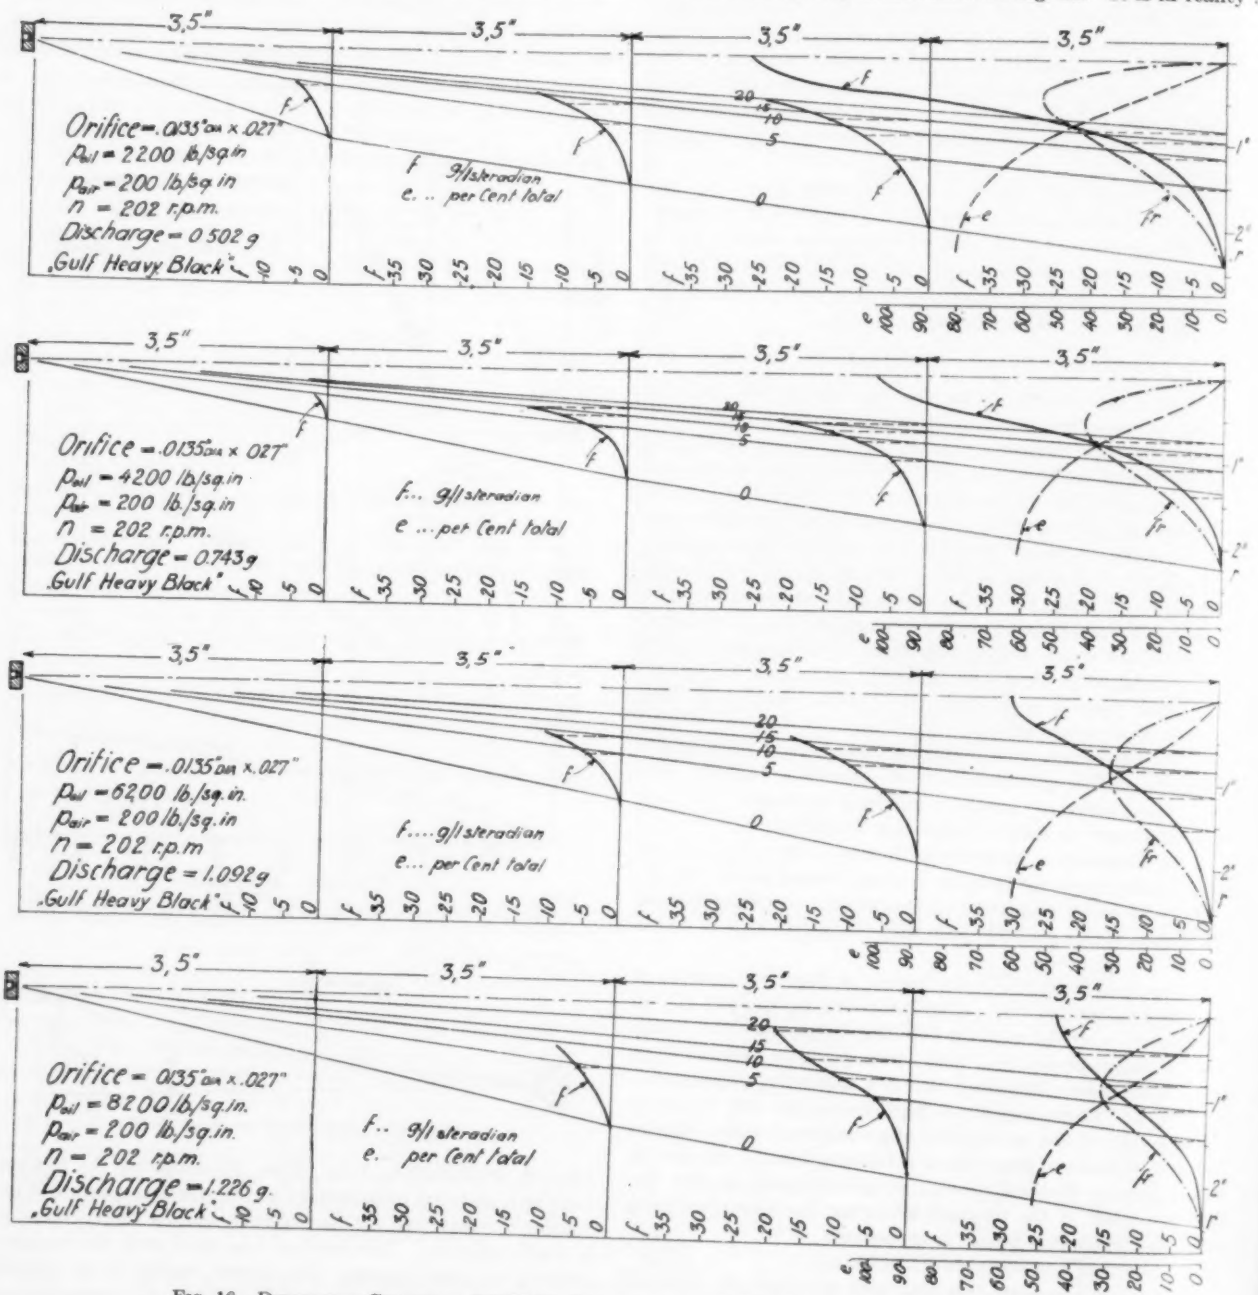

FIG. 16 DISPERSION CHARTS OF 0.0135 IN. DIAMETER BY 0.027 IN. ORIFICE IN COMPRESSED AIR

long piece of 10 in. diameter seamless-steel tube closed hemispherically on one end and arranged so as to be bolted hermetically to the chamber cover mentioned. The air chamber can be filled with air at any required pressure. The air is compressed by a motor-driven compressor and stored conveniently in a battery of steel bottles.

group of five cups, mounted on a sector. Each cup can be brought in front of the nozzle. The cups are filled with cotton waste or with some other absorbent material, and from their increment of weight after injection the weight of the injected fuel can be calculated.

The dispersion rack is a skeleton upon which absorbent pads

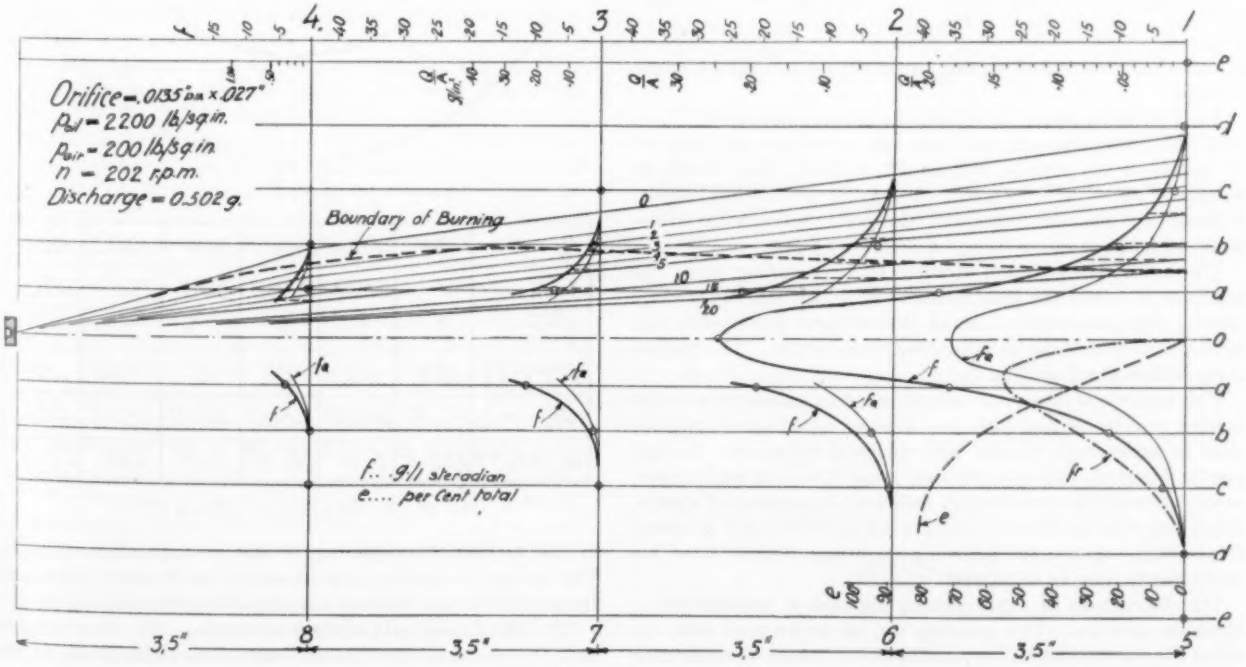
FIG. 17 DATA SHEET ON TEST

can be fastened for intercepting the spray at a number of predetermined locations in space (Fig. 12). The dimensions of the pads are given in Fig. 13. In the experiments here to be described 41 pads were used on the rack. In carrying out the experiments, first of all discharge tests were taken. A chart of the discharge weights with various oil pressures and orifices is shown in Fig. 14. Then the dispersion rack is put in place and carefully lined up co-axially with the spray. The chamber is closed and filled with air at the required pressure, and then one or two injections are made.



After this the chamber is opened up, and the weight increment of the pads is determined. In view of the large number of weighings a sensitive spring balance (Paulin, Roller-Smith type) was used which greatly reduced the weighing time and maintained satisfactory accuracy. Much attention was given to developing a method of representation for the spray pattern. The weight increment of the pad is equivalent to the quantity of oil passing, during the duration of the spray, through that area in space occupied by the pad.

Dividing the amount of oil by the area of the pad, the value "spray per unit area" $z = Q/A$ is obtained. It is preferable, however, to refer the spray weight instead of the area, which is a dimensioned quantity, to the enclosed solid angle, which is a non-dimensioned quantity. It is to be recalled that the solid angle is the ratio of a portion of a spherical surface to the square of the radius $\omega = A/l^2$, which concept is illustrated in Fig. 15. The unit of solid angle is "one steradian," this being $1/4\pi$ part of the complete sphere. Using this as reference, the "spray weight per unit solid angle" $f_\omega = Q(l^2/A)$ is obtained, which shall be called by the name flux, for the sake of brevity.

In an ideal spray which has no loss and no resistance, and with its particles traveling in a straight-line trajectory, the "spray weight per unit area" value decreases with the square of the distance, while the "spray weight per unit solid angle" is constant along a given trajectory.

All these values refer to a given total weight of spray, which latter is of no particular interest, since evidently a given quan-

FIG. 18 (BELOW) CHART OF A DISPERSION TEST

tity of oil can be dispersed by both a large orifice in a short time (or in a lesser number of injections) or by a small orifice in a longer time (or in a larger number of injections). In order to arrive at a representation of spray which would be a measure of the dispersing ability of a given orifice, oil pressure, and air pressure combination, it is of interest to refer the discharge to unit weight, i.e., to divide all the f_Q values by the total weight of discharge. This quantity is called "specific flux" $f = \frac{1}{Q_{total}} \frac{Ql^2}{A}$ and it can be defined as the dispersion of one gram of oil in a given direction.

The table shown in Fig. 17 gives the measured and computed data from a dispersion test with varying oil pressures, and Fig. 18 shows the chart corresponding to this spray.

In the experiments with round orifices it can be assumed that the dispersion is the same in all meridional planes. On this assumption the total amount of spray reaching a given cross-section can be determined from the dispersion chart. The amount is always less than the total discharge because, owing to air resistance, parts on the outer fringe of the spray lose their velocity

FIG. 19

at certain distances and do not advance to more distant cross-sections.

The flux being equal, $f_Q = l^2(Q/A)$, or more accurately, $f_Q = l^2(dQ/dA)$, and assuming that the flux values are the same at all points of the annular surface $dA = 2\pi r dr$, then it can be written $\int dQ = (2\pi/l^2) \int f_Q r dr$. Using the specific flux values, Q becomes e, i.e., the fraction of one gram reaching the cross-sectional surfaces in question: $e = (2\pi/l^2) \int f r dr$.

The actual computation consists in constructing, first, the auxiliary fr curve, the integral curve of which represents the e curve. The maximum value of this integral curve gives the total quantity reaching the respective cross-section. The method is applied on the chart Fig. 18.

This analysis of dispersion is applicable to, and may be a useful helping tool in dealing with, any kind of liquid spray, such as used in agriculture, textile, and chemical industries. In Appendix 3 is given a list of industries using sprays for various purposes, showing the considerable technical importance of sprays. Regarding now, specifically, a fuel spray to be burned in internal-combustion engines, the following quantities derived from the spray charts may be of interest:

(1) Percentage of spray passing through a precombustion-chamber aperture. This quantity can be determined, with the aid of the f or the e curve, by drawing the ordinates corresponding

to the boundary of aperture of the precombustion chamber. This method of application is shown on Fig. 19, which represents the precombustion chamber used in a Venn Severin engine.

(2) The theoretical boundary of burning. Let it be assumed that the chemical combination commences immediately at the

orifice and lasts until all the oil in the spray is consumed. Then the spray will be completely burned at such distance that the corresponding cone element contains the air necessary for combustion. The weight f of fuel requires a weight of air αf for its combustion (α = 12–15, depending on the composition of the fuel). The volume of this air is $V = (\alpha f/\rho)$; ρ being the weight of unit volume of air at the given density. Denoting by y the distance to which the spray can travel before its complete combustion, then the volume of the corresponding spherical sector having one steradian inclosed angle can be expressed by $V = \frac{1}{3} y^3$. From which $y = \sqrt[3]{(3\alpha f/\rho)}$.

Measuring up this distance on the corresponding radii vectors, a surface is obtained which is characteristic of the spray in so far as it represents the shape of that minimum container in which the spray can burn completely. The meridional curve of such a body is shown in Fig. 18.

A large number of charts representing sprays under various conditions will be published in a bulletin of the Pennsylvania State College which is now in preparation. (See Fig. 16.) These seem to point to the following general conclusions:

(1) The dispersion becomes more even when the injection pressure is increased
(2) The dispersion becomes more even when the oil viscosity is decreased
(3) The dispersion becomes more even when the air density is increased
(4) The cone angle increases with increasing oil pressure, increasing air density, and decreasing viscosity of oil
(5) A larger percentage of oil reaches a given distance in a spray having a slenderer spray cone
(6) No definite influence of orifice dimensions was noticeable in using cylindrical orifices of the dimensions employed in the tests discussed.

Finally, one conclusion has to be emphasized: that the experimental method described and the procedure of evaluation developed are easy to apply, and the results give a ready means of judging the spray from the point of view of its applicability in an engine. It is recommended as a useful tool in development work in oil-injection engines, and its general adoption is likely to lead to a better understanding of the influence of spray pattern on the performance of the engine.

These investigations were carried out under the general direction of R. L. Sackett, dean of the School of Engineering, and Prof. F. G. Hechler, head of the Engineering Experiment Station. In both the theoretical and experimental work Dr. P. H. Schweitzer, associate professor of engineering research, contributed several suggestions. O. F. Zahn, Jr., graduate assistant, made the greater part of the experiments and worked out the large number of numerical computations with painstaking care.

Appendix 1

ENERGY OF INJECTION

(1) *Solid Injection.* Pressure energy of oil:

$$L_o = G_o \frac{P_1 - P_2}{\gamma_o}$$

Example: Assumed values in metric units:

G_o = 1 gram = 0.001 kg.
γ_o = 900 kg. per cu. m.
P_2 = 35 at. = 350,000 kg. per sq. m.
P_1 = 250 at. = 2,500,000 kg. per sq. m.
$L_o = \frac{2150}{900}$ = 2.39 m-kg. per g. = 7840 ft-lb. per lb.

(2) *Air Injection.* Expansion energy of air assuming isothermic expansion:

$$L = G_a RT \log_e \frac{P_1}{P_2}$$

Example: Assumed values in metric units:

G_a = 1 gram = 0.001 kg.
R = 29.97
T = 323 deg. abs. = 50 deg. cent.
P_2 = 35 at. $\frac{P_1}{P_2} = 2$; $1 \log_e \frac{P_1}{P_2} = 0.6931$
P_1 = 70 at.
L_a = 6.56 m-kg. per g. = 21,500 ft-lb. per lb.

Using 2 gram of air for the injection of 1 gram of oil, the total energy is:

$$L_{total} = 2 L_a + L_o = 2 \times 6.56 + \frac{10{,}000\,(70 - 35)}{900 \times 1000}$$
$$= 13.32 + 0.39 = 13.71 \text{ m-kg. per g.} = 45{,}000 \text{ ft-lb. per lb.}$$

In order to supply the same amount of energy with solid injection, P_1 pressure has to be employed.

$$L_{total} = 13.71 = \frac{P_1 - 350{,}000}{900 \times 1000}$$

P_1 = 1270 kg. per sq. cm. = 18,100 lb. per sq. in.

Appendix 2

TOTAL SURFACE OF ATOMIZED DROPLETS

One gram of oil has a volume V_1 = 1/0.900 cu. cm. = 1.11

cu. cm., equivalent to a sphere $V_1 = \frac{4}{3} R_1^3 \pi$ having a radius $R_1 = \sqrt[3]{3V_1/4\pi} = 0.64$ cm.

The surface of this sphere is $A_1 = 4\pi R_1^2 = 5.15$ cm.

When this compact sphere is broken up into n droplets of r_n radius, the following relations hold:

$$V = \frac{4}{3} R_1^3 \pi = n \frac{4}{3} r_n^3 \pi; \quad r_n = R_1 \frac{1}{\sqrt[3]{n}}; \quad \frac{R_1}{r_n} = \sqrt[3]{n}$$

$$A_n = n 4\pi r_n^2 = \sqrt[3]{n} A_1 = \frac{R_1}{r_n} A$$

i.e., the area is increased $\frac{R_1}{r_n}$ times.

This area is equivalent to the surface of *one* sphere of R_n radius: $A_n = 4\pi R_n^2$; $R_n = \sqrt{\frac{A_n}{4\pi}} = \sqrt[6]{n} R_1 = R_1 \sqrt{\frac{R_1}{r_n}}$

The increased area is equivalent to spreading out the oil in a δ thickness

$$\delta = \frac{V_1}{A_n} = \frac{r_n}{3}$$

The energy due to surface tension is:

$$W_n = \sigma A_n$$

Assuming a surface tension $\sigma = 0.003$ kg. per m.,

$$r_n = 0.0002 \text{ cm.}; \quad A_n = \frac{R_1}{r_n} A_1 = 16{,}400 \text{ sq. cm.}$$

then

$$W_n = 0.005 \text{ kg-m.}$$

In a sphere the surface tension σ causes a pressure p for which the following equation holds:

$$\sigma 2r\pi = p r^2 \pi$$

$$p = \frac{2\sigma}{r}$$

In a droplet of $r_n = 0.0002$ cm. radius, the internal pressure due to surface tension becomes: $p = 0.3$ kg. per sq. cm. = 4.2 lb. per sq. in.

Appendix 3

APPLICATION OF SPRAYS

I Combustion
- 1 Engines, carburetor type
- 2 Engines, oil-injection type
- 3 Oil furnaces for industrial and household use

II Textile and Related Industries. Humidification of air in the manufacture of
- 1 Textiles
- 2 Rayon
- 3 Paper
- 4 Photo films and sensitized paper
- 5 Hides

III Agriculture and Food Industries
- 1 Artificial rain
- 2 Spraying insecticides (tree fruits, vines, potatoes, corn, etc.)
- 3 Spraying for destroying weeds
- 4 Manufacture of evaporated milk

IV Chemical Industries
- 1 Oxidation and reduction
- 2 Washing of gas
- 3 Dust and smoke precipitation
- 4 Acceleration of chemical reactions

V Deposition of a Thin Layer of Material
- 1 Painting, varnishing
- 2 Metals (Schoop's process)
- 3 Quartz (for large astronomical mirrors)
- 4 Concrete (Gunite process)

VI Medical and Sanitary Applications
- 1 Inhalators, throat sprayers
- 2 Disinfectors, perfume atomizers
- 3 Air conditioning
- 4 Dust precipitation

VII Miscellaneous
- 1 Fire extinguishers
- 2 Car washers

Discussion

K. J. E. Hesselman.[3] The researches carried out on oil-spray dispersion are extremely valuable and interesting. It was of great interest to see that researches have been made which the writer during practical work with oil motors has found desirable and necessary and which he also partly carried through in a similar way. There is no doubt that it is of the greatest importance for development that such researches have been made and published for engineers working in this field.

F. Sass.[4] The writer has followed the researches of the Pennsylvania State College with great interest from the very beginning and has derived valuable information, especially from the ingenious experiments on spray formation carried out by Mr. De Juhasz and Dr. Schweitzer. In the development of the solid-injection oil engine much credit is due to these investigators for their contribution to the knowledge of the characteristics of oil sprays. This knowledge is of great value to the engine designer, providing him with a surer basis for his design. In fact, more is known today about solid injection than about air injection, and this is greatly due to the investigations carried out at Pennsylvania State College.

None of the statements contained in the paper is in disagreement with the writers own experiments. Among the findings of the author it is particularly noteworthy that evacuating the space into which the spray is injected does not alter materially the characteristics of the spray. This is an important evidence against the theory which attributes the spray formation chiefly to air friction. In another place the author has already given expression to his doubt about this hypothesis.

One may look forward with particular interest to the publication on the dispersion of oil sprays, as stated by the author. In case further investigations should be carried out at the Pennsylvania State College on the penetration of sprays—which is also important for the design of solid-injection oil engines—then in the writer's opinion direct observation by means of spark photography would be highly desirable. To the writer's knowledge, at Pennsylvania State up till now only the indirect method of the ballistic pendulum has been used, similarly to the one used previously by Riehm. In this method it is unavoidable—even if only one single injection is made—to impart a momentum also to an unknown mass of air. Thereby to the impacting mass of oil the unknown mass of air is added, which introduces an error

[3] Stockholm, Sweden.

[4] Allgemeine Electricitaets-Gesellschaft, Berlin, Germany.

into the calculation of the spray velocity from the impact-force equation $P = mv$. For this reason the ballistic pendulum cannot supply as accurate data as can be obtained by means of the spark photography method.

R. A. CASTLEMAN, JR.[5] In considering the mechanism of the atomization that accompanies solid injection, it seems hardly necessary to point out again that "air stream atomization" only was specifically treated in the paper to which reference (1) applies and that solid injection was merely included as a case evidently physically similar as regards the relative motion of gas and liquid at their interface. The necessity for this method of treatment arose from the fact that Rayleigh's analysis could only be applied when the ligament size was known, and this had to be computed from that of the drops formed when a liquid is atomized; and the latter appeared to have been satisfactorily determined only for "air stream atomization." However, Sass has recently made preliminary reports (F. Sass, "Kompressorlose Dieselmaschinen," Springer, 1929, p. 45) on results of drop-size measurements in solid injection performed at the A.E.G., in which a method apparently initiated by Woltjen (Woltjen, Tech. Hochschule at Darmstadt Dissertation, 1925) was used. In this the spray is injected into a high-pressure chamber, where it is caught in a "dispersing liquid" and the drops are examined microphotographically. While these results show many perhaps surprisingly large drops and considerable distribution of drop sizes, they also show many drops small enough to account for a similar mechanism in this case. It will appear later that both the larger drops and the size distribution are to be expected.

Now there are evidently other forces acting simultaneously in this case (say those due to fluid friction in the nozzle), so it seems important to consider whether, and in how far, experiments really indicate that this simple theory cannot be applied to solid injection.

Considering first the results of the Pennsylvania State tests which are claimed to disprove the influence of surface forces:

(*a*) The observed effect on drop size is not very clear, but it is gathered that this did not appear to change much with air density, nor is the method of measuring this drop size apparent. The familiar N.A.C.A. pictures indicate the absolute impossibility of estimating the drop size in such a spray, even when aided by the electric spark. Sass (loc. cit., p. 46), however, reports considerable and consistent increase in drop size with decrease in air density, thus indicating dependence of drop formation on surface forces.

(*b*) The reported observations of the effect of air density on cone angle are to be expected. Joachim and Beardsley found (N.A.C.A. Report No. 268, 1927) (1) a decrease of cone angle, for a "non-centrifugal" spray, from about 22 deg. at 200 lb. per sq. in. chamber pressure to about 8 deg. at atmospheric; (2) a simultaneous increase in cone angle for a spray deliberately made "centrifugal." Recognizing that any liquid injected at such high speeds must have some radial velocity on account of turbulence, it seems that (2) may equal (1), and one would not expect much further change in cone angle when the air density is reduced to a very low value; in other words, the effect reported in this paper seems to be due to the mechanical action of the medium on the drops after their formation.

Considering next the probable bearing of some other observations:

(1) It has been recognized for some time that there is marked drop-size inhomogeneity in sprays formed by solid injection, and the importance of this as regards penetration was noted. The degree of this inhomogeneity was only recently revealed, however, by some experiments at Langley Field, when Rothrock (N.A.C.A. Tech. Note No. 376, May, 1931), tearing away the enshrouding veil of small drops with a high-speed air stream, revealed a very coarsely "atomized" core. Now this is to be expected if the "atomization" is due to surface forces: The velocity difference between air and liquid would be greatest at the outer cone element; as the interior is entered this relative speed drops to a value probably too low for atomization. This, however, seems to account for both the very large drops (which cannot be completely gotten rid of even by the use of very high injection pressures) and the size distribution reported, for instance, by Sass (loc. cit.).

(2) The familiar appearance of these jets, that the atomization seems to occur very close to or even within the nozzle, is also to be expected. The velocity difference is greatest at this point (both the air is accelerated and the liquid decelerated in further progress); so that the interfacial forces must act then if at all. Ligaments fine enough to break up into the smaller drops observed in the spray would have life periods of the order of only 10^{-5} sec.; so that they would collapse within 1 or 2 mm. of the nozzle, which is consistent with N.A.C.A. observations.

It thus appears that close examination of the experimental results so far reported shows that none really seems to prove that surface forces do not influence atomization in solid injection, while much can be found to support this view. Remembering (1) how easy it is to ruffle the surface of a liquid, (2) the very brief life period of ligaments fine enough to break up into the smaller drops found in the spray (order of 10^{-5} sec.), and (3) the manner in which the surface forces are constrained to act, it seems legitimate, at least until real evidence to the contrary is produced, to adopt the pleasing simplicity of the explanation that seems to suffice for air-stream atomization, and thus get just as clear a mental picture in the case of solid injection.

Credit is due the author for recognizing the need for further argument in the case of solid injection.

P. H. SCHWEITZER.[6] Attention has been called to the advantage of the square-edged orifices in producing a better dispersion than those obtained by rounded orifices.

It has to be admitted that as a rule the square-edged orifices do produce better atomization and dispersion than those used in our experiments. In spite of that, the use of square-edged orifices is discouraged in engines, for two reasons. First, it is very hard to produce a geometrically correct, clean square-edged orifice; and still more so, several of them with an equal hydraulic resistance and discharge. Second, square-edged orifices that are so in the beginning do not stay that way. The scouring action of the oil passing through rounds off the edge of the orifices. The discharge coefficient of a short square-edged orifice is about 0.65 and that of a slightly chamfered orifice is 0.80. If one places a square-edged orifice in the oil line, the discharge coefficient rises in a few days from 0.65 to 0.80. Microscopic examination reveals a slight rounding of the edges by use.

We started out using square-edged orifices for scientific experiments for reproducible results. We abandoned that in favor of chamfered orifices, which we obtain by rubbing emery powder against the edges of the orifice, the chamfer amounting to 0.004 to 0.005 in. We found that small differences in the amount and angle of the chamfer do not make as much difference as unavoidable burrs and irreguiarities in square-edged orifices.

A. M. ROTHROCK.[7] The work that is being conducted at the Pennsylvania State College on the dispersion and energy of the fuel spray in conjunction with the work that is being conducted

[5] Assistant Physicist, Bureau of Standards, Washington, D. C.

[6] Associate Professor of Engineering Research, Pennsylvania State College, State College, Pa.

[7] Associate Physicist, Langley Field, Va.

at the Langley Memorial Aeronautical Laboratory on the spray penetration, formation, and atomization are giving us a better concept of the laws which control the actions of the fuel spray in the compression-ignition engine. The writer is particularly interested in Professor De Juhasz's statements regarding fuel sprayed into a vacuum. The laboratory has also done some work along this line. With the N.A.C.A. spray photography equipment we have taken high-speed motion pictures of sprays injected into an air pressure of 0.1 in. of mercury. The results were quite interesting. Of course the rate of spray-tip penetration was extremely high. The spray itself had a cone angle of approximately 2 deg. The photographs showed that there was no fuel torn away from the edge of the spray, as is the case when the fuel is sprayed into air at a pressure of 1 atmosphere. We have also photographed fuel sprayed into water. The photographs appeared similar to those of fuel sprayed into dense air, although the penetration was decreased. In regard to the dispersion of the spray into air at densities corresponding to those in the combustion chambers of compression-ignition engines, we made a very simple test of spraying against a piece of modeling clay mounted 5 in. from the nozzle. The spray made a small hole approximately $^1/_8$ in. in diameter in the clay, indicating that the greater part of the spray was contained in a cone with an angle of approximately 2 deg. This is in accordance with the results presented by the author. The writer agrees that the resistance to air is not the sole cause of the atomization of the spray. If the flow through the nozzle is turbulent, the jet is in an unstable condition as it issues from the discharge orifice.

Recent tests that were conducted at this laboratory, however, on atomization by Mr. D. W. Lee have shown that the atomization is not changed to any great extent by any of the means available for atomizing the fuel in a hydraulic injection system. We have measured the atomization of sprays from single round-hole orifices, of sprays from injection valves employing helical grooves, of sprays impinging against each other close to the nozzle, and of sprays injected against a metal plate close to the nozzle. Certainly if the atomization does not take place within the nozzle, it does take place within a fraction of an inch after leaving the nozzle. As a result of these tests the writer has come to the conclusion that higher mean effective pressures in the compression-ignition engine will be obtained only when there has been improvement in the uniformity of the dispersion of the spray, either by the methods listed or by the intelligent use of air flow. Dispersion tests made under these conditions would be extremely interesting. Of course, there is the possibility that the period of after-burning in the combustion chamber is partially caused by the ignition lag of the larger drops in the spray. In this case it will be extremely difficult to eliminate it.

The data that the author has presented are for injection periods of approximately 0.05 sec. His results show that under this condition, at an injection pressure of 2200 lb. per sq. in., 80 per cent of the fuel penetrated to a distance of 14 in. When the injection pressure was raised to 8200 lb. per sq. in., the quantity penetrating to 14 in. decreased to 26 per cent of the total fuel quantity. The writer would like to ask whether this is attributed to the decrease in the mean drop diameter caused by the increase in the injection pressure. (Incidentally should not the f curves be labeled "per cent of total per steradian" instead of "grams per steradian?") He would be interested in seeing the dispersion tests continued for injection periods of approximately 0.003 sec., since this time interval is approximately that used for the injection of the fuel in compression-ignition engines running at speeds of 1500 r.p.m. and over. Has the region from the nozzle to a distance of 3.5 in. from the nozzle been explored? The writer realizes the difficulties to be encountered in this region, but it is very necessary for those who are working with high-speed engines to know what the dispersion is in combustion chambers having a maximum length of not more than 4 in.

A. L. Bird.[8] The subject of spray formation is a fascinating one and has tempted many to try to go further than Lord Rayleigh, who proved the tendency to ripple formation at a boundary for low speeds, and to determine analytically the factors which decide that drops of a certain size shall be formed rather than others very much larger or smaller.

Probably the author is wise in concentrating on the investigation of the laws of behavior rather than those of formation, but his reference to injection into a partial vacuum is of particular interest in view of some similar experiments at Cambridge, England. Using a chamber 20 ft. long and 1 ft. diameter, exhausted to $^1/_{10}$ atm., some dispersion was still found, though not as much apparently as by the author; in fact, the splash scarcely covered the end cover of the chamber; whereas in the open the same jet did not reach 20 ft., the center of gravity of the deposited drops being about 10 ft. distant from the nozzle and the lateral spread some 2 ft. there. This result is preliminary only, and no special trouble was taken to select a good nozzle. Possibly with a smooth entrance and large length-to-diameter ratio, the dispersion might have been even less. It would appear to be necessary to distinguish also between nozzles with a small-lift value above them (in which the drops appear to emerge ready formed) and true orifices unaffected by any valve, the latter being the type mainly tried at Cambridge.

The results from the ingenious dispersion apparatus should be of great interest and usefulness. Conceivably in the future the author may be able to elaborate it so as to measure the impact on each of the platforms.

Author's Closure

It is gratifying and encouraging to note that the investigations into the basic phenomena of the fuel spray carried out at the Pennsylvania State College find interest among the ranks of the research fraternity as well as meet the endorsement of distinguished exponents of the practical development of the solid-injection oil engine. Thanks are due to all the discussors for their suggestions and constructive criticism.

Dr. Sass rightly recognizes the error inherent in the pendulum method of determining the mean velocity of the spray. It is to be borne in mind, however, that all velocity determinations have their errors and limitations. For example, the spark-photography method as used in the N.A.C.A. investigations and by the A.E.G. under the direction of Dr. Sass give only the velocity of the spray tip, which itself is changing, and is replaced by new oil every moment. The double-disk (stroboscopic and target disks) method (Ref. 8) gives the instantaneous values as an average over the distance of the disks. Therefore the various methods need the support of each other, and the most probable velocity values can be determined by checking and correlating the results obtained by each.

Regarding Mr. Castleman's discussion, the author wishes to emphasize the statement in his paper that the atomization and dispersion phenomena cannot be accounted for solely by the air friction forces. These forces, however, do have an important influence on the spray characteristics.

It is of interest to note that both Mr. Rothrock with the N.A.C.A. and Professor Bird in Cambridge carried out injection tests in rarefied air. Many of us would like to see published the spark photograph of such a spray, especially in conjunction with sprays injected into air at various densities, but otherwise under identical conditions, as spark photography is able to record finer details than are obtainable by any other means.

[8] Cambridge, England.

In experiments conducted at the Pennsylvania State College by Lieut. J. P. Thew, U.S.N., it was found that the fineness of atomization largely depended on the oil pressure, the drop size decreasing with the increase in pressure. The resulting increase in air resistance accounts for the decrease in the percentage of spray reaching a given cross-section, when the oil pressure is increased.

The *f* curves on the charts refer to the flux due to 1 gram of total discharge. Therefore the expressions "per cent of total per steradian" or "grams per steradian" are equally justified.

The exploration of smaller sprays would only involve making a dispersion rack of smaller dimensions all over, and a refinement in the weighing technique on account of the smaller weights to be measured. At Pennsylvania State the diameter of the spray cone at different distances from the nozzle was measured by means of a caliper fixed on the traveling platform of the spray pendulum. This method proved satisfactory and accurate.

It would be difficult to combine satisfactorily the function of a dispersion rack and the spray pendulum in one instrument. It is planned, however, to measure with the spray pendulum the momentum of any portion of a spray by simply placing in front of the pendulum plate a stationary plate which permits the passing of the spray portion to be investigated and shields the rest.

Owing to the small momentum of the outer portions of the spray, it is necessary to build the pendulum extremely sensitive. Such a modification has been tried out on our spray pendulum and may be further developed.

Experiments on the Flow of Air Through Engine Valves

By E. S. DENNISON,[1] T. C. KUCHLER,[2] AND D. W. SMITH,[3] PHILADELPHIA, PA.

The resistance of air flow through poppet valves has been tested experimentally by the authors. The experiments which they carried out and describe include flow in both inlet and exhaust directions, and the ranges of valve opening and of pressure head extend to or beyond the limits which normally may be utilized in practice. Individual valves were tested variously mounted, and pairs of valves were tested as grouped in an actual design.

The experiments have been extended in an effort to improve the flow characteristics of the poppet valve by modification of its shape and that of the valve approaches.

E. S. DENNISON

T. C. KUCHLER

D. W. SMITH

THE choice of valves and gear for a high-speed internal-combustion engine is limited by space, by permissible mass and acceleration of the parts, and by the necessity for reducing throttling losses. Features which must be determined include the choice of number, size, and type of valve, the disposition of valves and passages, and the determination of valve-operating-gear details.

So far as the problem is purely mechanical in nature, as it is when dealing with the valve-operating gear, it may be rationally dealt with upon the basis of known properties of materials, and of familiar physical laws. But a rational treatment of the whole problem requires a similar accurate knowledge, either analytical or empirical, of laws governing the flow of air through valves and adjacent passages.

There is perhaps no existing knowledge which would permit an analytical treatment of the flow characteristics of an ordinary poppet valve as mounted in a practicable engine design. Data suitable for design purposes must be found experimentally, and several investigators have given their attention to securing such information.

An examination of the existing data brought out several conditions which seemed to justify further work in the field. In the first place, the information was found to be incomplete and to apply to only a few forms of valve assembly. Furthermore, it showed that considerable differences of behavior might result from even a minor change in the valve or port design. Secondly, no published data exist on the effect of a curved approach passage as usually designed, nor of grouping valves in a pair in conjunction with a single passage; certainty in this respect could be had only by a test of the valves in place in the actual cylinder head. Thirdly, it seemed that there was a possibility of improving upon the usual type of poppet valve as an element in a fluid conduit system. A part of the program was therefore directed to the latter object, without a view to any immediate application in practice.

Questions which appeared to have been adequately answered by the work of previous investigators were not reopened. A review of a few published results is given here, in order that the reasons for limiting the direction of the present work may be apparent. A mere check on results already at hand was not sought after.

Summary of Published Experimental Results

Nutting and Lewis.[4] A limited series of experiments was made on the flow of air in the intake direction through various valve combinations into a model combustion chamber of 5.75 in. diameter joined to a cylinder of 5 in. diameter. The combinations included a single $2^1/_2$-in. valve, two $1^3/_4$-in. valves in parallel, and two $1^1/_4$-in. valves in parallel. Each valve of a pair was

[1] Section Engineer, Four-Cycle Oil-Engine Section, Westinghouse Elec. & Mfg. Co., South Philadelphia Works. Jun. A.S.M.E. Mr. Dennison is a graduate of the Massachusetts Institute of Technology, class of 1921, with the degree of S.B. in Mechanical Engineering. His first position was with the Carbondale Machine Company, Carbondale, Pa. In 1922 and 1923 he was employed by the U. S. Board of Helium Engineers, Washington, D. C., in the calculation of gas-liquefaction processes used in the extraction of helium gas, and in low-temperature research. From 1923 to 1927 he was employed by the Curtis Oil Engine Company, New York City, in the development of a supercharged high-speed Diesel engine. After a brief connection with the Doherty Research Corporation, New York, he joined the Westinghouse Company as development engineer. He has subsequently taken charge of design and other engineering activities relating to high-speed oil engines of the four-cycle type.

[2] Oil-Engine Division, Westinghouse Elec. & Mfg. Co., South Philadelphia Works. Jun. A.S.M.E. Mr. Kuchler was graduated in 1926 from the Swiss Federal College of Science, as a pupil of Dr. A. Stodola. From 1926 to 1928 he was employed by Sulzer Bros., Winterthur, Switzerland, as a draftsman in the marine Diesel engine department. He has been connected with the Westinghouse Company since 1928, and has been engaged in research and development in connection with high-speed oil engines.

[3] Oil-Engine Division, Westinghouse Elec. & Mfg. Co., South Philadelphia Works. Jun. A.S.M.E. Mr. Smith was graduated from Pennsylvania State College in 1929, with the degree of B.S. in M.E. Previous to this, he was employed as a draftsman for four years by the Union Switch and Signal Company and the Westinghouse Company. During this time he took engineering work in the night school of Carnegie Institute of Technology. After receiving his degree from Pennsylvania State College, he returned to the Westinghouse Company at East Pittsburgh, where he was engaged for a year and a half as a member of the student engineering course, the mechanical design school, and in the mechanical engineer's office. He was then transferred to his present location.

Presented at the National Oil and Gas Power Meeting, University of Wisconsin, Madison, Wis., June 23–26, 1931, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

connected to an individual curved air passage. Details of valves, passages, etc., are not given. It is not stated that all valves were geometrically similar, although this seems to be assumed in their interpretation of the results. The tests covered a full range of valve lifts, and pressure heads up to 28 in. of water at small openings.

Their results showed a decreasing coefficient of discharge with increasing lift. The coefficient of discharge, when plotted on a non-dimensional basis against Lift/Port Diameter showed substantial identity for the $1^3/_4$-in. and $2^1/_2$-in. valves. Results for the $1^1/_4$-in. valves were at variance; the latter results were discounted by the original authors because of a special condition in the air passage.

Experiments of this character usually involve the assumption that results obtained with one size of valve may be applied to similar valves of other sizes, provided that geometrical proportions of the adjacent parts are also similar. This should be

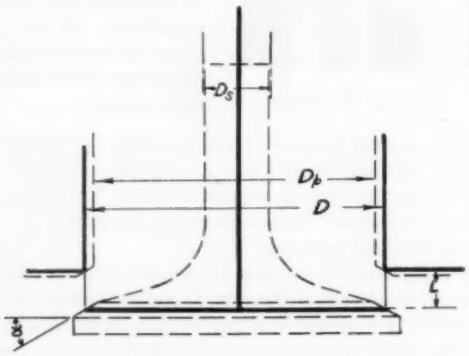

FIG. 1 ELEMENTARY DISK VALVE

correct except for the part played by surface friction, which presumably is small. The same assumption is used in the interpretation of most wind-tunnel results. The experiments of Nutting and Lewis partially confirm the assumption as it applies to valve flow, and the experiments described in the present paper have been limited to one size of valve.

Their report remarks (p. 19): "Venturi effects in the passage immediately above the valve might be productive of excellent results." Seemingly no attempt was made to follow this suggestion further.

Tanaka.[5] The extensive work by this author is notable for thoroughness and for refinement of method. A very lengthy series of tests was made with air flow through both inlet and exhaust valves. These cover the full range of valve lifts with various pressure drops. The effect of variation in valve details was systematically studied. Features which were progressively varied included the angle of cone seat; projected width of seat, or overlap; valve-fillet radius, and valve-head angle. Model valves were tested in a concentric apparatus in connection with a simple cylindrical port with the approach rounded at the inlet side. The result of these experiments is largely to confirm accepted valve practice, since only minor differences are found by variations of the above-mentioned features within practicable limits. For example, cone seat angles of 30 deg. and 45 deg. are roughly equivalent in result, whereas with a 60-deg. angle the resistance becomes excessive.

Sharp discontinuities of flow were found, occurring at definite valve lifts, and in some degree modified by changes in pressure head. Four distinct modes of flow are noted, and a discontinuity corresponds to a shift from one mode to another. The differences of flow are found to be associated with sharp corners at the edges of the valve and valve seat. The existence of four types of flow was proved by photographs and confirmed analytically. By rounding all corners to a radius of 4 mm. (0.158 in.), the sharp discontinuities are nearly obliterated, and resistance of the valve is decreased. Tanaka finds the rounding of these edges to be the most advantageous means of improving valve flow. He remarks that rounding of the corners in effect makes a convergent-divergent nozzle of the crevice between valve and seat, but it is surprising to note that he does not attempt to extend the application of the principle.

Schrenk.[6] Experiments were made upon the resistance to flow of water in the inlet direction through plate valves with square and conical seats. With flat plate valves, two principal types of flow were found. Valves having cone seats showed at least six types with possible minor variations.

A type of valve was developed employing a rounded nozzle inlet and a diffuser-type discharge. Resistance by this means was reduced to a small fraction as compared with the worst case (flat-seated valve with all edges sharp).

The valves tested were not of the poppet type, and the improved valve, unfortunately, is not applicable to engine purposes.

The subject was treated analytically by Eck.[7] He applies his work to the experiments of Schrenk and finds that mathematical explanations are possible of the types of flow which were observed. As yet no attempt has been made to apply his methods to the results here presented.

FACTORS CONTROLLING AIR FLOW THROUGH VALVES

NOMENCLATURE

D = mean diameter of valve seat, in.
D_s = valve-stem diameter, in.
D_p = valve-port diameter, in.
L = valve lift, in.
A_l = valve "limit area," sq. in.
= πDL when $L < D/4$
= $\pi D^2/4$ when $L > D/4$
A_a = actual minimum flow section at valve, sq. in.
A_n = "unity orifice" area, namely, the area of an imaginary orifice with unity coefficient of flow, which is the calculated equivalent of an actual valve under given conditions, sq. in.
μ = A_n/A_a = orifice coefficient of the valve, based upon actual minimum section
ψ = A_n/A_l = ratio of equivalent orifice to "limit area"
γ = ratio of absolute pressures before and after valve.

ASPECTS OF VALVE OPENING

"Limit Area" A_l. The port diameter D_p is frequently used as a measure of valve size. For purposes of the present discussion the mean seat diameter D is preferred, and is generally used throughout. This preference is due firstly to the fact that the mean diameter corresponds more closely to the elementary disk valve which might replace the actual valve and which determines the mass of the valve and its gear. (See Fig. 1.) Secondly, the

[7] Bruno Eck, "Potential Flow in Engine Valves," Translation Tech. Memo. no. 343, N.A.C.A., Washington, 1925.

use of D_p carries with it the assumption that the port is to be of simple cylindrical form down to the seat of the valve. This was not the case in all tests, and was found to be in some respects undesirable. These considerations lead to the definition, limit area $= \pi DL$, with a maximum of $\pi D^2/4$, as a measure of the capacity provided in the valve gear.

Actual Area A_a. The actual area is determined from the detail dimensions of the valve and its seat, according to the following equation:

$$A_a = 2\left(R_0 + \frac{L}{2}\sin\alpha\cos\alpha\right)L\cos\alpha \quad \ldots\ldots [1]$$

in which R_0 = inner radius of valve seat $= D_p/2$, and α = valve-seat angle. With large lifts a maximum opening equal to

$$A_a \text{ max.} = \frac{\pi}{4}(D_p^2 - D_s^2)$$

is attained. Where a test is made with the valve removed, A_a becomes $\pi D_p^2/4$. The calculation of area for the special form of valve had to be done graphically for some openings.

Table 1 summarizes the numerical values applying to valves used in the various tests.

TABLE 1 NUMERICAL CONSTANTS FOR TEST VALVES

[1] Diameter of throat above valve.

"Unity Orifice" Area. The third aspect of valve opening, namely, the area of the equivalent "unity orifice" is defined as $A_u = \mu A_a$. The overall efficiency of the valve set is given by

$$\Psi = \frac{A_u}{A_l} \quad \ldots\ldots [2]$$

particularly for design purposes. The importance of actual area A_a and of the true coefficient μ lies in their combined effect in the product μA_a.

Valve as Orifice or Nozzle

The familiar treatment of a valve is as a more or less restricted orifice opening into the cylinder. In this case the flow may be calculated by any of the usual formulas for air flow under a moderate head, such as that of Moss for "Normal Air,"[8]

$$G = 157.6 A\mu\sqrt{\left(P_1 - P_2\right)\frac{P_2}{T_1}} \quad \ldots\ldots [3]$$

where G = air flow, lb. per sec.
A = nozzle area, sq. ft.
P_1 = total pressure (static plus velocity pressure) before nozzle, lb. per sq. in. abs.
P_2 = static pressure after nozzle, lb. per sq. in. abs.
T_1 = temperature before nozzle, deg. fahr. abs.
μ = coefficient of discharge.

[8] S. A. Moss, "Measurement of Flow of Air and Gas With Nozzles," Trans. A.S.M.E., vol. 50 (1928), no. 2.

Taking this view of the functioning of the valve, various steps are immediately suggested which may be expected to improve its performance. These are implied in the form of the equation, and in the known means of raising the discharge coefficient of a mouthpiece toward its limiting value of unity. They may be summarized as follows:

1 Employ large passages for approach and discharge. By this means friction will be minimized and the full pressure drop $(P_1 - P_2)$ will be available across the valve itself
2 Design the valve to give a large actual opening for a given lift. That is, a small seat angle is to be preferred to a large one
3 Round the edges of the valve and its seat, particularly on the approach side.

That this approach to the problem is capable of producing valuable results is shown particularly by the experiments of

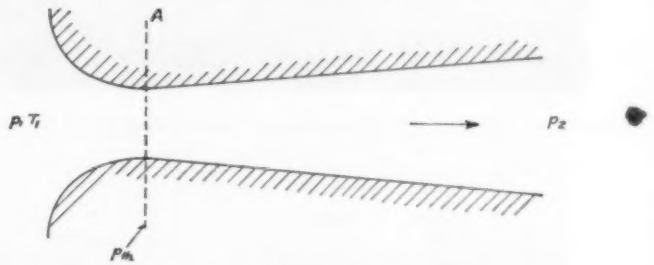

Fig. 2 Elementary Diffuser

Tanaka, already mentioned. The ideal limit is set approximately by the value $\mu = 0.98$ for a rounded mouthpiece; the practical limit is much lower, being imposed by construction requirements and by the unavoidable abrupt change in direction of flow in a poppet-type valve.

Valve as Diffuser

The limit $\mu = 1$ which applies to a rounded mouthpiece is removed if the valve and its passages be constructed to act as a diffuser. The phenomenon of a high throat velocity, with nevertheless, slight overall resistance or pressure drop, is common in the operation of venturi tubes. It seems that this form of construction has not had the application in the design of engine valves which its advantages merit. These advantages appear to be considerable, even after they are discounted—as they must be—on account of the practical design limitations which exist.

Theoretically, the flow of air or gas which will pass through an ideally constructed diffuser is limited only by approach to the velocity of sound at the throat. This in turn is established by the existence in the throat of the critical pressure, namely:

$$P_{th} = \left[\left(\frac{2}{K+1}\right)^{\frac{K}{K-1}}\right]P_1 = 0.53P_1 \text{ (for air)} \quad \ldots\ldots [4]$$

in which P_{th} = static pressure in throat, lb. per sq. in. abs. Thus the flow through the diffuser is the same as the flow through a rounded orifice when $P_2/P_1 \leqq 0.53$, namely, in the form given by Moss[8]

$$G = \frac{76.367 A \mu P_1}{\sqrt{T_1}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

in which, in this instance, A is the throat area in square feet.

The ideal diffuser (see Fig. 2) will be capable of attaining this flow even when the overall pressure drop ($P_1 - P_2$) approaches zero as a limit.

The actual diffuser falls far short of this capacity even when conditions are favorable. Its losses are of two kinds: (1) Friction loss, both internal friction, due to turbulence of flow, and friction at the wall surface. (2) Inefficiency in the conversion of velocity head (at the throat) into static pressure head (at the point of discharge). Of the two, the loss by friction is comparatively small.

Referring to the sketch (Fig. 2), the diffuser is divided by the throat section (indicated by the broken line) into two parts. The upstream portion is no more than a rounded mouthpiece.

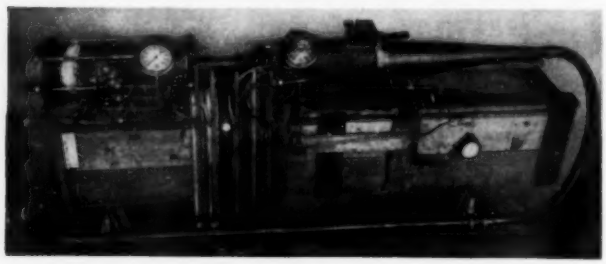

FIG. 3 PHOTOGRAPH OF TEST APPARATUS

true either in the ideal or actual cases. The actual diffuser case is irreversible and is accompanied by an increase of entropy. The increase of entropy may be traced to the two distinct sources of loss, that is, friction and inefficiency of diffuser action.

Difficulty in obtaining a good diffuser form in valve arrangement, particularly for the intake direction of flow, greatly narrows the possibilities of the principle. Its application may nevertheless be looked on as a possible means of going beyond the unity discharge coefficient.

DESCRIPTION OF APPARATUS

The test apparatus consists essentially of a flow meter followed by a suitable holding device for the model under test. Air entering the equipment flows first through the meter, then to the test valve, whence it is discharged to the atmosphere.

The general arrangement is shown by Figs. 3 and 4. The course of the air through the apparatus may be followed by reference to Fig. 4. The items referred to are readily discernible in the photograph, Fig. 3.

Air for the tests was drawn from the shop compressed-air line through a throttling valve. A tank about 30 in. in diameter and 8 ft. in height was secured and filled to a point near the top with coke. Air from the throttle valve entered near the bottom of this tank and flowed upward through the coke. Water was drained out at the bottom. Air after passing through this drier was free of water drops. Provision for heating by means of a steam coil was found unnecessary, and all tests were run at atmospheric temperature.

Entering the test apparatus, the air flows through a diffuser of 10 deg. included angle. This serves the double purpose of

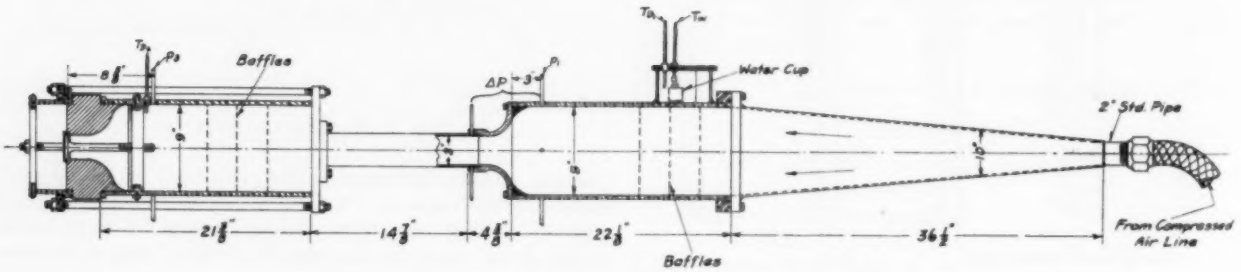

FIG. 4 GENERAL ARRANGEMENT OF TEST APPARATUS

Here the static pressure of air before the valve is converted into velocity head at the throat. In other terms, the internal energy of the gas is converted by adiabatic expansion into kinetic energy. The process is easily accomplished with little loss, the efficiency being perhaps 98 per cent. Downstream from the throat, the reverse process of restoring static head and internal energy proceeds in the expanding nozzle. This is less efficient. Under favorable conditions the efficiency may be 80 or 85 per cent. When the diffuser shape is not favorable it will be much lower. In any case where the included angle of the cone exceeds 8 to 10 deg., the diffuser action will be poor.

It may be noted that thermodynamically the ideal processes of flow, in the nozzle and in the diffuser, are fundamentally different. In the simple nozzle a finite flow requires a finite difference of pressure. The process is adiabatic and irreversible, and is accompanied by an increase of entropy. In the ideal diffuser, a finite flow may take place with only an infinitesimal difference of pressure. The case is then adiabatic and fully reversible. Internal energy is converted to kinetic energy, and is then fully reconverted to internal energy, and the process is isentropic. Both processes, when comparing initial and final states, are isothermal for air in continuous flow. The latter is enabling somewhat higher test pressures and of helping to quiet the flow of air before it enters the flow meter. Velocity distribution over the diffuser discharge area was checked and found uniform.

The diffuser discharges into a 9-in. cylinder fitted with three baffles through which the air flows toward the meter. Above this cylinder is mounted a box, opening into the cylinder and carrying dry-bulb and wet-bulb thermometers (T_{D1} and T_W). This equipment at first included also a small motor-driven fan. The latter was found unnecessary, since the disturbance of air movement in the cylinder was sufficient and the fan operation had no noticeable additional effect on the thermometer readings.

At the end of the 9-in. cylinder, the air passes to a 3-in. tube through a smoothly rounded mouthpiece. This tube is seamless drawn steel, accurate and uniform in diameter and smooth.

A pressure reading (p_1) is taken in the 9-in. cylinder, and a manometer to read pressure drop (ΔP) is connected from the cylinder to a point on the 3-in. tube. Both pressures are static pressures, the connecting tubes leading to small holes smoothly finished at right angles to the inner walls. At each point of measurement, three such holes are used, spaced around the circumference in one plane, and leading into a common pressure tube.

The 3-in. steel tube discharges into another 9-in. cylinder which also is fitted with baffles made of plate with progressively smaller perforations. After the baffles, the air passes to the model or cylinder head, through which it is discharged to the atmosphere. Readings of pressure (p_3) and temperature (T_{D2}) are made immediately before the test model.

sembly. A dial indicator is used in that case for setting the lift.

Pressures p_1 and p_2 are read with alcohol manometers up to about 27 in., then with mercury manometers to about the same height. Above this point, pressures are read with gages, these being checked at frequent intervals in the course of the work. The pressure drop ΔP is read with an inclined alcohol manometer

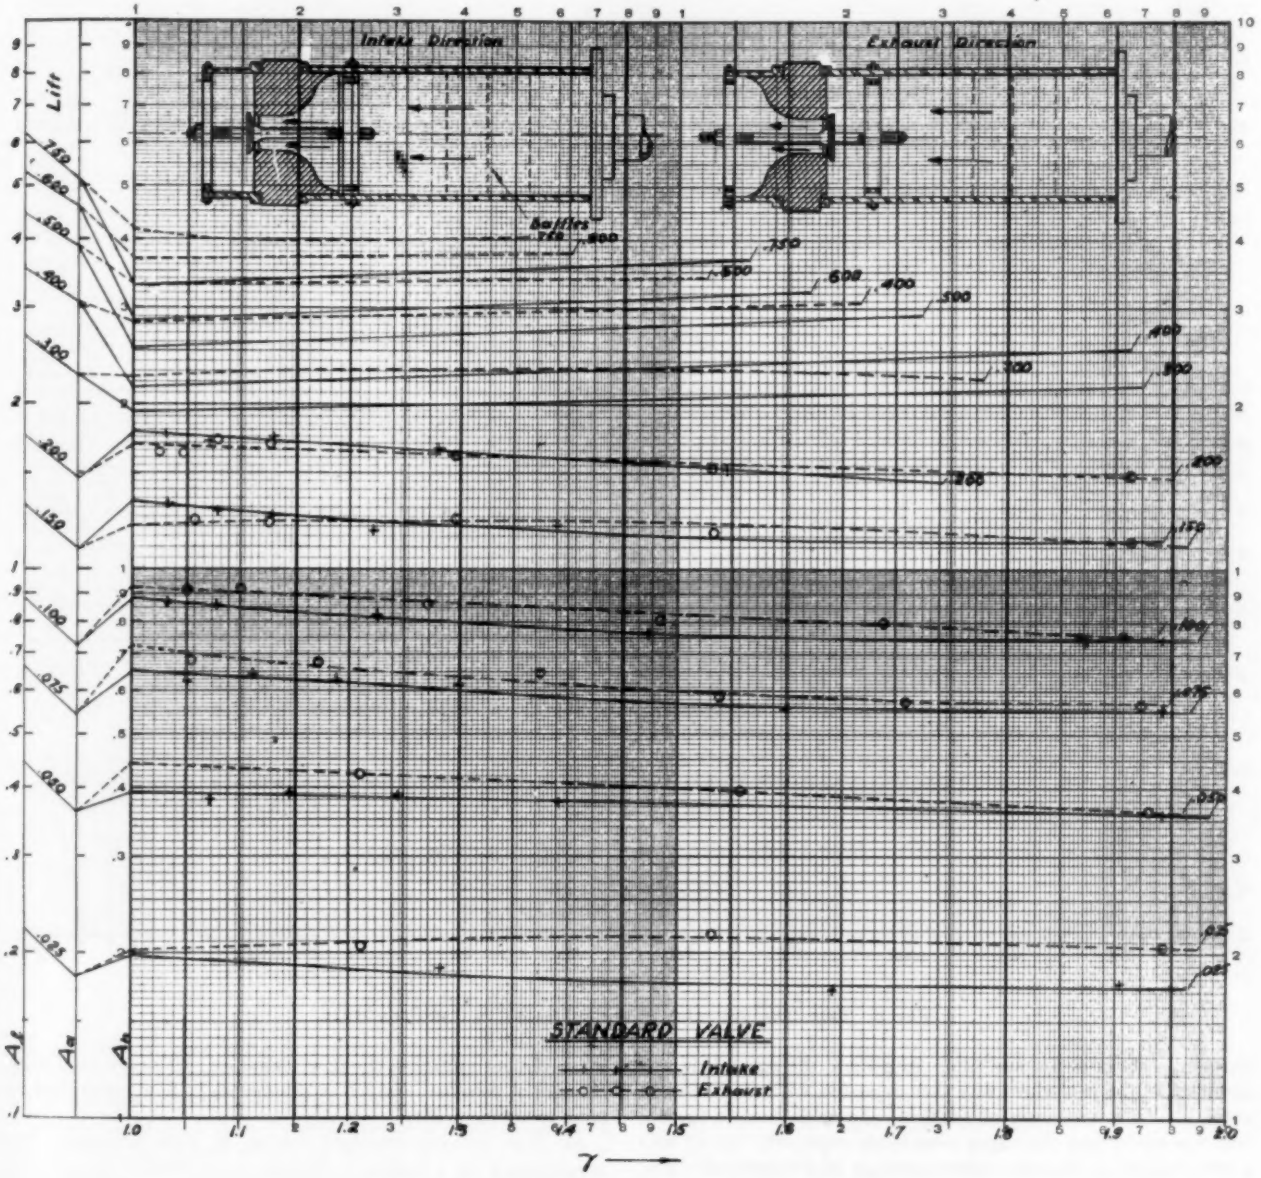

FIG. 5 TEST RESULTS—STANDARD VALVE IN MODEL

The general arrangement of the model for various tests is apparent in the individual sketches (Figs. 5 to 11, incl.). Fig. 4 shows the standard-type valve in place for test of flow in the intake direction. The valve is carried in two light spiders, which are accurately machined to hold it central in the model. These spiders are so shaped as to have slight effect on the flow of air. The lift of the valve is set by means of a thread (20 per inch) on an extension stem. This thread having been checked for accuracy, it is used as a micrometer.

When a cylinder head is being used in test, this is bolted to the 9-in. cylinder as is done when making an actual engine as-

having a slope of 1:10 to a measured length of 19 in., then with vertical alcohol and mercury manometers. Alcohol was preferred to water for use in the manometers because of its superior meniscus.

CONDUCT OF TESTS

The test procedure consisted in establishing a valve lift, opening the throttle valve to a definite position, and allowing air to flow until steady conditions were established. Then a reading was taken and the throttle-valve opening altered. When a complete series of readings with various throttle openings was

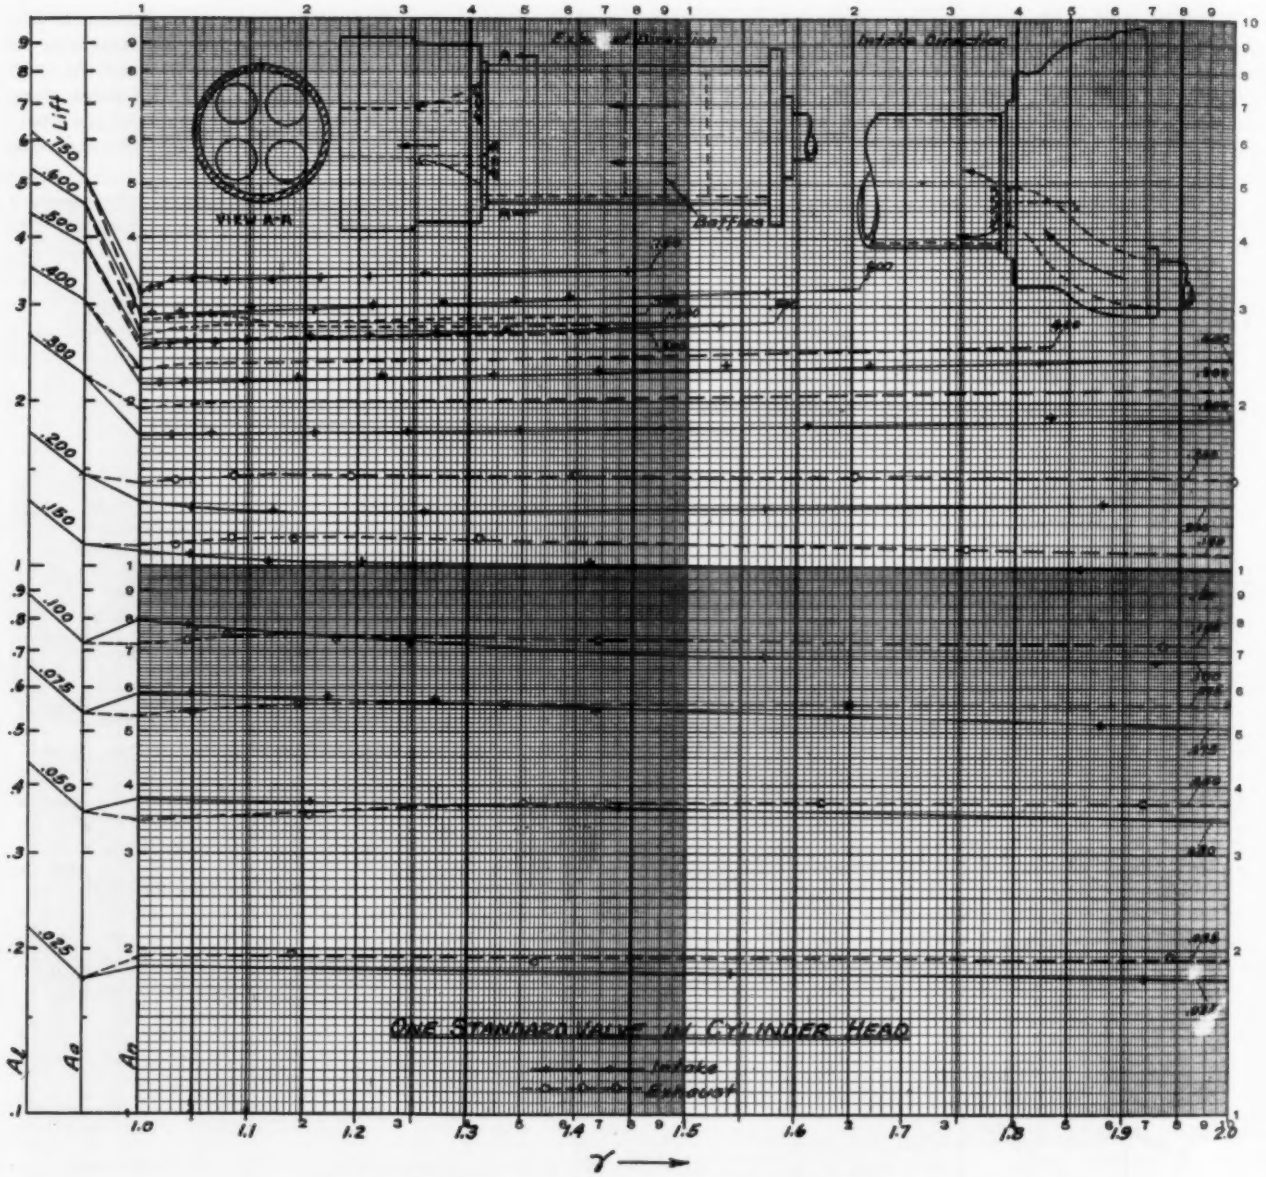

FIG. 6 TEST RESULTS—ONE STANDARD VALVE IN CYLINDER HEAD

finished, a check series was run. In general the agreement was excellent. The procedure was then repeated with an increased valve lift, to a maximum of 1.200 in. In some cases a further test was made with the valve completely removed. At all lifts a wide range of throttle valve openings was employed. The result of this was to extend the pressure ratios of tests with small lifts much beyond the range of ordinary application. Tests with large lifts were restricted by the capacity of the supply-pipe system. Nevertheless, these in all cases cover the generally useful range of pressures.

Readings of barometric pressure and of room temperature were made, in addition to the full series provided for in the test arrangement.

GENERAL OBSERVATIONS ON TESTS

Noteworthy differences were found in the behavior of the special "tulip" and "drop" types of valve on test, as compared with that of the standard valves. These took the form (1) of sharp discontinuities in the flow resistance, with only very slight changes of pressure, and (2) of differences in flow manifested by noise or by instability.

Air flow through standard valves, in both directions, was accompanied by a hissing or rushing sound which changed only in degree as the amount of air flowing and the pressure head increased. No abrupt changes of resistance or of flow characteristics were noticeable at any time.

The special valves in the majority of tests acted similarly, that is, no unusual sound or other behavior was noticeable. However, at points where instability of flow appeared, the other peculiarities in general developed also. The change in resistance was very abrupt and amounted to as much as 4 in. of mercury with an extremely slight difference of flow. The change of resistance was in the direction of a decrease with increasing flow. Hence sometimes actually less pressure drop was required for a large flow than for a smaller one. This effect was most noticeable with intermediate valve openings and in the exhaust direc-

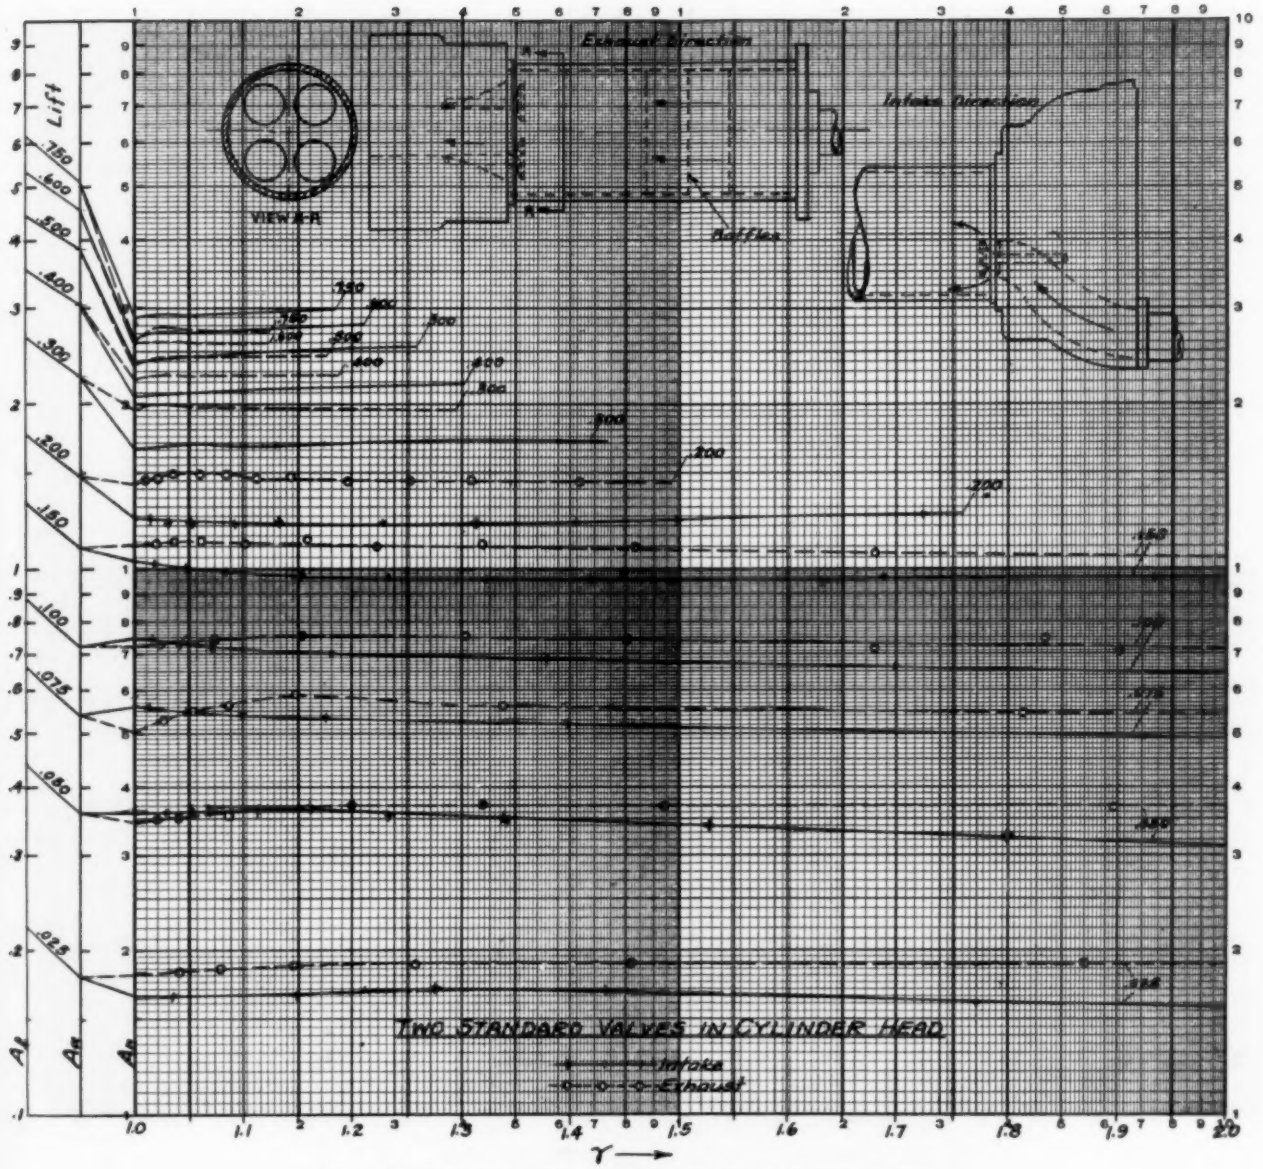

FIG. 7 TEST RESULTS—TWO STANDARD VALVES IN CYLINDER HEAD

tion of flow. In one instance the flow appeared to fluctuate back and forth between the two types in an interval of about 1.5 sec., thus rendering readings impossible.

An extremely loud, high-pitched whistle was associated with the discontinuity above described, though it did not appear in every instance. This whistle occurred only in the intake direction of flow, and was accompanied by only slight pressure fluctuation; often no noticeable fluctuation at all. The whistle occurred only at some pressures in a series with a fixed valve opening, starting and stopping once or twice during the series. Sometimes it would begin and continue for three or four consecutive readings, and then stop with no noticeable change in resistance or flow.

Another type of instability was seen in some cases with small openings. The flow of air instead of being uniform around the periphery of the valve was concentrated at one side. It might also be subject to fluttering, the flow shifting about the sides of the valve several times in a second. The pressure changes associated with this action were slight.

Further mention of these observations will be made in reference to particular tests.

CALCULATION OF RESULTS

The calculation of a test consists essentially of three steps; namely,

1 Computation of air weight from flow readings = G
2 Computation of theoretical discharge through the known area of valve opening under test conditions = (G_{th})
3 Computation of $\mu = G/G_{th}$.

The type of flow formula given by Equation [3] is suited to the flow-meter calculation. For this case the following constants are to be entered:

$$A = \frac{\pi}{4}\frac{(3)^2}{144} = 0.0492 \text{ sq. ft.}$$

$$\mu = 0.985.$$

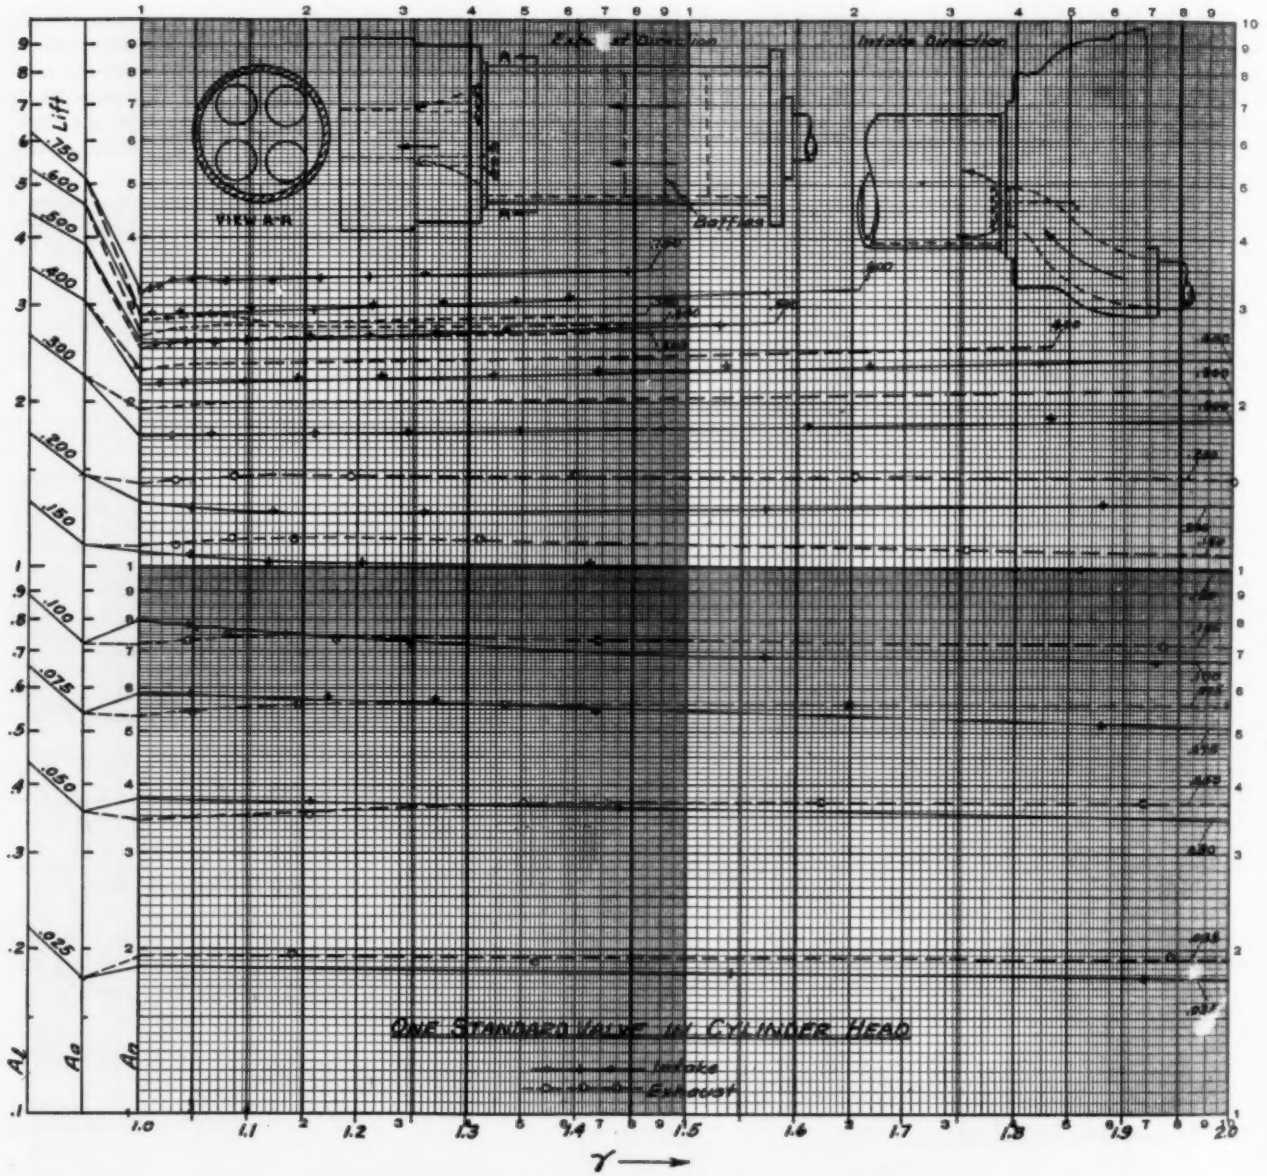

FIG. 6 TEST RESULTS—ONE STANDARD VALVE IN CYLINDER HEAD

finished, a check series was run. In general the agreement was excellent. The procedure was then repeated with an increased valve lift, to a maximum of 1.200 in. In some cases a further test was made with the valve completely removed. At all lifts a wide range of throttle valve openings was employed. The result of this was to extend the pressure ratios of tests with small lifts much beyond the range of ordinary application. Tests with large lifts were restricted by the capacity of the supply-pipe system. Nevertheless, these in all cases cover the generally useful range of pressures.

Readings of barometric pressure and of room temperature were made, in addition to the full series provided for in the test arrangement.

GENERAL OBSERVATIONS ON TESTS

tion of flow. In one instance the flow appeared to fluctuate back and forth between the two types in an interval of about 1.5 sec., thus rendering readings impossible.

An extremely loud, high-pitched whistle was associated with the discontinuity above described, though it did not appear in every instance. This whistle occurred only in the intake direction of flow, and was accompanied by only slight pressure fluctuation; often no noticeable fluctuation at all. The whistle occurred only at some pressures in a series with a fixed valve opening, starting and stopping once or twice during the series. Sometimes it would begin and continue for three or four consecutive readings, and then stop with no noticeable change in resistance or flow.

Another type of instability was seen in some cases with small openings. The flow of air instead of being uniform around the periphery of the valve was concentrated at one side. It might also be subject to fluttering, the flow shifting about the sides of the valve several times in a second. The pressure changes associated with this action were slight.

Further mention of these observations will be made in reference to particular tests.

CALCULATION OF RESULTS

The calculation of a test consists essentially of three steps; namely,

1 Computation of air weight from flow readings = G
2 Computation of theoretical discharge through the known area of valve opening under test conditions = (G_{th})
3 Computation of $\mu = G/G_{th}$.

The type of flow formula given by Equation [3] is suited to the flow-meter calculation. For this case the following constants are to be entered:

$$A = \frac{\pi (3)^2}{4\ 144} = 0.0492 \text{ sq. ft.}$$

$$\mu = 0.985.$$

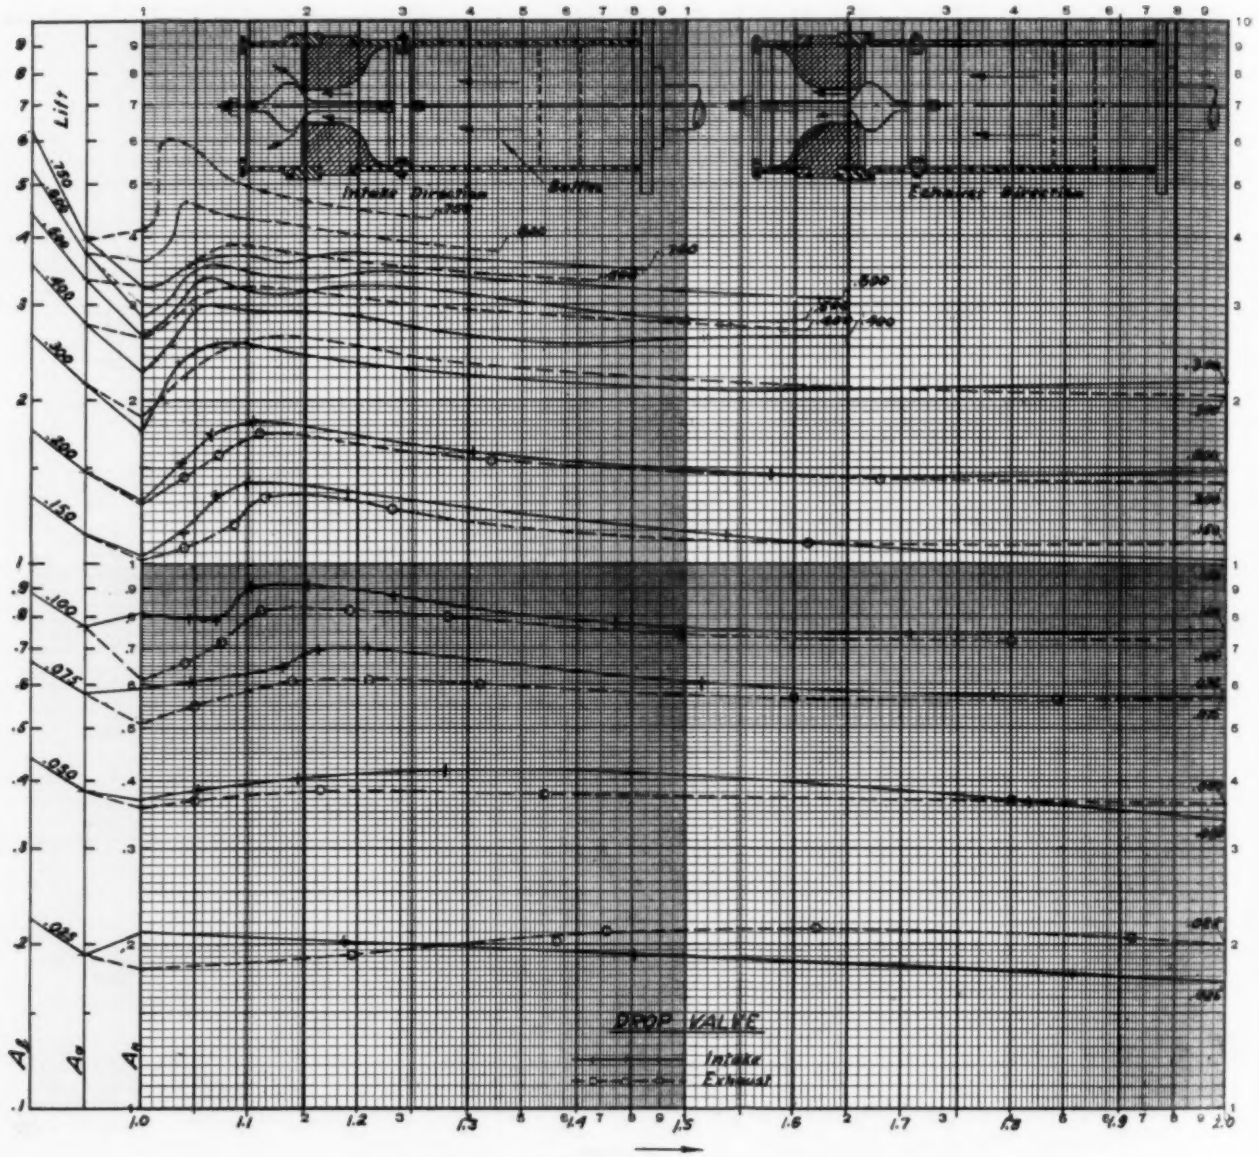

FIG. 8 TEST RESULTS—"DROP" VALVE IN MODEL

Z = correction factor for velocity of approach

$$= \sqrt{1 - \left(\frac{9}{3}\right)^4 \cdot \left(\frac{P_2}{P_1}\right)^{2/K}}$$

= 1.006 approximately.

The flow-meter equation then takes the form:

$$G = 7.65 \sqrt{\frac{\Delta P \cdot P_2}{T_{D1}}} \text{ lb. per sec.} \quad [6]$$

in which ΔP and P_2 are in lb. per sq. in.

Following some early difficulties with moisture, attention was given to the possible effects of humidity. A considerable amount of condensed water having been removed from the air after compression, its humidity was somewhat below normal, averaging less than 50 per cent. Check calculations showed that Moss's equations for "normal air" could be used with a maximum error of about 0.3 per cent, and this was considered satisfactory. Equation [6], based on constants for normal air, was used without further correction.

Computation of theoretical flow through the valve was made, using one or the other of the following equations:

When $P_a > 0.53 P_3$,

$$G_{th} = 5.37 A_a \sqrt{\rho_3 H \left[1 - \frac{3}{2K}\frac{H}{P_3}\right]} \text{ lb. per sec.} \quad [7]$$

When $P_a < 0.53 P_3$,

$$G_{th} = 0.325 A_a \sqrt{P_3 \rho_3} \text{ lb. per sec.} \quad [8]$$

in which:

P_3 = pressure before valve, lb. per sq. in. abs.
ρ_3 = density of air before valve, lb. per cu. ft.
P_a = atmospheric pressure, lb. per sq. in. abs.
$H = P_3 - P_a$ = gage pressure before valve, lb. per sq. in.

Equation [7] is derived from the expanded form of the thermodynamic equation of flow, given for normal air as follows:[3]

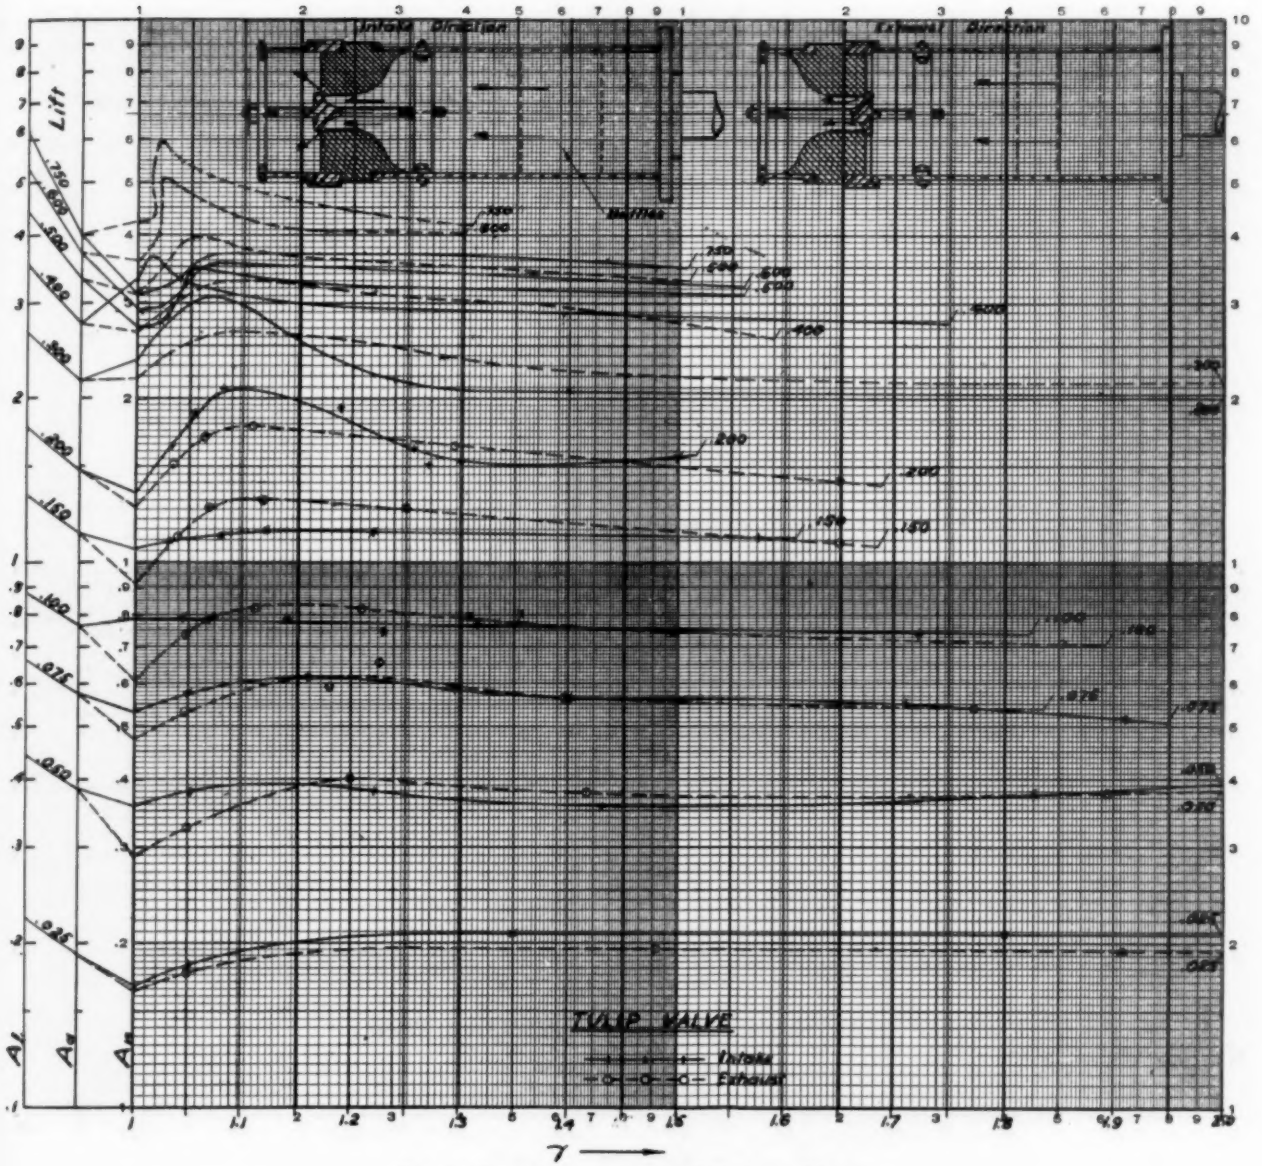

FIG. 9 TEST RESULTS—"TULIP" VALVE IN MODEL

$$G = 158.17A\sqrt{\frac{(P_1 - P_2)[P_2 - 0.0755(P_1 - P_2)]}{T_{D1}}} \quad \ldots [9]$$

while Equation [8], in which flow depends upon initial conditions only, has the form

$$G = 76.367\,\frac{A\mu P_1}{\sqrt{T_{D1}}} \quad \ldots [10]$$

The result of each test is expressible in the term $\mu = G/G\text{th}$. It was found that much labor could be saved by combining Equation [6] with Equations [7] and [8], respectively, in the forms

$$\mu = \frac{G}{G_{th}} = \frac{6.97}{A}\sqrt{\frac{\Delta P}{H\left[1 - \frac{3}{2K}\frac{H}{P_3}\right]}\,\frac{T_{D2}}{T_{D1}}\,\frac{P_2}{P_3}} \quad \ldots [11]$$

when $P_a > 0.53P_3$, and

$$\mu = \frac{G}{G_{th}} = \frac{14.31}{A}\sqrt{\frac{\Delta P}{P_3}\cdot\frac{T_{D2}}{T_{D1}}\cdot\frac{P_2}{P_3}} \quad \ldots [12]$$

when $P_a < 0.53P_3$.

Further simplification was attained by the approximations:

$$\frac{T_{D2}}{T_{D1}} = 1 \text{ (error negligible)}$$

and

$$\frac{P_2}{P_3} = \text{(error in } \mu \leqq 1 \text{ per cent)}$$

The equations then reduce to the forms:

When $P_a > 0.53P_3$

$$\mu = \frac{6.97}{A}\sqrt{\frac{\Delta P}{H\left[1 - \frac{3}{2K}\frac{H}{P_3}\right]}} \quad \ldots [13]$$

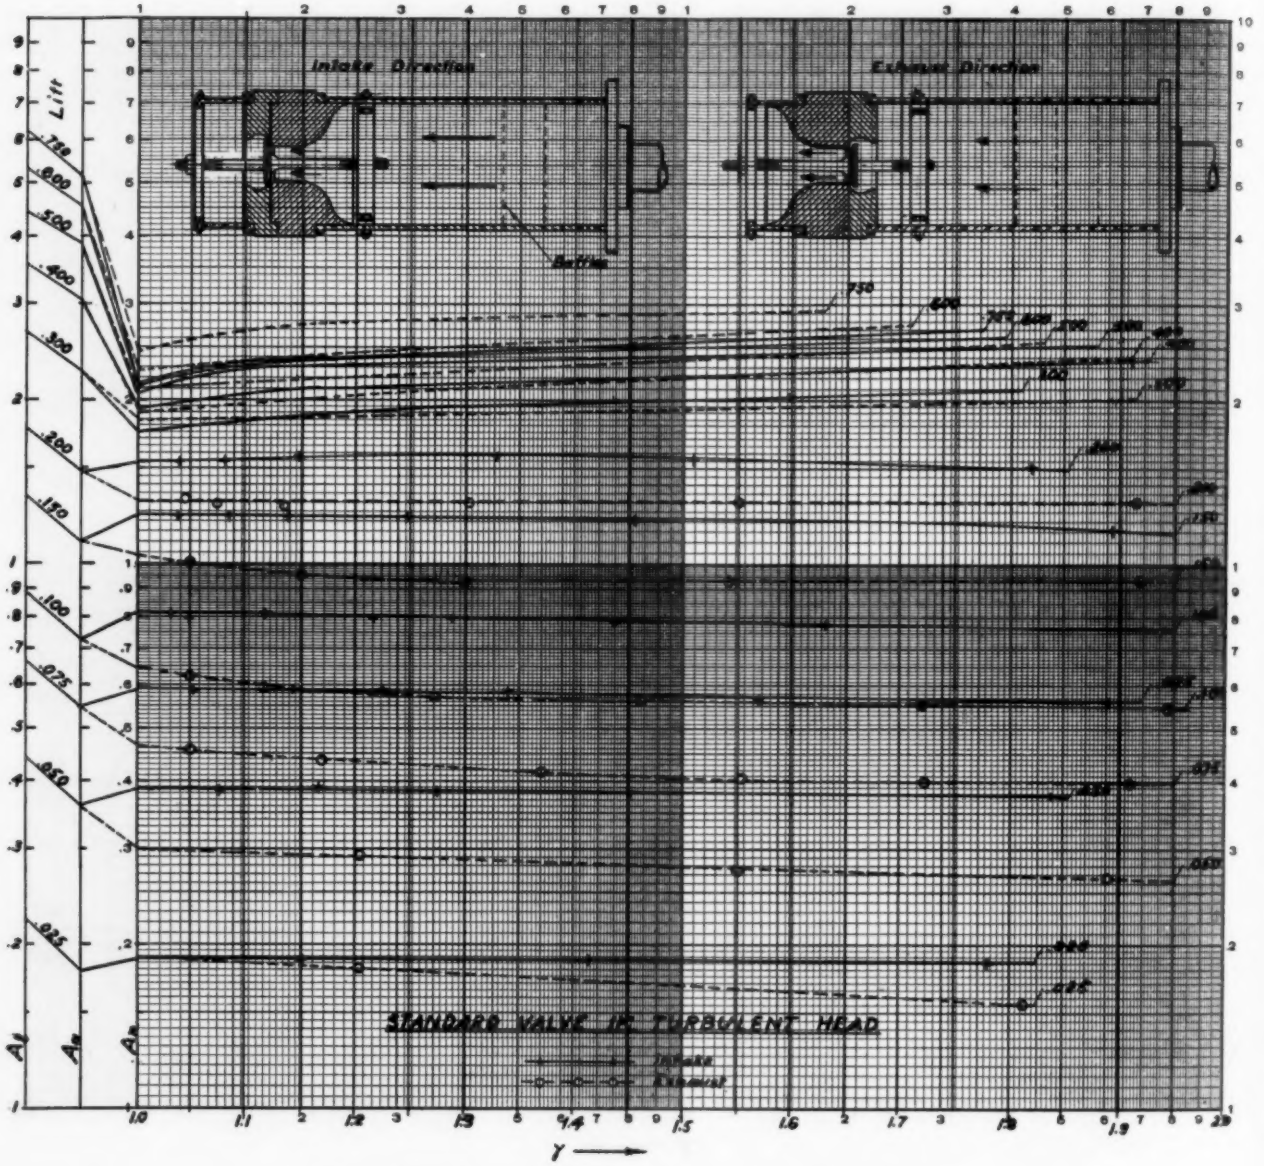

FIG. 10 TEST RESULTS—STANDARD VALVE IN TURBULENT HEAD

when $P_a < 0.53P_1$,

$$\mu = \frac{14.31}{A}\sqrt{\frac{\Delta P}{P_1}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [14]$$

These forms were accepted as being sufficiently close for the purposes of this work.

ESTIMATE OF ERRORS AND PRECISION OF RESULTS

Errors contributing to inaccuracy of the results are of two kinds: those due to approximations in the formulas, and those due to inaccuracies of observations.

Errors in Formulas and Method of Calculation

In this class are to be considered:

1 Flow-meter calculation, Equation [3]. Moss's curves indicate maximum error within the range of application = ±0.2 per cent
2 Neglect of humidity. Check calculations showed maximum error in density about ±0.6 per cent; in μ, ±0.3 per cent
3 Equations [7] and [8]. Negligible errors
4 Neglect of velocity of approach to valve. Calculated 0.35 per cent, error for worst case
5 Use of simplified formulas, Equations [13] and [14]. Maximum about 1.0 per cent.

The total effect of these possible errors in calculation methods is probably not over 1.5 per cent and averages perhaps 1 per cent.

Errors of Observation

1 Setting of Valves. Accuracy of valve lift is affected by the following conditions:
   (*a*) Setting to correct opening
   (*b*) Movement of valve after setting
   (*c*) Eccentricity of valves with respect to seat.
2 Reading gages and manometers.
3 Changing of air pressure while readings were being taken.

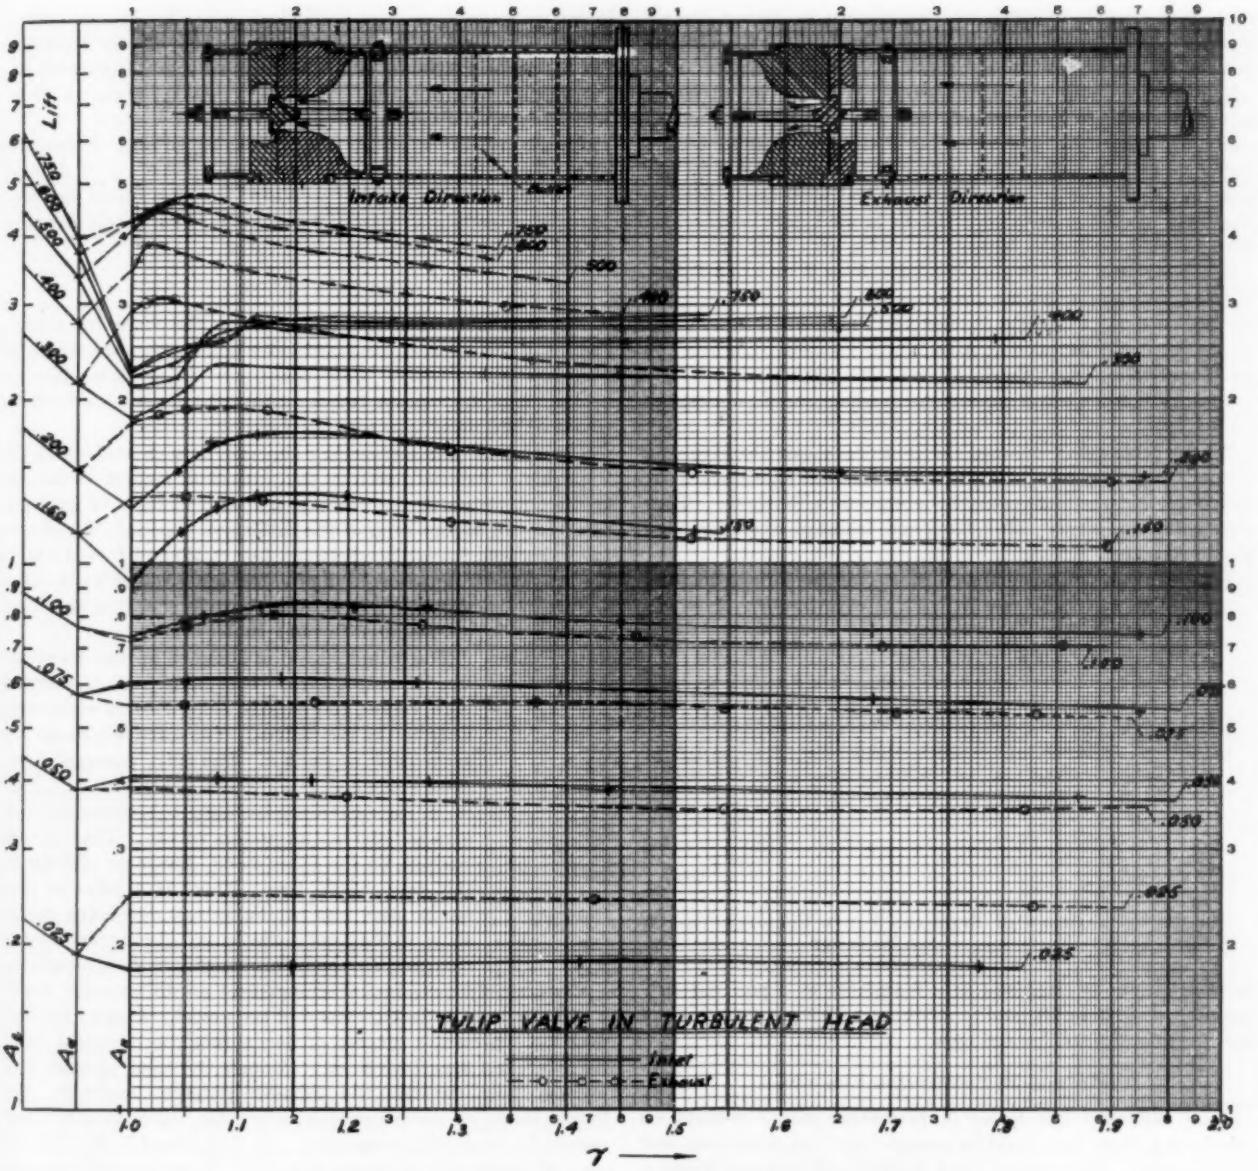

FIG. 11 TEST RESULTS—"TULIP" VALVE IN TURBULENT HEAD

1 *Setting of Valves.* In the test of the valves in the cylinder head the valves could be set accurately with a dial indicator placed against the end of the stem. The settings were checked frequently during each run, as pressure against the valve increased, and any longitudinal movement was corrected by moving the valve back to its correct position by means of a screw against the end of the valve stem. For openings above 0.200 in. the opening was obtained by setting this screw against the stem and giving it the proper number of turns. Then the indicator was placed in position to register any longitudinal movement of the valve. The screws were threaded with 20 threads per inch so that one turn of the screw opened the valve 0.050 in.

The valves were observed to move longitudinally from 0.001 to 0.003 in., but this movement was corrected by resetting the valve each time the pressure was changed. Movement of the valve occurred only at small openings (0.025 to 0.300 in.) where the pressure went up to 20 lb. per sq. in. or more.

Under these conditions, the error was not over 0.001 in. at the time of observation. At an opening of 0.025 in. this error is 4 per cent; at lifts of 0.100 in. and over, 1 per cent or less.

When valves were tested in the wooden models, the valve lift was obtained by giving the valve a certain number of turns, after it had been closed on its seat, to give the desired opening. The valve stems were threaded with 20 threads per inch and screwed into the spider which held the valve in place.

A slight looseness in the fit of the thread in the spider permitted a longitudinal movement of 0.003 to 0.005 in. when pressure came against the valve, that is, at small valve openings where the pressure went up to 25 lb. per sq. in. or more. The movement of the valve in this case could not be measured conveniently by the dial indicator because the airstream came out all around the stem and the indicator would be moved by it.

Inaccuracy of the seat in the wooden model and perhaps a slight eccentricity of the valve with respect to the seat could be a source of error in the valve setting and in affecting the direction of the air stream. The effects would be negligible for large

valve lifts. Some difficulty was experienced in getting the air to flow out uniformly around the entire circumference of the valve at small valve lifts.

2 *Reading Gages and Manometers.* Pressures in all cases, except where there was unsteady flow and fluctuation, could be easily and accurately read by means of the alcohol and mercury manometers. In many cases where the flow was steady the pressures would remain quite constant and were easily read to $^1/_{32}$ in. of alcohol or mercury. Leaks around gage connections were guarded against by frequently testing with soap suds.

3 *Changing of Air Pressure While Readings Were Being Taken.* There were times when the pressures would slowly change and one pressure, say P_1, might change 1 or 2 per cent before P_2 and $(P_1 - P_2)$ could be taken. Attempts were made, however, to get these readings simultaneously or as quickly as possible.

Errors due to incorrect manometer readings should not exceed 1.5 per cent.

Where pressures were read on Bourdon gages the errors in readings may be greater. These gages were not highly sensitive, and only fair readings could be obtained with them. They were calibrated every other day, and readings were corrected when necessary.

Total of Errors. The combined effect of errors in formulas and in observations is estimated at a maximum of 5 per cent to 7 per cent at 0.025 in lift, and a maximum of 2.5 per cent to 3 per cent for lifts of 0.100 in. and over.

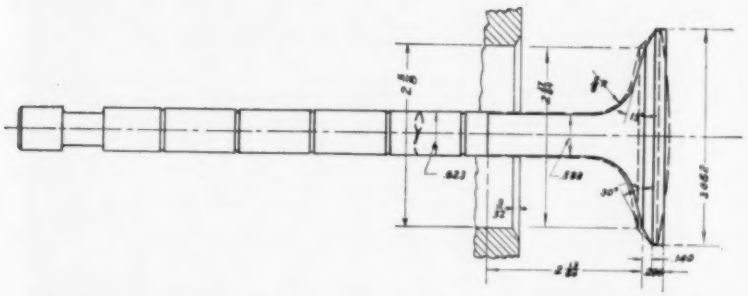

FIG. 12 COMPARISON OF STANDARD VALVE USED FOR TEST WITH $2^3/_8$-IN. S.A.E. VALVE

METHOD OF PRESENTING RESULTS

Some difficulty was found in presenting rather voluminous results in a form that could be compact and yet would not lead to confusion. The method used is not in all respects satisfactory, but it does permit a fair comparison of valve performance to be gained by inspection, and also to enable numerical data for individual cases to be read by simple graphical means. Figs. 5 to 11, inclusive, give the results of tests of various arrangements, the inlet and exhaust directions of flow being shown on the same diagram.

The vertical scale is logarithmic and refers to valve area (sq. in.) in various aspects. The abscissas give the ratio of pressures $\gamma = P_2/P_a$, before and after the valve, and cover values of this ratio between 1 and 2.

Three equal scales of area are given at the left. On the first, the value of A_l is marked for each valve lift tested. The second scale gives the corresponding actual minimum area A_a. These quantities are both established by geometrical relations, and hence are identical for either direction of flow.

Equivalent orifice areas $A_n = \mu A_a$ are plotted on the diagram proper. The variations in μ are reflected in the vertical displacement of individual points, where plotted, and of the curves drawn through them. The latter are in all cases extrapolated to the limit $\gamma = 1$, and tied in by tracers to the A_a-scale. It was found inexpedient to show individual points for lifts exceeding 0.200 in. on account of crowding. Probably without exception the fitting of curves to points is progressively better with increasing lift over 0.200 in. Valve lifts over 0.750 in. ($L/D = 0.266$) are not plotted here.

Certain properties of the diagram are apparent. Where the tracer between A_a- and A_n-scales slopes upward, $\mu > 1$, and vice versa. The value of $\mu = A_n/A_a$ may be found for any point by extending a horizontal line from A_a-scale and stepping off log μ from the figure; similarly for $\Psi = A_n/A_l$.

RESULTS OF TESTS

Fig. 5 shows a test of a standard valve in the concentric model. Details of the so-called standard valve and its port are shown in Fig. 12. For reference only, this latter figure shows also in broken lines the nearest corresponding S.A.E. standard valve. (None of the latter type were used in test.)

This test is characterized by superior flow characteristics in the exhaust direction, and by the absence of sudden variations or discontinuities in the coefficient μ with changes of pressure ratio γ. An abrupt drop of the coefficient, especially for the intake direction, takes place between $L = 0.200$ and $L = 0.300$.

Figs. 6 and 7 represent tests of valves identical with the valve shown in Fig. 5, with the difference that here they are mounted in the cylinder head.

The cylinder head is designed for two inlet and two exhaust valves. One inlet passage supplies both valves, the passage being located symmetrically to the two valves. The exhaust-passage arrangement is similar. The inlet passage, however, is shaped as a diffuser. The area is 7.1 sq. in. at the entrance, expanding to a combined port area of 10.8 sq. in. at the valves. The exhaust passage, on the other hand, contracts slightly in the direction of flow. There is a total of 10.8 sq. in. port area at the valves, decreasing to 9.6 sq. in. at the point of discharge. In the test the discharge at this point was directly to the atmosphere.

Certain differences in the arrangement are to be noted where a cylinder head is tested instead of the model. Firstly, the test does not represent a reversal of flow through an identical path, for inlet flow was tested only through the inlet passage and exhaust flow through the exhaust passage. Secondly, the measurement of static pressure before the valve in inlet flow required a modified arrangement. In Figs. 6 and 7 the entrance pipe at the right is the flow-meter tube. Both tube and passage are of 3 in. diameter. The desired pressure before the valve is total pressure. This is taken as P_1 (pressure before the flow meter); the slight flow resistance in the short 3-in. tube is neglected.

Comparing Figs. 6 and 7 with Fig. 5, we find (1) a slight decrease in efficiency for inlet flow and (2) a large decrease for exhaust flow for valves mounted in the cylinder head. This is shown by the data in Table 2, taken from the diagrams. Like Fig. 5 these diagrams show no sharp discontinuities with pressure changes.

TABLE 2 STANDARD VALVES, IN MODEL AND IN CYLINDER HEAD. VALUES OF A_n

(Valve lift = 0.600 in.; pressure ratio $\gamma = 1.05$)

	Inlet	Exhaust
One valve in model, sq. in.	2.84	3.70
One valve in cylinder head, sq. in.	2.90	2.74
Two valves in cylinder head, sq. in.	2.71	2.74

Figs. 8 and 9 give the results with so-called "drop" and "tulip" types of valve, respectively. These models represent an effort to reduce resistance by giving the valve a favorable shape,

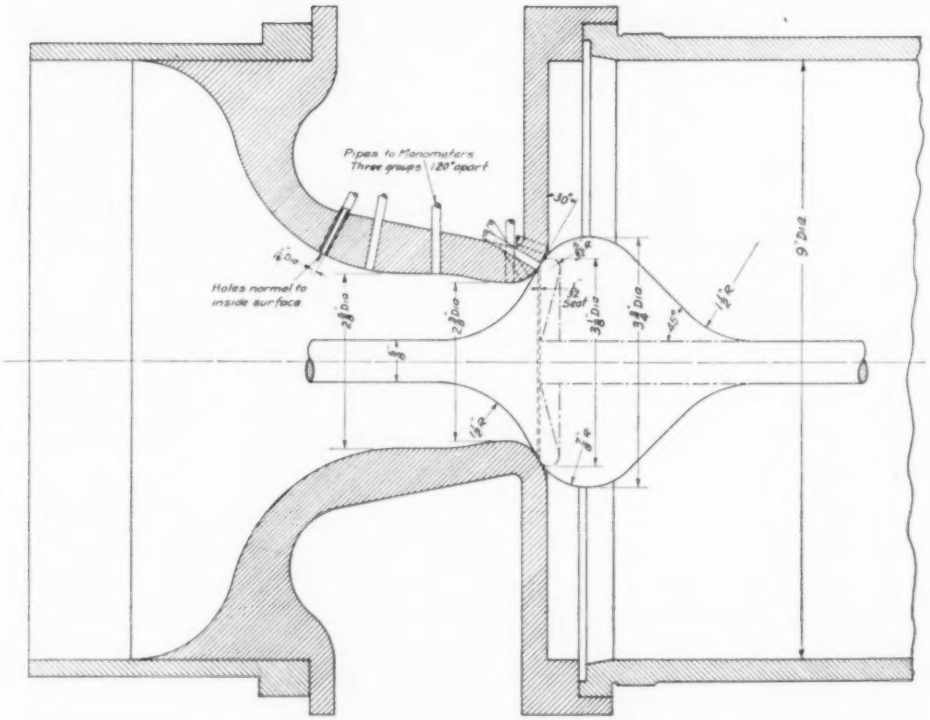

FIG. 13 TEST MOUNTING FOR "DROP" AND "TULIP" VALVES

regardless of the suitability of the valve in practice. For purposes of comparison the valve mean seat diameter D (= 2.82 in.) and the cone seat angle (= 30 deg.) are the same in both as in the standard valve. (See Fig. 12.) In addition to the special valve shape, the valve port and seat are modified also. The effect is to produce an expanding flow area extending from the minimum section in either direction. The increase is of course much less gradual for inlet flow than for exhaust; this seems to be unavoidable. In this respect the "drop" type appears somewhat superior, but the valve of Fig. 9 is a closer approximation to practical needs.

Comparing the test results, both differ substantially from those with the standard valve. We note (1) generally much higher values of A_a. These data show μ as high as 1.60 at the high point and Ψ in several cases above unity, (2) a large variation in the value of μ with change in γ. This variation of μ is accompanied by a discontinuity particularly in exhaust flow at large lifts. The curves of A_a show maxima which occur at decreasing values of γ as the lift L is increased. The general character of the inlet flow curves is similar to the exhaust curves, but the discontinuities are replaced by more gradual changes at all lifts.

The general results in Figs. 8 and 9 are very similar. Only at small lifts the "drop" valve appears superior.

Figs. 10 and 11 are for standard and tulip valves, respectively, mounted in a model cylinder head of a "turbulent" type. The valve pocket forms the combustion space, and opens on the cylinder proper immediately above the top position of the piston. Fig. 14 shows the shape of the pocket as tested with the two types of valve. It is apparent that resistance to flow in and out of the cylinder will be increased by such an arrangement. Furthermore, as the lift increases, a point is reached beyond which the section will decrease, and therefore resistance will become larger.

Inspection of the curves shows that the tulip valve greatly reduces resistance in exhaust flow, but has almost no effect in inlet flow. Inlet resistance is seriously increased as compared with the ordinary mounting without a pocket.

Figs. 15 to 20, inclusive, summarize the data of Figs. 5 to 11, inclusive, in a manner which permits a more direct comparison between various valve performances, and which is suitable for design application. For this purpose it was necessary to make an arbitrary assumption of a representative value for γ, the pressure ratio. This is taken as 1.05 for all these curves, corresponding to a pressure drop in engine use of 0.700 lb. per sq. in. for intake flow, or of 0.735 lb. per sq. in. for exhaust flow. The effect of operation with other values of γ is slight for standard types of valve, but may be considerable for special valves.

These diagrams are non-dimensional, permitting their application to any size of valve. The abscissa is L/D. The ordinate is area in various aspects, referred to $\pi D^2/4$ as unity. The quantities plotted include A_l, A_a, and A_s. To another scale the variation of Ψ is plotted also.

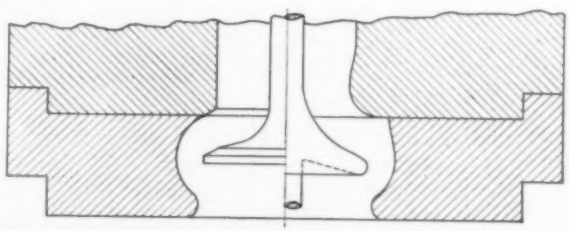

FIG. 14 STANDARD AND "TULIP" VALVES IN TURBULENT HEAD

Fig. 15 compares standard valves in inlet flow tested in the model and in the cylinder head. Fig. 16 makes a similar comparison for exhaust valves. The model test is seen to be a fair guide to performance in actual mounting in the case of the intake valves, but very misleading in the case of the exhaust valves.

Figs. 17 and 18 compare "tulip" and "drop" types for inlet and exhaust flow. A striking feature of Fig. 18 especially is that while the actual section A_a of the special valves is less, the equivalent orifice is considerably greater than for the standard valve.

Figs. 19 and 20 compare results obtained using the turbulent head with the performance of the standard valves in the simple model. By using the tulip type of valve in the turbulent head, good performance is attained in exhaust flow, but intake resistance is comparatively large and not much improved with the special valve.

SPECIAL TEST OF TULIP-TYPE VALVE

After these tests an attempt was made to explore flow conditions in the restricted section of the valve by observing static pressure at various points in the path. Pressure connections were made as indicated on Fig. 13. Care was taken to locate the

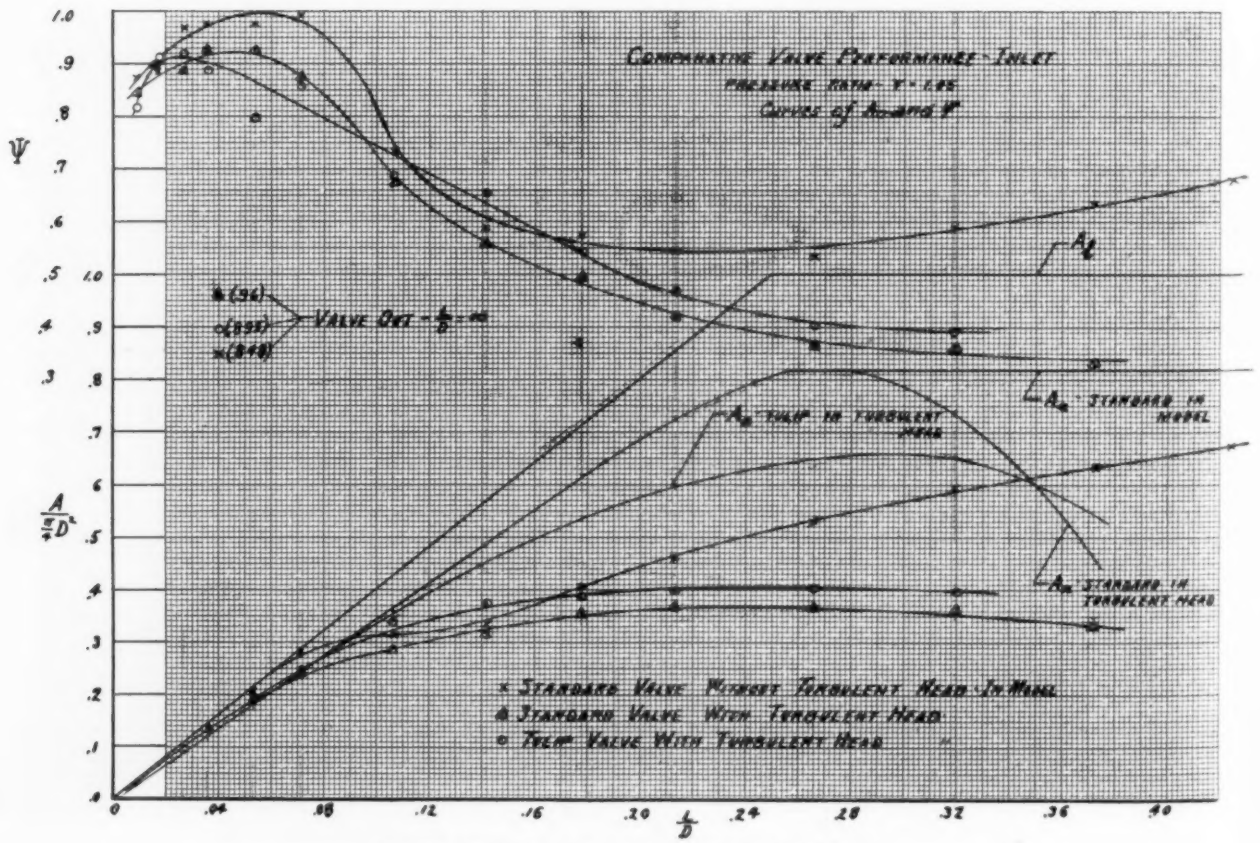

Fig. 20 Valves in "Turbulent" Head, Inlet Flow

holes normally to the surface, and to finish the edges smoothly. The model was then tested under some conditions identical to the original ones. The pressures at various points were observed in addition to other measurements taken as before. The purpose was to find, if possible, the location and cause of losses.

The results were in several respects unsatisfactory. The tests themselves were marred by violent instability when testing flow in the exhaust direction, at lifts of 0.300 in., 0.500 in., and 0.700 in. No readings could be taken with 0.500 in. lift. This model differed from the original in being made of metal whereas the first was of wood; this seems to be the only reason for the change in behavior, which was one of degree and not of kind. Also, extremely loud whistling occurred with inlet flow at several openings.

The connections as made failed to give satisfactory static-pressure readings. This was apparent when the sum of calculated velocity pressure plus observed static pressure in some cases exceeded P_3, the initial pressure.

No positive conclusions of value could be drawn from this test. The data were in some respects contradictory, and were unsatisfactory for analytical purposes. One fact of interest was that in several cases the velocity of the air exceeded that of sound in the expanding section of the path.

Comparison With the Results of Others

Efforts were made to establish a correct basis for comparing the present results with those of other experimenters. The comparison is not in all respects satisfactory because of differences in presentation of results, differences in types of valves and test methods, and lack of detail information, especially in the case of Nutting and Lewis.

Table 3 gives the particulars of four different types of valve and the kind of test arrangement used with each. A brief inspection will show that no two valves and test conditions are identical. The closest similarity is between the authors' standard valves ($\gamma = 1.25$) and Tanaka's 30-deg. valve ($\gamma = 1.245$).

In Fig. 21 the various results are placed upon a common basis. The abscissa is lift/port diameter, a different quantity from L/D as used elsewhere in the figures. The ordinate is coefficient of discharge based upon the area $\pi D_p L$, also a different quantity from that used elsewhere in the work.

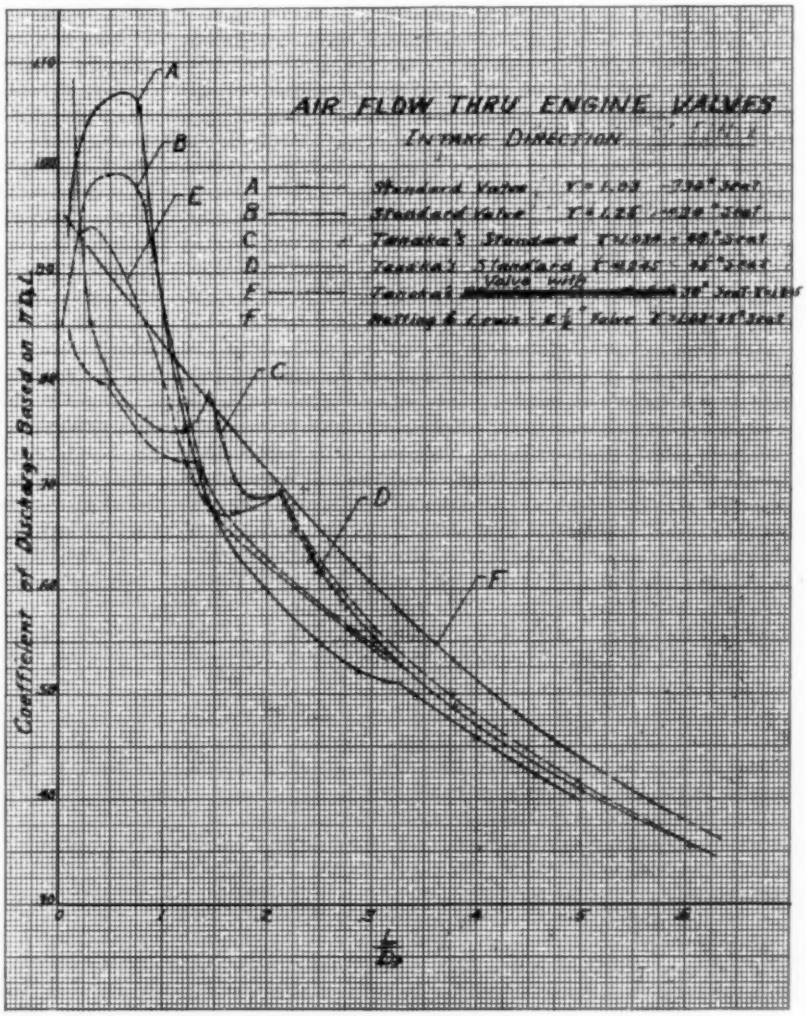

Fig. 21 Comparative Results for Flow Through Inlet Valves

Curves B and E represent results with the two valves above mentioned, which form the best available basis for comparing the present results with those of Tanaka. His results in terms of flow coefficient are available only for his standard 45-deg. valve. The corresponding figures for his 30-deg. valve were arrived at by assuming his W_∞ (flow weight with valve removed) to be the same for either valve, a justifiable assumption.

The agreement of the two curves is good except with small lifts; here precision is in no case so good as with larger lifts. The general shape of the curves is also very similar. In the absence of other opportunities for comparison, this agreement in the two curves is taken as a satisfactory but by no means positive check between the two series of experiments.

Nutting and Lewis' valve was similar to Tanaka's standard; the exact differences are unknown. But their results do not check those of Tanaka, and particularly fail to show the discontinuities which are a feature of Tanaka's curves. Tanaka's results are undoubtedly to be preferred on grounds of superior precision and completeness. There is no direct comparison between the present test and those of Nutting and Lewis.

Tanaka's available results with exhaust valves are quoted upon a relative basis (W/W_∞) which does not lend itself readily to comparison. No common basis for a check of results could be established. In view of this fact, and also because of other criticisms of Tanaka's exhaust-flow experiments, which will be

TABLE 3 COMPARATIVE VALVE DATA FROM INLET-VALVE TESTS

	Tanaka	Tanaka	Nutting and Lewis	Authors
Diameter of port, in.	2.60	2.60	2.50	2.625
Angle of seat, deg.	30	45	(45)[1]	30
Valve-head angle, deg.	0	0	..	15
Type of model	Concentric	Concentric	Cylinder head	Concentric
Approximate pressure ratio	1.245	1.034 & 1.245	1.03 (approx.)	1.03 & 1.25
Number of valves	1	1	2	1
Corners of valves and seat	Sharp	Sharp	(Sharp)[1]	Sharp
Type of flow	Continuous	Continuous	Continuous	Continuous

[1] Estimated from sketch.

discussed later, attempts at a comparison were abandoned. The work of Nutting and Lewis did not include exhaust-flow tests.

Discussion of Results

The value for design and other purposes of experimental results such as the present ones is predicated firstly on the precision of the results in themselves, and secondly on the influence which operating conditions may have upon their interpretation.

In the case of valve tests, conditions of application which must be taken into account include intermittent operation, and particulars of valve mounting and connecting passages. Differences in gas condition, as for hot exhaust gas, are adequately cared for by the proper use of flow equations and gas constants. On the other hand, when a special phenomenon is known to exist, such as the discontinuities found in the tests of special valves, the nature and effects of this condition must be fairly well understood if the data are to be applied with confidence.

Some facts bearing on the mounting of "standard type" valves were demonstrated. For inlet flow, the valve had nearly equal coefficients whether mounted in the model or in the cylinder head. Some loss of efficiency developed where both inlet valves were in use. This is attributed directly to friction loss in the somewhat narrow passage. The effect of inlet-valve mounting with this type of valve may they be disregarded unless the approach passage is unusually restricted in any way. Furthermore, the present tests in model and in cylinder head not only agree reasonably well among themselves, but they serve as a check upon Tanaka's model test of a similar valve. Doubtless an equal valuation is to be placed on his tests with all types. Hence, so far as Tanaka's results for inlet valves may be placed on an absolute basis instead of the inconvenient relative basis which he employs, they should be used with confidence. His results are available for a great variety of detail modifications. A design basis for inlet valves, therefore, is to be found in Figs. 5, 6, 7, 15, and 21 and in the data of Tanaka. An allowance of 5 per cent efficiency loss for cylinder-head mounting as compared with a model test should be sufficient, unless the arrangement is peculiarly unfavorable. The assumption of similar behavior for geometrically similar valves will be slightly too favorable for smaller valves and the reverse for larger valves.

Exhaust-valve conditions are quite different. Fig. 16 shows the remarkable loss of efficiency for valves mounted in the cylinder head as compared with the valve in the model. The reason is apparent in view of the other results found. In reversed flow, the rounded mouthpiece of the model acts as a diffuser, and artificially cuts resistance much below what may be expected where no such provision is specially made. The model as constructed is far from an ideal diffuser for exhaust flow, yet it is probably more favorable in this respect than any practical design could be. Therefore the model test of Fig. 5 (exhaust direction) is thought to be quite misleading. This criticism applies with the same force to all the results of Tanaka on exhaust valves. As his model is sketched, it will act in reverse flow as an even better diffuser than did the present model. Tanaka's relative basis for showing his results (W/W_∞) is even more unsatisfactory for exhaust than for inlet valves, for with valve removed his model is certainly an excellent diffuser. No satisfactory basis for design is therefore to be found in this phase of his work. The data of Figs. 6 and 7 and the curves for "valves in cylinder head," Fig. 16, are more reliable and should be only slightly different if, for example, a 45-deg. valve were substituted; this much may be deduced from the relative values of Tanaka's original curves. But in the application of exhaust-valve data, the possible effect of the exhaust-passage shape must be considered. If this can be given a gradually expanding section, the result may be highly favorable. The effect may be evaluated only by test. In any case the character of the passage has a major effect on exhaust-valve operation, but only a minor effect on the operation of inlet valves.

In considering the effect of intermittent action as in engine operation, the length of intake and exhaust passages is important. If intake and outlet were direct to the atmosphere without intervening columns of air or gas, flow during intermittent operation should differ very little at any instant from steady flow at an equal lift. The air or gas is quiet up to the point of restriction at the valve. There is little or no mass of fluid to be accelerated, and the flow may assume any rate instantaneously. Where long passages lead to the valves, the column of gas in the passage is alternately accelerated and retarded, and the effect on performance may be considerable. Of such inertia effects it is known that the net result may be favorable, as, for example, in the "ramming" effect of a long intake pipe. No means is here offered for evaluating such effects; any proposed method should be checked against suction indicator cards, and data for such a comparison are not now at hand. Until new data bearing on the question may become available, it is recommended that flow during the opening and closing of the valve be treated as similar to continuous flow at the same point of lift. Where passages are long the criterion is unreliable.

The two special types of valve gave similar results; we shall refer to the "tulip" type which approaches a practicable shape. For intake flow this type showed a good improvement over the standard valve, amounting to between 10 and 50 per cent at operating lifts. This is probably near the limit of what can be made good in practice, for the limitations to the diffuser principle in inlet flow are obvious.

In exhaust flow the gains are greater and more consistent. Also the possibilities of a further development may be considered more promising, for there is less to limit the shaping of the opening past the exhaust valve and port into a good expanding section.

Discontinuities of the orifice coefficient as the pressure ratio increases are a disturbing factor in interpreting and applying data, as are also such instabilities as resulted in loud whistling with some flow conditions. There can, therefore, be less certainty in using for design the data which were obtained than was the case with standard valves. To these considerations must be added the fact that modification to the "tulip" valve would be required to make it practical, resulting in some change of behavior.

The peculiarities of the tulip and drop valves remain for the present without full explanation. The sudden change of μ with increasing flow is doubtless due to a shift in the type of flow, particularly a change of the point at which the high-velocity airstream leaves the wall surface. For example, considering Fig. 13 with flow in the exhaust direction, the lower μ may obtain when diffuser action ends at the termination of the $2^3/_8$ in. diameter, and the higher μ when it continues to the end of the $2^5/_8$ in. diameter. If so, the discontinuity would be removed if a cone of proper angle were substituted for the irregular curve. Also higher efficiency should develop if the diffusers were made longer. Photographic study of the flow, as used by Tanaka, is the best attack on this problem.

Of the "tulip"-type valve with specially formed port, it can be said in general that it is promising for either inlet or exhaust application. The prospective gain over the conventional valve is so large that a valuable reduction in size of valves and gear may be anticipated, or in some cases the use of one valve instead of two. It is not thought that the present data are sufficient for design. Continuation of development is needed both in the valve itself and in experimental engine application.

The diffuser principle has had two forms of application in the experiments: (1) Locally at the valve head, over a path of perhaps 2 in. (2) In the connecting passage, say over a path of 6 to 12 in. above the valve. The former was effective in the tests of the "tulip" and "drop" valves, and showed its value for both inlet and exhaust flow. The second was tried in the inlet-valve test of the cylinder head, where the passage expanded from the cylinder-head entrance to the port openings. Here it failed to show any advantages. In exhaust flow, on the other hand, the model as before stated acted as a diffuser and caused a major improvement in valve performance. Since both types of diffuser are applicable to exhaust flow, they should preferably be combined; that is to say, the entire exhaust passage from the restriction under the seat to the point of release into a receiver or to atmosphere should be a continually and gradually expanding conduit.

The "turbulent-head" tests are of less general interest. It was shown that with such a special head decrease in flow resistance is more readily accomplished for the outlet direction than for inlet.

The special valves tested for inlet flow behaved similarly to a kind of resonator described by J. Hartmann.[9] He placed cup-like obstructions in the path of an air jet discharged from a rounded orifice into the atmosphere. His reservoir pressure is above critical. He states that this device will convert as much as 10 to 20 per cent of the energy of adiabatic compression into sound-wave energy. He thus produced as much as 74 watts of sound-wave power when using an orifice 1 mm. (0.040 in.) in diameter. He was able to produce waves in both audible and inaudible ranges. In the present case velocities over that of sound can be accounted for only by expanding air path. Assuming otherwise that phenomena are similar, this accounts for the whistling and for the low-frequency oscillations and instabilities. The conversion of so much of the energy to sound incidentally means considerable increase of apparent flow resistance.

[9] J. Hartmann, "On the Production of Acoustic Waves by an Air Jet of a Velocity Exceeding That of Sound," *Phil. Mag.*, London, no. 72, April, 1931.

Conclusions

1 Inlet valves of conventional types perform in engine assembly approximately as they do in model tests. The results of Tanaka and those of the present experiments are suitable for design purposes.

2 Exhaust-valve tests in models are misleading unless the possible extent of diffuser action is known and understood. Such action should be eliminated or should be made to correspond to actual engine conditions. Model tests of exhaust valves by Tanaka and by the authors have given results unsuitable for design purposes. The present results with exhaust valves mounted in the cylinder head are to be preferred as design data.

3 Improvement in valves may be effected by designing the flow path as a diffuser. This may be done locally at the valve head and seat, or in the passage above the valve, or in both ways. The former method is effective both for inlet and exhaust; the latter for exhaust only. Preferably both methods should be combined in the exhaust valve and passage design.

In closing, the authors wish to acknowledge their indebtedness to Dr. O. Tietjens for helpful comments and suggestions, and to Messrs. J. B. Ames and R. L. Taylor for valuable assistance in the experiments and in the labor of calculation.

Development of the Double-Acting Engine

By LOUIS R. FORD,[1] NEW YORK, N. Y.

In less than a decade there has been development of the Diesel double-acting engine into a reliable prime mover. Double-acting engines for large power-plant work are attracting attention. A committee studying types of equipment for the extension of the Copenhagen electric-power station has recommended acceptance of a Burmeister & Wain double-acting, two-cycle engine of 18,500 b.hp., with continuous overload capacity of 22,500 b.hp. At present the two-cycle type has forged ahead of the four-cycle design. The steps in the development of the double-acting engine are reviewed by the author.

THE development of the Diesel engine as a type has been so swift that at least an annual survey is required if one wishes to keep fairly conversant with current design practice. The particular phase of this development that has moved most swiftly in the last few years has been the transformation of the double-acting engine from a laboratory mechanism into a reliable prime mover, available commercially in a number of different makes. Although attempts were made 18 years ago to adapt the Diesel engine to double-acting operation, little progress resulted from these attempts, and the double-acting Diesel engine of today may be said to represent the result of serious and active development work of less than a decade.

Several factors acted to retard earlier development, one of the most important ones being the general disruption of engineering and industrial plans by the World War. But even if this interruption of orderly progress had not occurred, it is doubtful that this early work would have put us any further ahead with double-acting engine construction than we are today. In the first place the practical realization of the Diesel principle, as represented by the single-acting engine, had not proceeded far enough 18 years ago for us to be ready for the double-acting type. Also, the necessary stimulus was lacking; there was not enough demand for engine power high enough to be beyond the limits of the single-acting type

At that time the field of the Diesel engine was considered to be a definitely limited one, but as more was learned about injection, combustion, cooling, and other problems involved in Diesel-engine construction and operation, and better materials and mechanical processes became available, the boundaries of the field constantly receded. In the marine field the very successful application of Diesel-engine drive to larger and larger vessels brought the single-acting engine up to what appears to be limiting cylinder diameter, and the demand for higher power, coupled with the space limitations inherent in marine construction, supplied the stimulus required for active development of the double-acting engine.

It is in the marine field, then, that we must look to get a picture of this development which has now reached the point where double-acting engines for large power-plant work are attracting wide attention. As an indication of the trend in this direction, it is interesting to note that at the time this is written a committee appointed to study the types of equipment offered for the extension of the electric-power station at Copenhagen, Denmark, has recommended acceptance of a Burmeister & Wain double-acting, two-cycle engine of 18,500 b.hp., with continuous overload capacity of 22,500 b.hp.

The beginning of the period of active development referred to was marked by the start at about the same time of design studies for both the two-cycle and four-cycle types, but the latter was put far in the lead commercially by the great prestige of the famous firm by which it was sponsored, as well as by that firm's superior facilities for promoting it. The four-cycle type was heavily handicapped, however, by the mechanical complication inherent in the four-cycle principle of operation, a complication far more pronounced when we try to use both ends of the cylinder than when combustion is confined to the upper end. The elimination of much of this mechanical complication, made possible by the use of the two-cycle principle, is responsible for a steady trend toward the two-cycle type. At the present time it has forged ahead of the four-cycle in number of engines under construction. An indication of this trend is found in the fact that during the last year the firm that has been almost fanatical in its adherence to the four-cycle principle has bowed to the inevitable and placed a two-cycle design on the market. Discounting the risk incurred by all would-be prophets of being confounded by unforeseen conditions that may develop in the future, it is safe to predict that the four-cycle, double-acting engine of large size will pass out of the picture before very long.

Although it is of course expected that continued improvement of the double-acting engine may bring about great changes in construction, the first stage of its development, from an experiment to a practicable machine of proved performance, may be considered as completed, and it is of interest to review some of the steps in that development. Without considering the non-engineering factors that have a great influence on the commercial development of any machine, it is of interest to the engineer to view the mechanical development by observing the structural elements that prove so troublesome in operation as to require corrective redesign. The author is in a position to make such observations by reason of having had, throughout this development period, to make maintenance repairs on a number of large double-acting engines of different makes. It should be remarked at this point that the author does not pretend to have a knowledge of the inside history of the design work of any engine builder. The remarks that follow are based on observation of various en-

[1] Consulting Engineer, Physics Building, Columbia University. Mem. A.S.M.E. Mr. Ford, upon completing his apprenticeship in the machinist trade, entered the United States Navy as a machinist, second class, passed through the various enlisted grades to warrant rank, and in 1912 passed his examination for ensign. He was commissioned with the Naval Academy class of that year, and after a year's service at sea was assigned to take a post-graduate course in engineering at the Naval Academy and Columbia University, receiving his M.A. from the latter in 1915. He served throughout the World War in the submarine force, and in 1919, after 17 years' service in the Navy, resigned as Lieutenant Commander to become associated with the Worthington Pump & Machinery Corporation as chief operating engineer. In 1922 he resigned from this position to take charge of the Diesel engineering activities of the Morse Dry Dock & Repair Company, now a unit of the United Drydocks, Inc., and to establish a general consulting practice.

Presented at the National Oil and Gas Power Meeting, University of Wisconsin, Madison, Wis., June 23–26, 1931, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

gines in service, repairs and changes made on these engines, and some slight contact with the engineering analyses of problems that have arisen in operation.

In the preliminary stages of double-acting engine design it was assumed that the chief difficulties would be to obtain good combustion in the lower end of the cylinder and prevent leakage around a piston rod operating in an atmosphere of flaming gas at high pressure. This despite the fact that for many years double-acting gas engines had operated without any particular difficulties of this sort. As a matter of fact, these features prove to be the source of practically no trouble, but other troubles developed at points where they were least expected. In the Burmeister & Wain engine—the first design to pass successfully the tests of commercial use—the anticipated piston-rod trouble was guarded against by removing the rod from the flaming gas. This was accomplished by enclosing the rod in a tubular sleeve, extending from the under side of the piston to the crosshead, the internal diameter of the sleeve being large enough to provide an

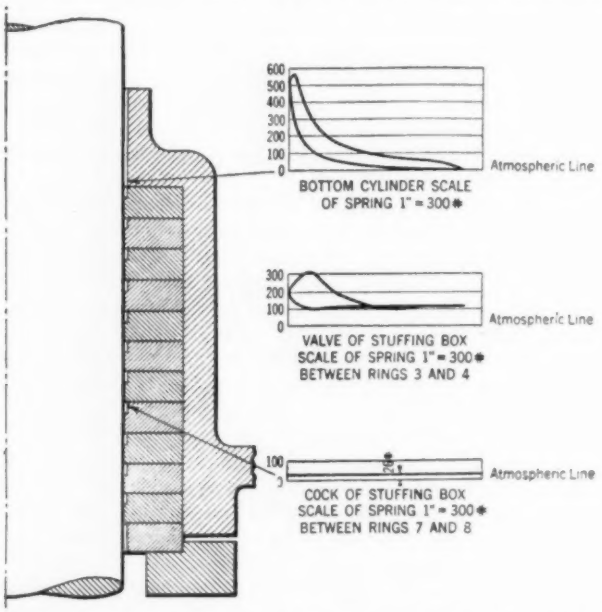

FIG. 1 PISTON-ROD PACKING, WORTHINGTON ENGINE, SHOWING PRESSURE AT DIFFERENT POINTS

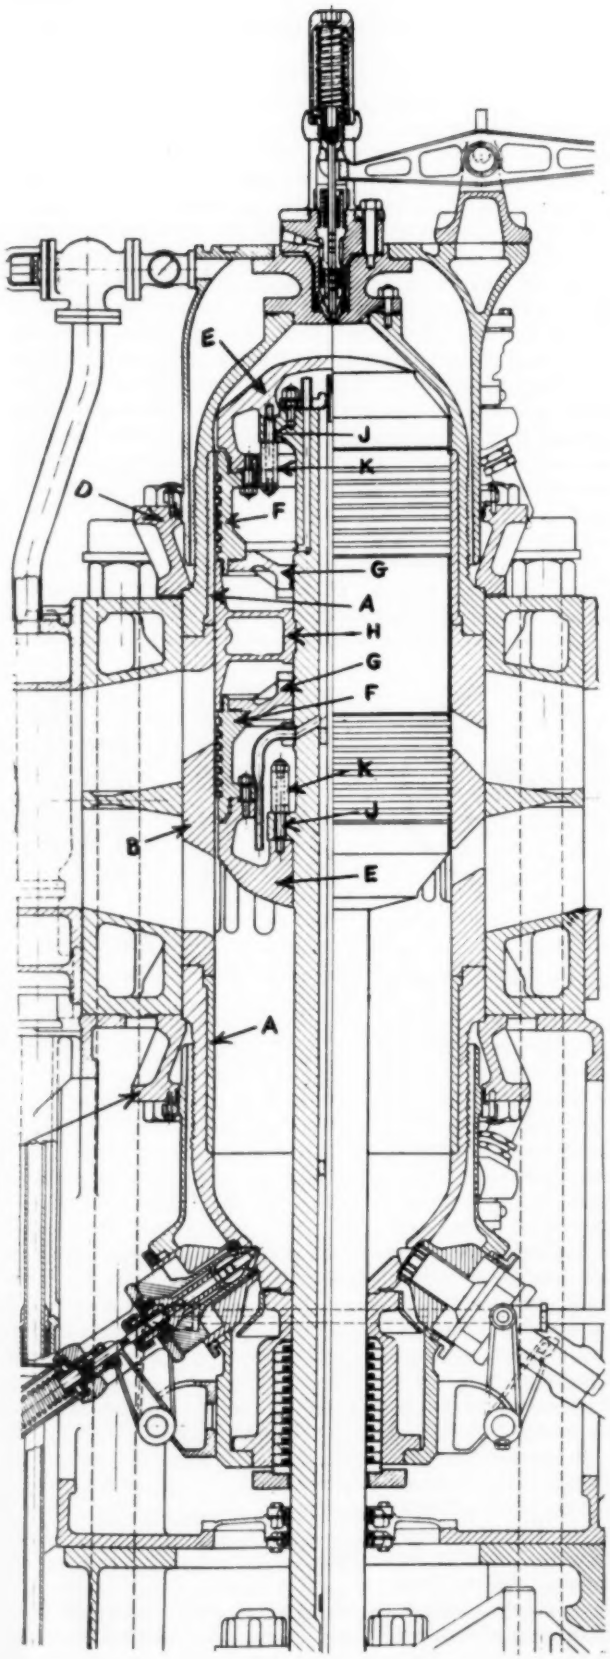

annular space between rod and sleeve. This annular space was utilized as a passage for the piston-cooling oil. Where the piston-rod sleeve passed through the cylinder head a stuffing box was provided, with cast-iron snap rings, just like ordinary piston rings, except that the spring was inward instead of outward. This produced a condition almost similar to that found within the cylinders of all engines, the stuffing box with its packing rings representing the ordinary piston and piston rings, and the surface of the piston-rod sleeve representing the cylinder liner. This device proved highly successful in service and has been incorporated in this firm's newest two-cycle engine.

That this arrangement, although successful, was not needed is indicated by the success of other builders in using plain cast-iron rings in the stuffing box, bearing directly on the piston rod, without any protecting sleeve. As a builder of successful double-acting gas engines in which such packing was used, it was logical that Worthington should use the plain-ring stuffing box in its double-acting Diesel engine. When the first Worthington engine was tested, indicator diagrams were taken to determine the pressure at different points in the stuffing box. Fig. 1, taken from the Worthington catalog, shows that the pressure dropped from 570 lb. at the first ring to 28 lb. at the eighth. The absence of any leakage from the gland indicates that a further drop to zero pressure occurs somewhere before the last ring. These rings are of a good grade of cast iron, made in sections, and held against the rod by simple garter springs. Almost exactly the same type of packing is used in the Deutsche-Werke engine. The author had occasion to remove the packing from two Worthington engines and two Deutsche-Werke engines after one year's service and six months' service, respectively, and all of the rings and piston rods were found to be in excellent condition.

This same principle has been followed by practically all engine builders except Burmeister & Wain, but in some cases the mechanical arrangement is rather elaborate. An example of this is the packing used in the A.E.G. engine, which consists of a packing sleeve, or ring carrier, built up by stacking on top of one another a series of solid rings shaped like the follower, or bull ring, of the steam-engine piston, and placing packing rings in the slots formed between these solid rings. There are two packing rings in each slot, and these are pressed against the rod by a spring ring behind each pair. The whole assembly, consisting of packing rings, spring rings, and solid rings, is held together by bolts and slipped into a stuffing box in the cylinder head. In general it may be said that experience with the engines in service has shown that the piston-rod packing may be very simple in design if the shopwork is sufficiently good. The bearing surfaces must be carefully finished, and the fitting must be very accurate.

The other anticipated trouble—obtaining good combustion in the lower end of the cylinder—did not develop to the extent expected. All of the mechanism related to fuel injection and combustion in the upper end of the cylinder presents no problems not common to both single-acting and double-acting engines. Development of the mechanism of injection and combustion is, then, in so far as it relates solely to the double-acting engine, confined to the lower end of the cylinder. In both the four-cycle and two-cycle types the first problem is to obtain good distribution of fuel in the air in a combustion chamber obstructed by a large piston rod. Since this rod, with its stuffing box, uses up a large amount of the space available in the cylinder head, a second problem is introduced—that of finding a place for the fuel valves without unduly complicating the head casting and without too much interference with circulation of cooling water. In the four-cycle type a further complication results from the necessity for inlet and exhaust valves.

A very practical solution of these problems was worked out by Burmeister & Wain in their four-cycle design, in which the combustion chamber formed by the clearance space in cylinders of orthodox design was replaced by a combustion chamber cast on one side of the lower cylinder head. Practically all of the combustion space volume is concentrated in this side chamber, which is connected by a port to the very small clearance space under the piston. This arrangement puts the combustion air where it can be easily reached by the injected fuel and provides a convenient place for mounting the fuel, exhaust, and inlet valves. In the Werkespoor design the same idea was adopted, but the combustion chamber was made so large that the compression volume is too great for full Diesel compression. As a result the engine must be started single-acting and operated as such until the lower end is warmed up enough to raise the compression temperature to the fuel-ignition point. In the Burmeister & Wain design the possible ill effect of the burning gases sweeping out of the combustion chamber on to the piston rod is prevented by the previously mentioned sleeve which surrounds the rod. The Werkespoor has no such sleeve, but the rod is protected by the expedient of casting a boss on the bottom of the piston, around the bore for the piston rod, and providing a corresponding recess

in the bottom head to receive this boss when the piston is at the end of its stroke. The length of this boss is such that it does not leave the recess until about 8 per cent of the stroke has been completed and combustion is well over. So far as the author knows, the only four-cycle design that places the inlet and exhaust valves directly in the head is that of McIntosh & Seymour. Experience in dismantling and assembling both Burmeister & Wain and McIntosh & Seymour cylinders indicates that the side-combustion-chamber arrangement gives better access for such work.

The builders of two-cycle, double-acting engines, not having the inlet and exhaust valves to contend with, have not used the separate combustion-chamber idea, preferring to inject the fuel directly into the clearance space under the piston. Since this space, because of the presence of the piston rod, has the shape of an annulus, a single valve will not give the desired dispersion of the fuel mist throughout the air, and it is general practice to use two or more injection valves.

As will be seen from Fig. 2, the Worthington design uses two valves, set at an angle to the vertical center line through the cyl-

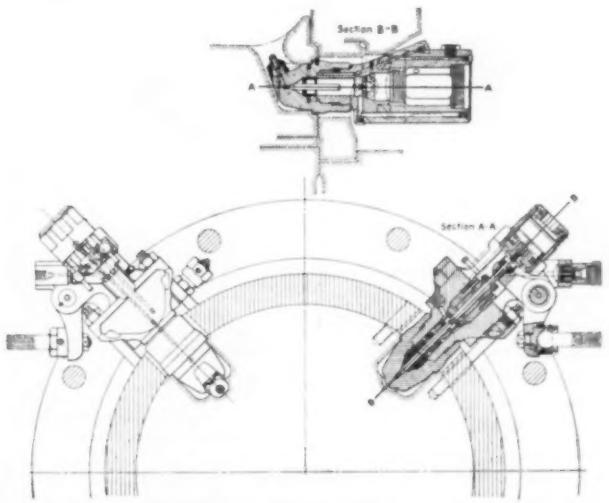

FIG. 3 ARRANGEMENT OF FUEL VALVES ON M.A.N. ENGINE

inder, an arrangement to which the domed shape of the cylinder end is particularly well adapted.

The Deutsche-Werke design uses two valves, but they are not placed in the cylinder head. An intermediate ring, called a valve plate by the builders, is inserted between the cylinder and cylinder head, and the fuel valves are placed horizontally in this ring, diametrically opposite each other and positioned so that the center of the fuel spray is approximately tangential to the piston rod.

The M.A.N. design does not use the tangential spray idea. To obtain wide distribution of the fuel and avoid striking the piston rod with the spray, four fuel valves are used, spaced evenly around the cylinder, as shown in Fig. 3. It will be noted from the figure that the valve bodies are positioned horizontally, but the tips are turned upward so that the sprays enter the cylinder almost vertically. It is obvious that the use of four valves complicates the operating gear. An effect of the vertical sprays that has been noted in operation is the burning of cavities in the bottom face of the piston. It is necessary at times to fill up these cavities by welding in new metal.

FIG. 2 WORTHINGTON DOUBLE-ACTING ENGINE, SHOWING ARRANGEMENT OF FUEL VALVES AND DETAILS OF PISTON

(*A*, cast-iron cylinder liners; *B*, port section liner; *C*, lower clamp rings; *D*, upper clamp ring; *E*, forged-steel piston crowns; *F*, cast-iron ring carrier; *G*, split plate closing piston head; *H*, intermediate skirt; *J*, piston crown studs; *K*, distance pieces.)

The success achieved years ago in the use of mechanical, or airless, injection of fuel in small engines, and the attractive possibilities in the way of simplification offered by this method of injection, led to its intensive development. This resulted in a steady increase in the size of cylinder in which it is possible to use mechanical injection. When the success of the double-acting engine became assured and the use of mechanical injection on large single-acting engines had demonstrated the practicability of that system, it was but logical that the combination of the double-acting, two-cycle principle with mechanical injection of fuel should appeal to designers as the most desirable means for obtaining greater simplicity.

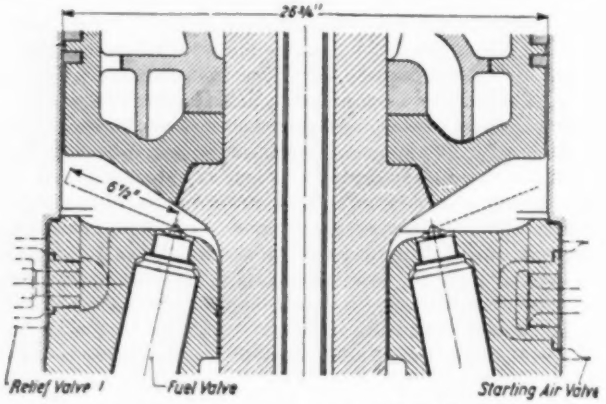

FIG. 4 ORIGINAL ARRANGEMENT OF A.E.G. FUEL VALVES

FIG. 5 LATER ARRANGEMENT OF A.E.G. FUEL VALVES

From the great amount of experimental work done with mechanical-injection systems we have definitely established two important features of the mechanically induced spray. The form of spray that breaks up the fuel fine enough for effective mixture with the air will not penetrate the dense air in the combustion chamber more than 7 or 8 in., and the spray that will penetrate for longer distances does not give the necessary pulverization. As a result of this, in all double-acting engines in which mechanical injection is standard equipment each builder uses the same method to obtain proper distribution of the fuel in the lower combustion chamber—a multiplicity of sprays of limited penetrating power.

A feature of the spray induced by forcing the fuel at high pressure through an orifice is that various shapes and lengths of sprays can be obtained from a multiple-jet valve by simply varying the shapes of the orifices. Examination of three makes of double-acting engines that use mechanical injection shows some different ways in which this principle is applied.

As originally designed, the A.E.G. engine used five spray valves in the lower head, arranged around the piston-rod stuffing box as indicated in Fig. 4, the jets being projected outward toward the cylinder wall. This arrangement was later changed to that shown in Fig. 5, in which only two valves are used, each discharging two sprays, the outer spray being in each case shorter than the inner, because of the difference in the distances through which the fuel must be projected. Theoretically this second arrangement should be superior to the first because of the influence of the sprays causing the air to whirl around the piston rod and promote mixture of air and fuel.

In the M.A.N. engine there is a spray-valve arrangement quite similar to that of the original A.E.G. design, except that only two valves are used, and wide dispersion of the fuel charge is obtained by using six orifices, as shown in Fig. 6. Here, also, the sprays are of different lengths, according to the length of path to be traversed, but the whirling effect on the air is absent.

In the Richardson-Westgarth engine is found an interesting example of the use of different lengths of sprays, as shown in Fig. 7. Two valves, diametrically opposite each other, are placed vertically in the cylinder head, near the outer periphery of the combustion space. As shown in the sketch, each valve discharges five sprays, four of them horizontal and one vertical. Because of the short distance between the valve nozzles and the face of the piston, the vertical sprays are widespreading, with little penetrating power. It is pertinent to remark at this point that the author does not claim that the several sketches accurately portray the spraying actions obtained; they simply show the effects sought by the designers in each case.

A feature of Diesel-engine operation that is easily taken care of in single-acting designs, but which has largely controlled the general arrangement of the double-acting cylinder structure, is the longitudinal expansion of liner and jacket. This presents

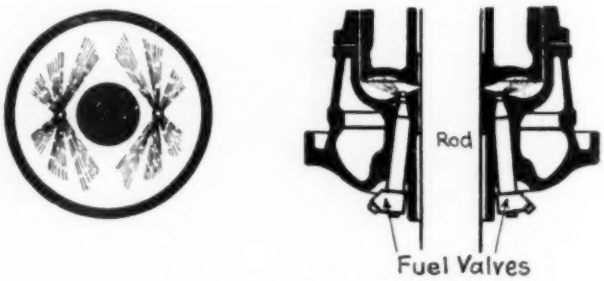

FIG. 6 ARRANGEMENT OF M.A.N. FUEL VALVES

no problem in the case of a cylinder open at one end, but when this cylinder has to be closed and used as a combustion and pressure vessel at both ends, it becomes an important factor. It is this factor that is responsible for the generally used method of construction whereby the cylinder consists essentially of two single-acting cylinders placed end to end.

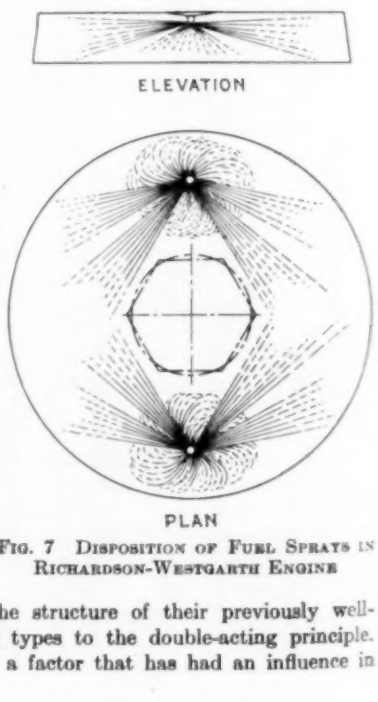

FIG. 7 DISPOSITION OF FUEL SPRAYS IN RICHARDSON-WESTGARTH ENGINE

In considering the cylinders and frames, it may be noted that in the cases of the two successful four-cycle designs the builders have simply adapted the structure of their previously well-established single-acting types to the double-acting principle. In the two-cycle design a factor that has had an influence in

producing almost a standard type of structure is the necessity for establishing, at the middle of the cylinder, connections between the ports and the exhaust and scavenging passages. This suggested the idea of a main fixed structure, of beam type, containing the exhaust and scavenging passages and supported by the frame, with the upper and lower elements of the cylinder attached to its top and bottom, respectively. This arrangement, first used in the Worthington engine, is now used in the Earle, Krupp, and Richardson-Westgarth. A notable departure from this standard type of construction is found in the M.A.N. two-cycle design. Originally the main fixed structure of this engine consisted of the frames, supporting an entablature on which were mounted secondary frames, which supported on their tops an upper entablature. The cylinder jacket and lower half of the liner rested on top of the lower entablature, while the upper half of the liner hung from the under side of the upper entablature. This gave great freedom for expansion, but made the lower head inaccessible. For this reason the design was later changed so that the entire cylinder hangs from the upper entablature, leaving room below it to remove the lower head and lower section of the liner. It may be noted in this connection that in order to make removal of the lower liner section possible it has been shortened and all of the ports placed in the upper liner section.

This matter of liner removal did not receive the attention it deserved until liner breakages in service made it evident that such removal must be made easier if overhaul expense was to be kept within bounds. An example of the development of this feature is found in the Worthington engine, first used in marine service. As originally designed, removal of the top cylinder section and its liner was quite easy, but to get the bottom section out it was necessary to remove the entire cylinder block, weighing several tons, and turn it upside down while suspended in the air. This required expert riggers and equipment not ordinarily available on shipboard. This design was changed so that the liner is now made in three sections. The upper cylinder section can be lifted off, the middle liner section taken out, and the lower cylinder section pulled up through the housing, all with the ordinary ship's gear, without distributing the more massive elements in the engine structure. The same feature has been incorporated in the designs of the Deutsche-Werke, Earl, Krupp, and Richardson-Westgarth. In general it may be said that great progress has been made in the direction of simplification of the cylinder unit to permit easy assembly and disassembly.

This particular phase of development has been accelerated by the frequent breakage of liners in the earlier engines, a condition that gave the liner an undeserved reputation as a troublesome element. Experience, however, developed the fact that liner breakage is in practically every case due to piston trouble and not to any fault in the liner itself. There is no difficulty originating within the liner itself that is not common to both the single-acting and double-acting types. The chief problem with both is the prevention of rapid wear. This wear usually proceeds at a maximum rate during the first 1000 hours of operation, due to initial wearing-in. This wearing-in that has heretofore been considered a necessary part of the "breaking in" of an engine can be eliminated if the engine builders will adopt the same standards for cylinder finish as used by the automobile manufacturers. Already some builders have adopted the grinding process for finishing small cylinder liners. Further progress will be made when it is recognized that a final finish by honing will do a lot toward reducing the rate of liner wear. Experience with numerous double-acting engines in service indicates a wide variation in the rate of wear of liners, but in any case where wear occurs at an unusually rapid rate its cause can usually be traced to some abnormal condition of operation. For liners as at present produced it may be assumed that 0.005 in. wear per 1000 hours of operation is a liberal allowance. Any rate of wear greater than this is excessive.

Much of the operating trouble with double-acting engines has been due to the pistons, although in some cases it required repeated casualties to reveal the identity of the piston as the source of the trouble. In the beginning of double-acting engine design the structural features required to make a good piston were fairly well understood. The educating effect of experience is shown by a better understanding of the most effective mechanical form these features should take, rather than by any change in the features themselves. Fundamentally the piston is a highly stressed

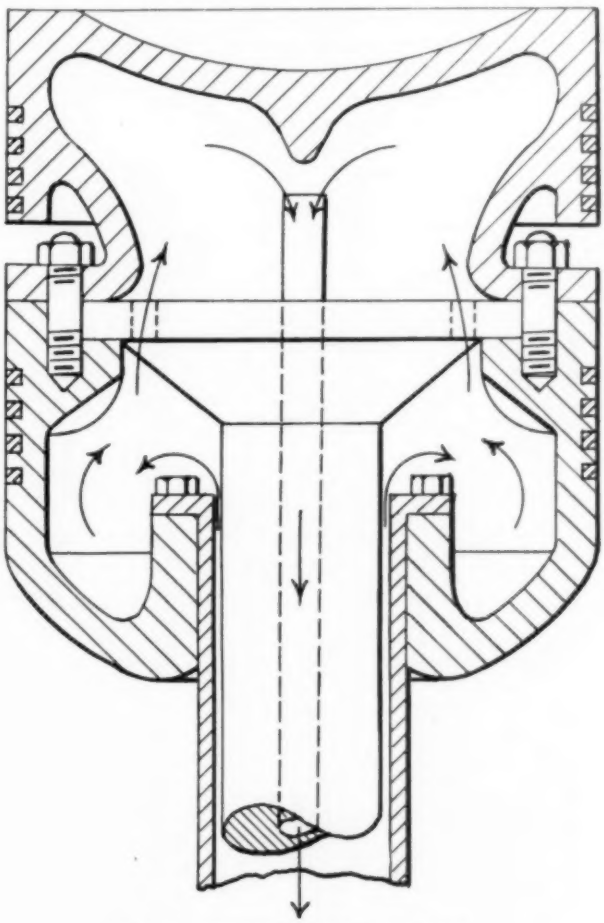

FIG. 8 BURMEISTER & WAIN PISTON

member that must be rigidly connected to the piston rod, yet free to distort under the influence of high heat without excessive stress. Provision must be made for intensive cooling with water or oil, and it is the devising of a practical method of passing this cooling fluid into, through, and out of the piston in such a way as to provide adequate cooling without leakage into the cylinder that constitutes the chief problem of piston design. The only available path through which the cooling fluid can reach the piston is through the piston rod, and the most practicable way of making two flow paths, one for inlet and one for outlet, is to insert an axial tube in the piston-rod bore, utilizing this central tube for one path and the annular space around the tube for the other. A variation of this arrangement is possible with the Burmeister & Wain engine with a protective sleeve around the rod. The space between this sleeve and the rod is used for the incoming oil, and the outflowing oil is passed through the bore of the rod.

In every double-acting engine the piston is essentially two single-acting pistons placed end to end and fastened together, but there are some distinctive differences in the details of construction of the different makes.

The simplest of all double-acting pistons is the Burmeister & Wain, as may be seen in Fig. 8. The two sections are bolted to a singly flange on the rod, a single set of studs serving to secure both sections. The path of the cooling fluid is shown by the arrows in the sketch. It is worthy of note that it has been found necessary to make very little change in this design since the first engine was produced. It is also interesting to note that this same design was adapted to the two-cycle engine recently put out by this firm by simply lengthening the side walls of the upper section, thus giving the extra length needed for two-cycle operation without the addition of the intermediate skirt found on practically all other designs.

What appears to be the most elaborate piston design is found in the A.E.G. engine. Referring to Fig. 9, it may be seen that there are five separate parts. The upper and lower heads, *U* and *P*, are separated by a trunk, in two parts, *D* and *O*, these two sections being bolted together by means of flanges. The complete assembly, consisting of upper and lower heads and the two trunk sections, is held on the piston rod by the large nut *M*, which presses the lower trunk section down on shoulder *B* on the rod. The space between upper and lower piston heads is closed by the split cast-iron skirt *A*. To provide intensive cooling of the piston heads the cooling water is guided through channels formed by extending the center column sections into the piston heads and casting ribs on these extensions. The path thus formed may be traced by means of the arrows in the sketch. It may be noticed that this design eliminates all sliding joints in the piston assembly. An interesting detail not found in other designs is a provision for changing the piston length, for adjusting compression, by means of liner *Z*, inserted between the two halves of the inner column. The piston heads are of forged steel and the central column of cast steel. Since in the original design of this engine the liners were of forged manganese steel, rubbing contact between piston heads and liner was avoided by making the cast-iron skirt larger in diameter than the heads. Trouble was experienced due to heating and distortion of the skirts, this distortion causing the skirt bolts to stretch or break. To correct this the skirt was made in two parts—an upper part, about 14 in. long, being made in the form of a solid ring, and the lower part in the original split form. The split section was given 2.8 mm. greater clearance than the solid ring to insure all the bearing being on the latter. After further experience with the first engine the manganese-steel liners were abandoned for cast-iron liners.

The changes that have been made in the Worthington piston as the result of operating experience may be seen in Figs. 10 and 12, which show, respectively, the original design and the modified

design found in later engines. The original make-up, consisting of forged-steel piston heads with cast-iron ring carriers and a cast-iron skirt for closing the space between upper and lower piston sections, has not been changed. The principal change is the removal of the packing gland that closed the joint between the flanged lower end of each ring carrier and the piston-rod flange. To effect this the modified design provides for closing the end of each ring carrier with a flat plate, made in halves and bolted rigidly to the ring carrier. The inner edge bears against the rod and is made tight by simple rubber rings in grooves. This does away with the troublesome gland and removes the packed joint from a region of high heat to a much cooler one. This change permitted the use of short studs, shown at *J* in Fig. 2, in place of the long studs used in the original design for fastening the piston heads to the rod. This later change developed another source of trouble. Distortion of the steel piston head caused the flange held by these studs to cock on its seat and break the short studs. In one of these pistons opened by the author it was found that the broken studs, with their nuts, had rattled around in the piston until holes were worn through plate *G*. To remedy this, the studs were lengthened, and a sleeve *K* was placed under each nut.

In the Deutsche-Werke piston, shown in Fig. 11, there are the conventional elements, two piston heads, the lower of cast steel and the upper of cast iron, with a split skirt of cast iron to close the space between them, but in place of the separate ring carriers of the Worthington piston the piston heads have extended skirts carrying the rings. The upper piston head, instead of being attached directly to the rod, is bolted to a cast-steel distance piece of approximately cone shape, which is secured at its lower end to the flange on top of the piston rod by means of studs, which serve also to fasten the lower piston head to the same flange. A troublesome feature of this piston is the stuffing box *J*, packed with rubber packing and closed by a gland held down by studs and nuts. The author has had occasion to open up 24 of these pistons, and in nearly every case this stuffing box was leaking. In several the rubber packing was cooked to a pasty mass. Repeated breakage of the gland studs also has been found. This emphasizes the fact that a packed gland on the outer wall is a dangerous element in a piston. Another troublesome element in this piston is the split skirt which closes the space between the upper and lower piston heads. Several of these skirts have seized in the cylinders and were distorted enough to break the bolts holding the two halves together. That there is also some distortion of the upper piston heads is indicated by the fact that many of the nuts on studs *L* have become loose in service. It is understood that changes in this piston design have been made, but the author is not familiar with the new design.

In the M.A.N. piston, shown in Fig. 12, there are found the usual upper and lower piston heads, with rings in the skirts and an intermediate skirt to close the space between heads. In addition there is a solid wearing ring *F* attached to the upper piston head. As originally designed, removal of this ring involved dismantling the upper head. To permit easier removal of the ring, some of the Shipping Board pistons were modified by making this ring of two halves, bolted together. The correctness of this change is doubtful in view of the trouble experienced by A.E.G. and Deutsche-Werke with split skirts used as wearing rings. A feature of the M.A.N. piston is the use of bent pipes for circulating the cooling water, as shown in Fig. 12.

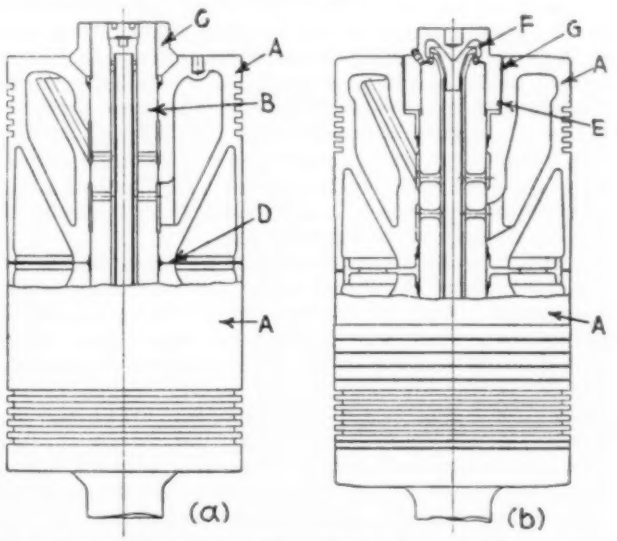

FIG. 13 ORIGINAL (*a*) AND MODIFIED (*b*) DESIGNS OF RICHARDSON-WESTGARTH PISTON

(*A*, upper and lower piston sections; *B*, piston rod; *C*, large nut with cone seat; *D*, seat on lower piston section to receive upper section; *E*, deep recess for nut in modified design; *F*, water passages in nut; *G*, undercut notch for attaching lifting gear.)

The Richardson-Westgarth piston, in its original and in its modified forms, is shown in Fig. 13. It will be noticed that although two similar halves are used for top and bottom there is no intermediate skirt, the skirts of the two piston heads being extended downward to meet at the center, with enough clearance between edges to permit expansion. Another feature of this piston is that the piston rod extends right through both sections and a large nut on the upper end holds the assembly together. The lower piston head rests on a shoulder on the rod, the central boss on the upper head rests on the upper end of the lower head, and the nut presses the whole assembly together. This makes a very simple piston, but it has some glaring defects; the whole assembly is rigidly restrained, with no provision for expansion, the large nut is exposed to the heat of combustion, and the cone-shaped seat of the nut tends to split the top head.

In the modified design these faults were corrected as follows: The seat for the nut was made square and deeply recessed. The seat for the shoulder in the bottom head was similarly recessed, thus leaving the two heads free to expand axially and diametrically. The recessing of the upper head brings the nut below the top of the piston, with the exception of enough projection to permit attaching a wrench. To prevent burning of the nut, water channels are cut in it, and the cooling water leaving the piston flows through the nut to reach the outlet tube in the rod. In addition, the outer surface of the nut is calorized to prevent oxidation in the flame of combustion. A small detail of construction that has given trouble in nearly all double-acting engines is the lifting arrangement. In practically every case where tapped holes in the piston crown were provided for attaching lifting bolts, cracking of the pistons has occurred, the cracks starting at the lifting-bolt holes. Worthington, A.E.G., Richardson-Westgarth and Deutsche-Werke all have eliminated such holes from their latest pistons.

In general it may be said that the main structural features of double-acting pistons have been fairly well standardized in principle, but there is considerable variation in the manner in which these principles find mechanical expression.

Probably the most trouble experienced with double-acting engines has come from a part from which the least was expected, the piston rod. The only anticipated trouble was rapid wear of the rod by its packing. This led the Worthington Company to develop plating equipment and technique whereby their rods could be chromium plated. Their methods proved very successful, but experience with unplated rods in service indicates that this treatment is an unnecessary expense. Measurement by the author of a number of unplated rods after varying lengths of service shows that if the packing is accurately made and carefully fitted very little wear need be expected. The length of service to be expected before such a rod becomes unfit for further use because of wear is as yet undetermined.

Shortly after the first double-acting engines were placed in service, breakages of piston rods began to occur. These were at first ascribed to faulty material or defects in design of the particular engines in which they occurred, but when almost exactly similar breaks occurred in Burmeister & Wain, Worthington, M.A.N., Deutsche-Werke, and other engines it became evident that neither of these causes was the true one. The nature and location of some of these breaks indicated that the generally used method of making cooling-water connections to the rod was responsible for them. Since, as previously stated, the piston rod offers the only means of getting cooling fluid into and out of the piston, and the crosshead offers the most convenient point for making the connection between the moving and the stationary members of the cooling system, nearly all builders used some sort of bracket on the crosshead with connections to drilled holes through the sides of the piston rod. The method of making these connections was usually to mill a flat on each side of the rod in the way of the drilled holes and bolt the pipe flanges to these flats with studs tapped into the rod. The combination of water passages, stud holes, and facings for flanges decidedly weakened the rod at this point, with the result that several builders had rods break in this weakened section. The sketch in Fig. 14 made from one such rod is typical of what occurred. This sort of thing, occurring in several different makes of engines, led to the abandonment of this method of connecting the cooling system to the rod. It is general practice now to make such connection by bolting a small divided chamber to the bottom end of the rod, under

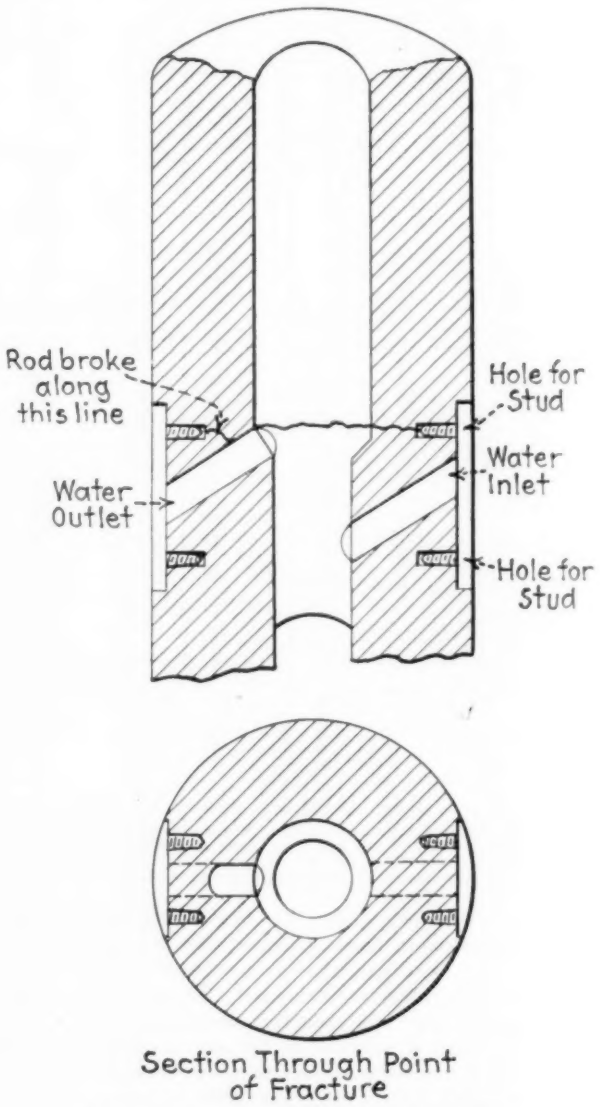

FIG. 14 TYPICAL FORM OF PISTON-ROD BREAK

the crosshead, with one part of the chamber connecting with the axial pipe in the bore of the rod and the other to the annular space surrounding the pipe. The inlet pipe is connected to one and the outlet pipe to the other. This eliminates any weakening of the rod by holes or flats.

Unfortunately this did not stop the breakage of piston rods, although it did reduce the number of such breakages. The breaks that occurred after this were confined to no particular point on the rod. One rod removed by the author broke off just

inside the bore in the piston almost as cleanly as though it had been cut in two. Others broke near the crosshead. The cause for such breaks is yet to be definitely determined, but a clue that is being followed with some promise of results is the possible effect of roughening the surface on the inside of the bore of the rod. One manufacturer who has made extended tests tried an experiment that points to a promising line of study. A rod made of high-grade material that gave uniform bending-test results was operated in the engine until it had made several million alternations and the surface of the bore had been roughened by the action of cooling waters. Samples were then cut from the outer and inner surfaces and given a bending test. The sample from the outer surface bent double without breaking, while the one from the inner surface broke after a very slight bend.

It would appear, then, that the surface of the rod bore should be finished as carefully as the outside surface, which is always polished to make a good rubbing surface for the packing. This is borne out by the experience of the Bethlehem Steel Company some years ago with cast-steel crankshafts. They found that such shafts were safe to use if the bore was polished like a gun barrel. A fine finish in the piston rod bore is of no value, however, unless it is protected against roughening by the corrosive effect of the cooling water. Coating of the surface with zinc or cadmium, or the application of metal by the spraying process, does not give a sufficiently durable coating. Chromium plating is durable, but is very difficult to apply in a long bore of small diameter. The company previously mentioned as having made the bending tests has experimented with rods of stainless steel and also with nitrided rods. It is hoped that the information gained by these experiments will be made public.

Another piston-rod trouble, of a minor nature in itself, but having serious consequences, was experienced by several builders before its nature was discovered. This was the corrosion of the lower ends of the internal pipes in the piston rods. The author knows of cases of two different makes of engines in which such corrosion short-circuited the stream of piston-cooling water and caused repeated piston seizures before the nature of the trouble was discovered. It is general practice now to make these pipes of stainless steel.

Of the many elements that go into the structure of a workable double-acting engine there are few other than those discussed in the foregoing that present any problems not already encountered in the development of the single-acting engine. This has been an important factor in the rapid advancement of the double-acting engine to a position of preeminence in the large-engine field. At the present time there is a very definite trend toward the two-cycle type with mechanical injection of fuel. There is no reason to assume that we have yet reached the limit of power that can be built into a single unit, and the increasing number of power-plant installations being made in Europe leads to the hope that similar applications may be seen in the United States. From the author's viewpoint, that of the repair man, the maintenance of such installations offers no more difficulties than does that of the older single-acting engine.

Discussion

HARTE COOKE.[2] The paper brings out a number of interesting points, one being the difficulty encountered with piston rods of very hard steel.

The wear of one of our steam-engine piston rods may be of interest. This was a 6-in. high-pressure piston rod running in metallic packing on an engine in a cement mill which operated practically continuously, with a shutdown two or three hours per week for maintenance. The steam pressure was 180 lb. superheated, and the engine was carrying approximately 50 per cent more load than its original rating.

Due to the breaking of a connecting-rod bolt, the piston rod was bent. A section from this was micrometered and showed the diameter after twelve years' service to be 5.995 in., the wear being approximately 0.005 in. The surface test gave a Brinell hardness of 124. Analysis showed it to be our usual steam-engine piston-rod material of approximately 0.20 carbon plain-carbon steel.

This definite information raises a question as to the necessity of excessively hard piston rods, and these very hard piston rods for other reasons are not desirable, as illustrated by the experience given in the paper.

In regard to vessels with large powers, it is interesting to note that two of the newest large high-speed vessels, the *Reina del Pacifico* and the *Venus*, use four-cycle, trunk-piston-type engines, supercharged. The fact that they are used in these vessels which require so much power would seem to indicate that in the builders' mind the cost per horsepower must compare favorably with the double-acting two-cycle engines.

However, in fairness to the author, it should be stated that one of the desirable features of these supercharged trunk-piston-type four-cycle engines is the low head room required; that is, they could go under the deck.

Light Metal-Alloy Pistons and Rods in High-Speed Industrial Engines

By BENEDICT J. ISIDIN,[1] CLEVELAND, OHIO

The speed of oil and gasoline internal-combustion engines has been brought into a higher range following the availability of improved materials and the necessity of obtaining increased power output without sacrificing space and weight. This often makes it necessary to reconsider some points of design and to adopt better grades of material to solve the problems of higher heat stresses and increase in dynamic bearing loads. Therefore the piston is sometimes cast of steel in thinner section and the cylinder liner is made thinner and is cast of steel to reduce thermal stresses. Connecting rods are made of special alloy steels and can withstand higher stresses than are allowed in plain carbon steel. As a satisfactory means of reducing the weight, the author discusses the use of aluminum, allowing heavier sections, preserving the rigidity, and removing any thermal difficulties encountered in the piston.

IN THE last decade, internal-combustion engines of small and medium output have gained a firm foothold in many special branches of service where the motive power is required at instant notice with guaranteed reliability and economy. Because of the small space it requires and because of its light weight, the internal-combustion engine has become indispensable in solving many problems of agriculture, irrigation, dredging, cotton ginning, excavating, pumping, refrigerating, etc. Both types of this engine (gasoline and oil) are successfully used, depending upon preference or local conditions.

With the course of time, the availability of improved materials, and the economic necessity of getting increased power output without sacrificing space and weight, the speed of these engines has been brought into a higher range. For example, in the case of a dredge, a six-cylinder, 180-b.hp., $6^1/_2$ by $8^3/_4$, 1000-r.p.m. Diesel engine is used; in another installation of a portable air compressor, a 92-hp., four-cylinder, 6 by 8, 1000-r.p.m. Diesel engine is used to advantage. Both of these engines can be classified as high-speed engines.

In order to preserve durability and economical upkeep in high-speed engines, it often becomes necessary to reconsider some points in design and adopt better grades of material to solve the problems of higher heat stresses and increase in dynamic bearing loads. Thus, to withstand higher stresses and to reduce its weight, the piston is often cast of steel with thinner sections. The cylinder liner is made thinner and cast in steel to reduce thermal stresses. Connecting rods, of special alloy steels, are made lighter and can safely withstand much higher stresses than are allowed in plain carbon steel.

In spite of all these refinements in design and materials, the aforementioned problems are only partly solved, mainly because of the limitations of certain physical properties of the materials themselves. The heavy weight and insufficient heat conductivity of steel and cast iron are the main handicaps of these materials in the construction of connecting rods and pistons for these engines. The special alloy-steel connecting rod can be made very light and sufficiently strong, but always with considerable sacrifice of rigidity of construction, as saving in weight is attained by reduction of sections. Rigidity in connecting rods is vital to the life of the bearings, as many minute deflections of the shank throw the bearings out of proper alignment, resulting in quick wear.

Cast-iron or steel pistons, when cast light and in thin sections, are subject to overheating, with resulting carbon formation on the piston head. Local hot spots in the center of the piston head result from the insufficient heat conductivity of iron, and the heat absorbed by the piston head does not flow rapidly enough to the ring belt through the thin sections of the cast-iron piston head. This induces detonation, and in extreme cases is likely to cause the piston to crack, as considerable stress is set up because of the difference in temperature between the red-hot center and the comparatively cool outer edge of the piston head. High temperatures destroy the oil film and carbonize the oil. This results in sticky rings, upsets the lubrication of wristpin bearings, and shortens the life of the piston generally. With increased thickness in the head sections, all of the aforementioned thermal difficulties will be diminished, but the weight of the piston becomes prohibitive for use in high-speed engines.

When the industry itself was in its infancy, low speed, heavy-duty industrial engines were necessarily of low power output. The inertia loads were of no consideration, and all moving parts were made heavy and substantial. It was easy to keep bearings in good alignment, well-lubricated and cool, which resulted in enviable long life.

The designer of modern high-speed industrial engines must preserve this reliability and long life, which is a very honorable but difficult tradition to fulfil, as inertia loads are becoming the predominant factors in engine design. He will be compelled to find new means to reduce the weight of pistons and connecting rods. The most satisfactory way of reducing the weight of these parts is to change the material and to use aluminum, which will allow the use of heavier sections, preserve the rigidity, and remove any thermal difficulties encountered in the piston. By use of aluminum alloys of proper physical properties, it is possible to fulfil all the requirements and obtain pistons and rods which will operate considerably cooler and result in better performance than is obtained from conventional iron and steel parts.

---

[1] Engineering Department, Aluminum Company of America. Benedict John Isidin was born February 25, 1895, in Saratov City, on the Volga, Russia. He was graduated from high school in 1912, and the same year he passed through the competitive examinations to join the Naval Engineers and Architects College, Kronstadt, from which, after completion of a thesis work entitled "Diesel Engines Versus Turbines in Battleships," he was graduated in 1916, receiving a commission in the Imperial Russian Navy as Engineer-Lieutenant (Junior). After graduation from the Submarine Officers' School, he held the position of Chief Engineer in ocean-going submarines, seeing active service in the World War. After the Russian Revolution, Mr. Isidin came to the United States in 1921. Since 1928 he has been with the Aluminum Company of America.

Presented at the National Oil and Gas Power Meeting, University of Wisconsin, Madison, Wis., June 23–26, 1931, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

In general the physical properties of aluminum alloys with which a designer is concerned are as follows:

Specific gravity, 2.7 to 2.9 (cast iron, 7.2; steel, 7.8).

Heat conductivity, 7.7 B.t.u. per cu. in. per hour per 1 deg. fahr. (cast iron, 2.2 B.t.u. per cu. in. per hour per 1 deg. fahr.).

Modulus of elasticity, E = 10,000,000 lb. per sq. in. (cast iron, E = 15,000,000 lb. per sq. in.; steel, E = 30,000,000 lb. per sq. in.).

Aluminum alloys, cast and heat-treated, recommended as a material for pistons: Yield point, 20,000 to 25,000 lb. per sq. in.; tensile strength, 35,000 to 40,000 lb. per sq. in.

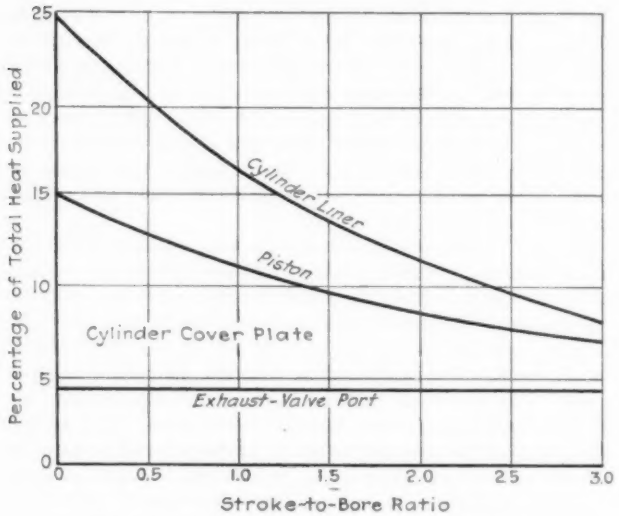

FIG. 1 HEAT FLOW IN A FOUR-STROKE ENGINE

Strong wrought-aluminum alloys recommended for connecting rods: Tensile strength, 55,000 to 63,000 lb. per sq. in.; yield point, 30,000 to 40,000 lb. per sq. in.; Brinell, 90 to 110; endurance limit, 15,000 lb. per sq. in.

Coefficient of thermal expansion, 0.0000123 in. (cast iron, 0.00000556 in. per 1 deg. fahr. per in.).

By using these alloys for pistons and connecting rods, a weight saving of 50 per cent and 40 per cent, respectively, as compared with ferrous materials, becomes possible.

In order to insure satisfactory results when designing parts in aluminum, certain peculiar problems of piston and connecting-rod designs will be considered.

PISTONS

The problems in piston design are mainly those relating to piston-head design and are as follows:

1 Estimation of heat absorbed by piston head
2 Determination of thermal stresses
3 Determination of stresses due to explosion pressure
4 Proper provision for heat transfer from head to rings and piston skirt.

A piston head forms the bottom of the combustion chamber and is the only part of a piston which comes in actual contact with burning gases. These gases being extremely hot, supply, during combustion and exhaust strokes, a certain amount of heat which flows almost entirely (disregarding radiation, which is considered very small) to the cylinder wall through contact areas.

H. F. P. Purday, on the basis of the experiments carried out by Professor Hopkinson and others, evolved diagrams, Figs. 1 and 2, showing heat flow to the piston, cylinder liner, etc. (See "Diesel Engine Design," pp. 170–171.) In these diagrams the percentage of heat passing to the piston liner, etc., is plotted on the basis of the stroke-bore ratio. The total jacket heat is assumed to be 25 per cent of the total heat supplied. When an approximate estimate of heat flow is needed, as is the case when designing engine details such as pistons, liners, etc., these diagrams are very helpful.

When using these diagrams, the quantity of heat flow per square inch of piston head per hour can be estimated as $F = \frac{18{,}000 \times a \times 0.42 \times \text{b.hp.}}{\text{Piston head area, sq. in.}}$, where 18,000 is the calorific value of fuel oil in B.t.u. per lb., a is the heat absorbed by piston in per cent of total heat supplied, 0.42 is the usual fuel consumption in lb. per b.hp. per hour for Diesel engines. The value of this data, as will be shown later, is needed in computing head thickness and thermal stresses.

Heat absorbed by the piston head flows through the head toward the cylinder wall. This condition naturally necessitates an assumption of a temperature drop from the center toward the edge. In the case of a plain disk of even thickness, which condition approximates that of a conventional flat-head piston, the heat flow is governed by formula: $T_C - T_E = \frac{F \times D^2}{16 \times t \times K}$, where $T_C - T_E$ is the temperature difference between the center and the edge of the disk, F is the mean quantity of heat absorbed per square inch per hour, D is the disk diameter in inches, t is the thickness of a disk in inches, K is the heat conductivity in B.t.u. per cubic inch per hour per 1 deg. fahr. This formula indicates that with a given heat flow F B.t.u. per sq. in. per hour, diameter D, and the thickness of the disk t, the temperature difference will be inversely proportional to the heat conductivities of the materials involved. Thus, in the case of aluminum alloy and cast iron, under these conditions, the temperature difference for the aluminum disk will be about one-third the temperature difference of cast iron. Actual temperature measurements by means of thermocouples, made in cases where experience indicates that cracking is not to be anticipated, show that a safe maximum value of $T_C - T_E$ for cast-iron pistons is about 400 deg. fahr. with a temperature in the center of about 800 deg. fahr. If the cast-iron piston is replaced by an aluminum-alloy piston of the same head thickness, the temperature distribution in the aluminum piston head follows essentially the inverse ratio of heat conductivities, as described, or the temperature difference becomes reduced to 130 deg. fahr., and the temperature in the center of the piston head will be in the neighborhood of 500 deg. fahr.

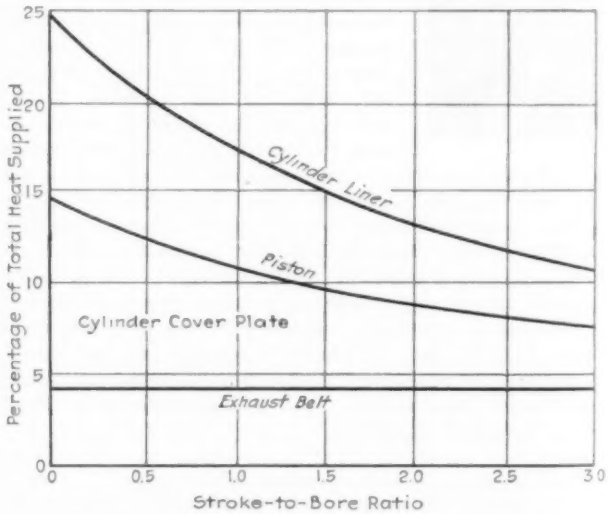

FIG. 2 HEAT FLOW IN A TWO-STROKE ENGINE

Thermal stresses in plain disks can be estimated by the formula $S = \frac{(T_C - T_E) \times E \times \alpha}{2}$, where E is the modulus of elasticity and α is the coefficient of thermal expansion of metals used. The thermal stresses set up in the piston head will be more complicated than in the plain disk, but less dangerous because of the strengthening of the head by the trunk of the piston. Thus, the formula would not represent the actual thermal stresses in a piston head and is used only for comparative purposes.

With the extreme temperature difference of 400 deg. fahr. allowed in the cast-iron piston, the thermal stresses will be about 13,500 to 15,000 lb. per sq. in., depending upon the value of modulus E (12,000,000 to 15,000,000 lb. per sq. in.). These stresses appear to be high for cast iron (ultimate strength, 25,000 lb. per sq. in.) and may serve as a forewarning, showing the thermal limitations of the metal. In the case of the aluminum alloys used in pistons, though the modulus of elasticity and tensile strength are affected by high temperatures, and at 500 deg. fahr. become correspondingly 5,500,000 and 26,000 lb. per sq. in., the thermal stresses in aluminum disks with a temperature difference of 130 deg. fahr. will be only $S = \frac{(T_C - T_E) \times E \times \alpha}{2} = \frac{130 \times 5{,}500{,}000 \times 0.0000123}{2} = 4400$ lb. per sq. in. (yield point of aluminum alloy for pistons at 500 deg. fahr. = 18,000 lb. per sq. in.). This is indicative of a better safety factor and of a wider range of application.

Returning to the formula $T_C - T_E = \frac{F \times D^2}{16 \times t \times k}$, which can be rewritten as $t = \frac{F \times D^2}{16 \times K \times (T_C - T_E)}$, it becomes possible to

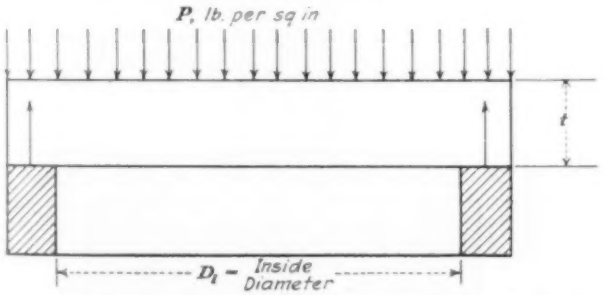

Fig. 3 Flat, Round Disk Under Action of Two Bending Moments in Opposite Directions

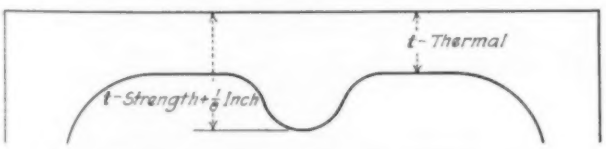

Fig. 4 Reinforcement of Disk by Longitudinal Rib

calculate the head thickness of a piston for any given heat flow F in B.t.u. per sq. in. per hour, diameter D, and for any predetermined safe temperature difference. As was shown, for the lightest cast-iron piston design, which is reasonably safe, the value of $T_C - T_E$ becomes 400, and the piston-head thickness can be expressed as $t_{CI} = 0.000071\,FD^2$. In order to get a temperature difference of 130 deg. fahr. in an aluminum piston, under the same conditions, the head thickness will be $t_{AL} = 0.000063\,FD^2$. This indicates the possibility of a weight saving of 65 per cent as compared with cast iron, but usually the sections are cast heavier in aluminum than in cast iron since the main motive for substituting aluminum for cast iron is to increase the power (this increases F), and also to provide rigidity comparable or better than cast iron. As a result the total weight saving will be about 50 per cent as compared with the cast-iron piston.

In the foregoing discussion, the stresses caused by explosion pressure were not taken into consideration, and the thickness figured by the formula must be checked to be within safe limits to withstand this load. The calculation of the head thickness for strength is based on the supposition that the head of a piston is

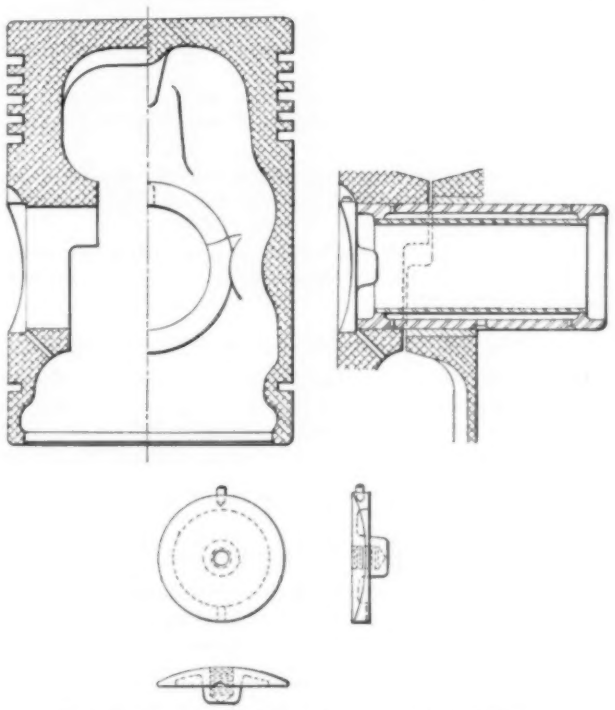

Fig. 5 Typical Design of Aluminum-Alloy Piston

a flat, round disk, supported around the edge and uniformly loaded.

The dangerous section of a flat, round disk will be along the diameter. This section is under the action of two bending moments acting in opposite directions. The first one is due to the explosion pressure and the second is due to the reaction forces of the supports (Fig. 3). The resulting moment is the algebraic sum of both and is equal to $M_B = \frac{D_1^3 \times P}{8} - \frac{D_1^3 \times P}{12} = \frac{D_1^3 \times P}{24}$. The section modulus of the flat, round disk with thickness t is equal to $\frac{D_1 \times t^2}{6}$. If S designates stresses, then $\frac{D_1 t^2}{6} \times S = \frac{D_1^3 \times P}{24}$, or $S = \frac{D_1^2 \times P}{4t^2}$ and $t = \frac{D_1}{2}\sqrt{\frac{P_{max}}{S}}$. Allowable stress for aluminum alloys should not exceed 5500 lb. per sq. in. If the t calculated for strength exceeds that calculated for thermal stresses, it is usually recommended to reenforce the head by a longitudinal rib of a depth in excess of t (strength) by $^1/_8$ in. (Fig. 4). The rib should be cast with as big radii as consistent with the size of the piston. This diminishes the high cooling stresses which are likely to occur with sharp changes of section.

Fig. 5 shows a typical design of an aluminum-alloy piston. As the details of the drawing are self-explanatory, it is sufficient to add only a few comments. Pistons are usually cast in semipermanent molds, that is, in metal molds having baked sand cores.

The chilling effect of the metal mold produces a hard, close-grained surface which insures long life for the thrust faces, ring grooves, etc. Further, pistons are heat-treated to attain hardness and strength and to remove casting strains, thus making a uniform product. In the following are summed up a few practical observations resulting from experience with aluminum-alloy pistons:

1 A large number of deep, narrow rings are better than a small number of shallow, wide rings of equivalent contact area.

2 A full-floating wristpin in combination with stepped-up bosses and wristpin plugs, as shown in Fig. 5, is preferred to any other type.

3 A stiffening rib cast around the skirt and between the wristpin bosses controls distortion and keeps the thrust faces round under all conditions.

4 A full-pressure lubrication of the wristpin bearing is desirable; aluminum wristpin plugs prevent an over-lubrication of the piston.

5 In many instances the clearances with which aluminum pistons can be operated are essentially the same as for cast-iron pistons.

Connecting Rods

From a consideration of Rankine's column formula, around which the design of connecting rods is usually built, it becomes apparent that considerable weight reduction can be attained when a steel rod is replaced by a rod made of strong aluminum alloy. The Rankine formula reads as follows: $S = \frac{P}{A} + 0.000526 \times \frac{P}{A} \times \frac{L^2}{R^2}$, where P is the total load on the rod, A is the area at the section of maximum stress, S is the allowable stress, L is the length of the rod, R is the radius of gyration of section. The first member of the formula, P/A, represents the compression per unit of area of the cross-section of the shank, and the second member, $0.000526 \times \frac{P}{A} \times \frac{L^2}{R^2}$, takes account of the additional stress due to the bending of the shank. R^2 is the ratio I/A where I is the moment of inertia of the section. This ratio is very flexible and is within the control of the designer. The moment of inertia depends upon the shape of the section and may have different values for the same area.

Allowable stresses in the case of plain carbon-steel connecting rods are approximately 18,000 lb. per sq. in. and approximately 24,000 lb. in the case of chrome-nickel steel. Allowable stress in aluminum-alloy connecting rods is approximately 12,000 lb. per sq. in. With a given P and L, the Rankine formulas for these three rods may be written as follows:

1 Carbon-steel rod: $\frac{P}{A_1} + 0.000526 \times \frac{P}{A_1} \times \frac{L^2}{R_1^2} = 18{,}000$

2 Chrome-nickel steel rod: $\frac{P}{A_2} + 0.000526 \times \frac{P}{A_2} \times \frac{L^2}{R_2^2} = 24{,}000$

3 Aluminum rod: $\frac{P}{A_3} + 0.000526 \times \frac{P}{A_3} \times \frac{L^2}{R_3^2} = 12{,}000$

It is evident that $A_1 > A_2$, and consequently the rigidity of the rod with area A_2 is impaired as compared with the rigidity of plain carbon-steel rods. An attempt can be made to restore the rigidity by increasing R^2, but this increases the rigidity only in the plane of motion with considerable loss of rigidity at right angles to the plane of motion. This indicates that an attempt to save weight by using special steels invariably leads to decrease in the rigidity of the structure. This is the result of the elastic modulus of steel being essentially independent of the composition, mechanical working, and heat treating of steel. In an aluminum rod the sectional area A_3 is bigger than A_2 or A_1 of steel rods. With increased area A_3, a designer has an excellent opportunity to shape the section for the best rigidity in both planes, having the considerations of clearance between the edges of the cylinder wall and rod as the only limiting factors against this ambition.

With a given P and L, the rigidity of the shank will be in direct proportion to the product of the elastic modulus of the material and the moment of inertia of the section. This indicates that in order to attain the same rigidity in the aluminum rod as in the steel rod, it is necessary to have the equation $E_{AL} \times I_{AL} = E_{ST} \times I_{ST}$.

As the elastic modulus of steel is three times greater than that of aluminum, this equation becomes $I_{AL} = 3 \times I_{ST}$. As the moments of inertia are in direct proportion to the fourth power of linear dimensions, it is evident that to satisfy the equation, it is necessary to increase the linear dimensions by $\sqrt[4]{3} = 1.316$ or 31.6 per cent, with consequent increase of area by $\sqrt{3} = 1.732$ or 73.2 per cent. From the consideration of specific gravities for forged aluminum alloy and steel (correspondingly 2.8 and 7.9), the apparent weight saving for the foregoing conditions becomes $\frac{7.9 - 2.8 \times 1.732}{7.9} = 38.6$ per cent. From the

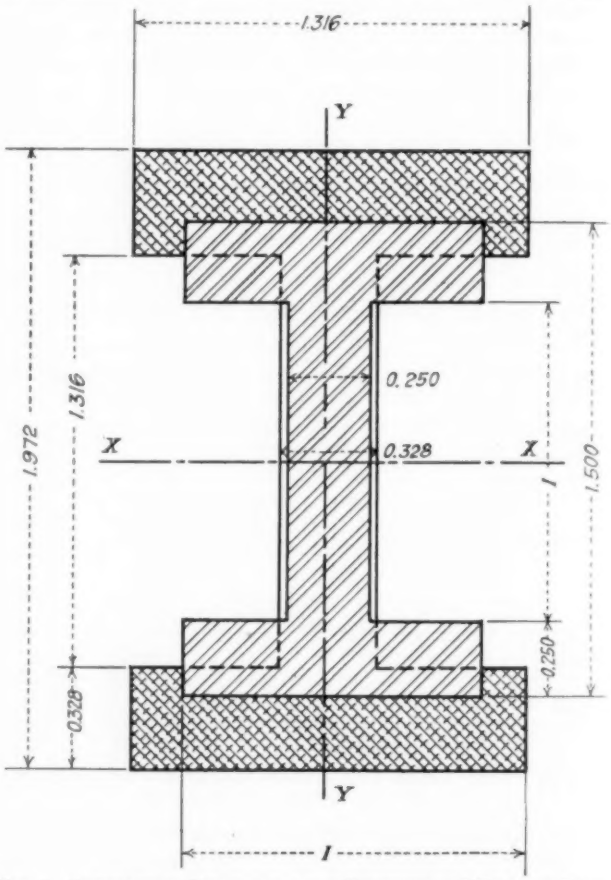

Fig. 6 Increase of Dimensions for Rigidity of I-Beam in Both Sections

	Area	I_{XX}	I_{YY}
Steel rod	0.750	0.219	0.043
Aluminum rod	1.297	0.655	0.129

$$\frac{\text{Area aluminum rod}}{\text{Area steel rod}} = \frac{1.297}{0.750} = 1.732$$

$$\frac{I_{AL}}{I_{ST}} = \frac{0.655}{0.219} = \frac{0.129}{0.043} = 3$$

example given in Fig. 6 proper increase of dimensions in the I-beam section for equal rigidity in both planes can be observed. Whenever there is no interference anticipated between the rod and cylinder wall, this change in cross-section is possible; otherwise, it requires less efficient metal distribution, with consequent increases of sectional area and weight. But even under the most unfavorable condition, the weight saving in the shank of the rod is nearly 30 per cent.

The weight saving in the wristpin and crankpin ends of the rod is considerably greater than is possible in the shank. This becomes evident from the following consideration: As the bearing width remains the same for aluminum and steel rods, the only possible change in dimensions will be an increase in the wall thickness. In this case the ratio $\frac{I_{AL}}{I_{ST}} = 3$ becomes equal to $\frac{t_{AL}^3}{t_{ST}^3}$, where t = thickness of wall.

This indicates that a necessary increase of thickness, in order to attain the same rigidity as in steel, will be $\sqrt[3]{3} = 1.442$ or 44.2 per cent, with a weight saving of nearly $\frac{7.9 - 1.442 \times 2.8}{7.9} =$ 49 per cent. From the foregoing considerations it becomes apparent that the total weight saving of 40 per cent in replacing the steel rod with aluminum is a very conservative estimate.

As the rules applicable to steel-rod design remain the same for aluminum, it will be sufficient to mention only a few suggestions, as follows:

1 It is necessary to avoid sharp corners in the machining or the spot facing of a recess for the bolt nut and head. Radius should be $^1/_{16}$ in. minimum (Fig. 7).

2 Direct babbitting of the big end of aluminum rod is given preference over that of steel or bronze-backed shells. A natural bond between babbitt and aluminum insures a very quick evacuation of heat from the bearing, and the bearing metal is more rigidly supported by the solid sections of the rod itself.

3 A bronze bushing with floating pin in small end of the rod.

4 Minimum draft angles 10 deg. in drop-forged rods.

Polar diagrams of big end-bearing loads for aluminum and steel rods are shown with a weight reduction of 40 per cent established in pistons and connecting rods where aluminum is substituted for iron. This is the case of a six-cylinder Diesel engine, $6^1/_2$-in. bore, $8^3/_4$-in. stroke, with a normal operating speed of 1000 r.p.m. This engine may be considered at the present time as belonging

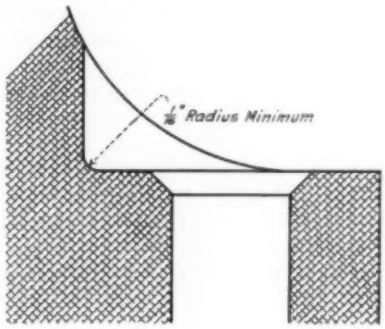

FIG. 7 MINIMUM RADIUS IN MACHINING RECESS

to the high-speed class. Improvements in fuel-injection methods, however, indicate that in the near future engines of this type may have the rotative speed increased to 1500 r.p.m. The complexity of thermal and mechanical difficulties arising from attempts to increase the engine speed and still preserve intact the reliability and longevity of parts common to slower speed engines will not be discussed here; therefore only the problem of bearing-load reduction in connection rods will be considered.

Table 1 indicates the comparative weights of iron and aluminum pistons and connecting rods and the weight reduction of the reciprocating and rotating masses thus effected.

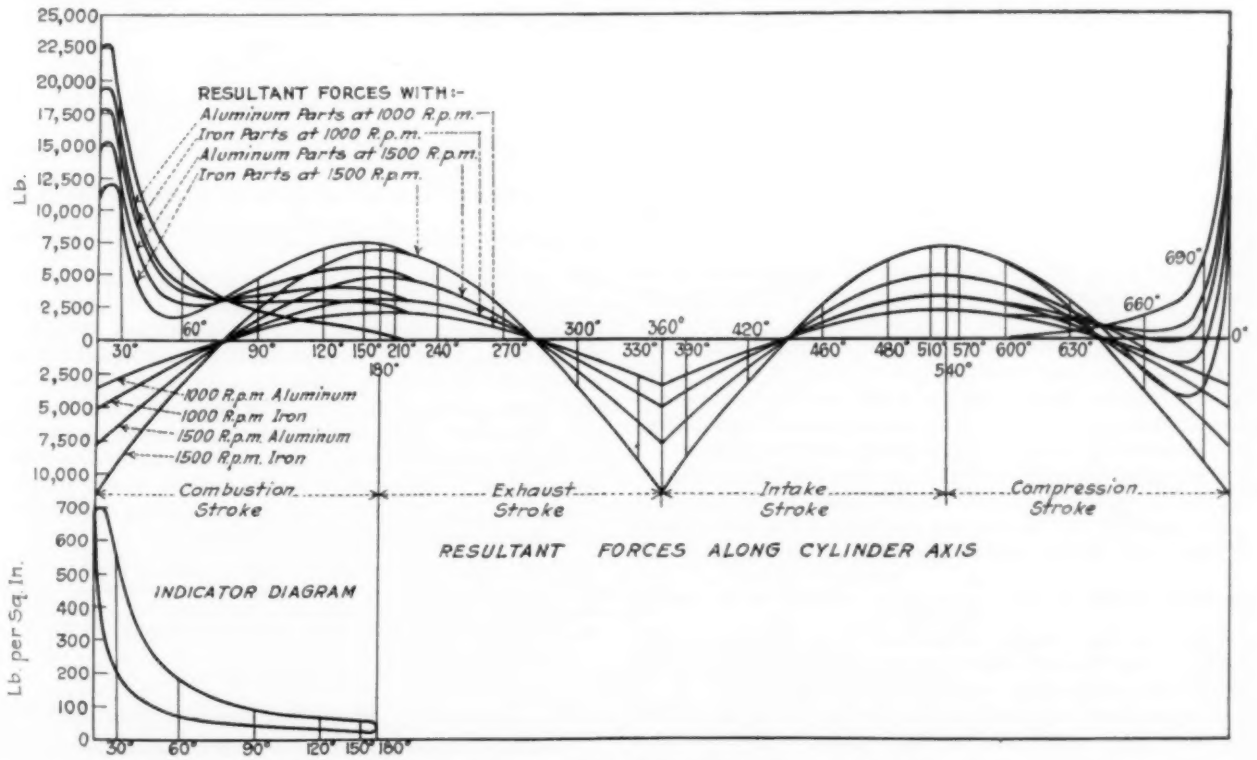

FIG. 8 DIAGRAM BASED ON THE COMPARATIVE FIGURES OF TABLE 1

TABLE 1

	Iron, lb.	Aluminum, lb.
Piston	22	11
Connecting rod	25	15
Total reciprocating weight	33.5	22.65
Rotating weight	16.6	10

The diagram, Fig. 8, was made by using the figures of Table 1 as a basis. The polar diagram, Fig. 9, compares unit bearing load and PV factor for both rods at 1000 r.p.m. Though bearing loads and PV are not very high at this speed for both steel and aluminum rods, it is of interest to note, however, that to get the same PV using aluminum rods as when using steel rods, the engine speed can be increased 10 per cent or up to 1100 r.p.m. (unit bearing load, 410 lb. per sq. in.; V = 18 ft. per sec.; PV = 7400 ft. lb. per sq. in. per sec.). At 1000 r.p.m., the normal rating of this engine is 180 b.hp. and it is safe to assume that at 1100 r.p.m. the output is increased in direct proportion with the increase of speed, or almost to 200 b.hp. The polar diagrams, Fig. 10, are prepared for the same rods in 1500 r.p.m. At this speed the advantage of lower unit bearing load and PV will be still more appreciated if the heat-dissipating ability of aluminum is also considered.

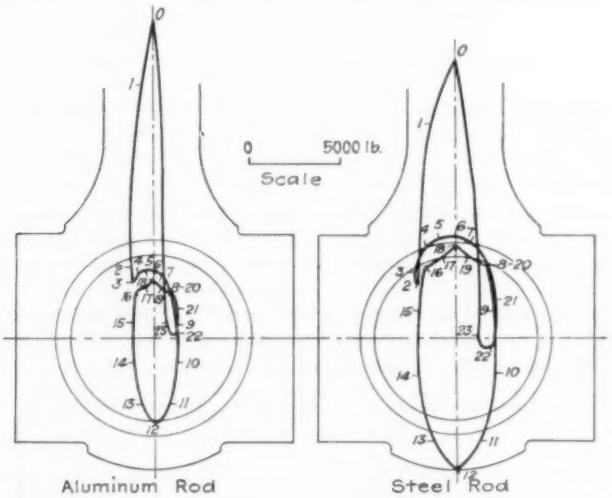

FIG. 9 LOADS IN BEARINGS OF ALUMINUM AND STEEL CONNECTING RODS AT 1000 R.P.M.

(Diameter of crankpin, 3.75 in.; projected bearing area, 11.5 sq. in.; rubbing velocity, 16.35 ft. per sec. For aluminum rod: Mean bearing load, 340 lb. per sq. in.; mean PV at 1000 r.p.m., 5560 ft-lb. per sq. in. per sec. For steel rod: Mean bearing load, 450 lb. per sq. in.; mean PV at 1000 r.p.m., 7350 ft-lb. per sq. in. per sec.)

If the PV value is not the limiting factor, as may be the case in some instances, quite often the consideration of critical speed sets the limit for speed increase. In this case the weight reduction in reciprocating and rotating masses again is very helpful, as it removes the range of critical speeds to higher values.

The critical speed of an engine occurs when the natural frequency of revolving masses coincides with the frequency of power impulses. In the case of a six-cylinder, four-cycle engine, if 1000 r.p.m. will be a critical speed, the natural frequency will be equal to 3000 per min. $\frac{F_1}{F_2} = \sqrt{\frac{W_2}{W_1}}$, where F is the natural frequency of the rotating system and W is the total rotating weight. This equation holds true only when the location of the node is not changed with change of rotating weight.

Weight reduction in reciprocating parts in the engine is 10.85 lb. per cylinder, or 65 lb. for the whole engine. Only half of this weight, or 32.5 lb., can be included when considering rotating masses. On the big end of the rod the weight reduction effected is 6.66 lb. per rod, or 40 lb. per engine. As this engine has a counterbalanced crankshaft, in order to preserve balancing, the same weight must be removed from the counterweights. This makes a total weight reduction in rotating masses of 112.5 lb.

As was shown, the natural frequencies for a given system are inversely proportional to the square root of the rotating weights ratio, and the new natural frequency with a weight reduction of 112.5 lb. will be equal to $F_2 = \frac{3000}{\sqrt{\frac{W_1 - 112.5}{W_1}}} = \frac{3000}{\sqrt{1 - \frac{112.5}{W_1}}}$. In the case of $\frac{112.5}{W_1} = 0.25$, which is very possible, as the total original rotating weight for this size of engine hardly could exceed 450 lb., the new frequency will be equal to $F_2 = \frac{3000}{\sqrt{0.75}} = \frac{3000}{0.866} =$ 3470 per min., or the engine speed can be safely increased to 1156 r.p.m. with corresponding increase in power. If PV and critical speed are not the limiting factors, and a speed of 1500 r.p.m. can be attained, consideration of the diagram of Fig. 10 will indicate that, for given conditions, the bearing in an aluminum rod will outlast that in a steel rod. The aluminum-rod bearing will run considerably cooler, not only because of a smaller unit bearing load and PV, but because of the superior heat-dissipating ability of aluminum. This results in cooler lubricant, which, retaining heavier body, separates two rubbing surfaces in a more efficient way, thus prolonging the life of the bearing.

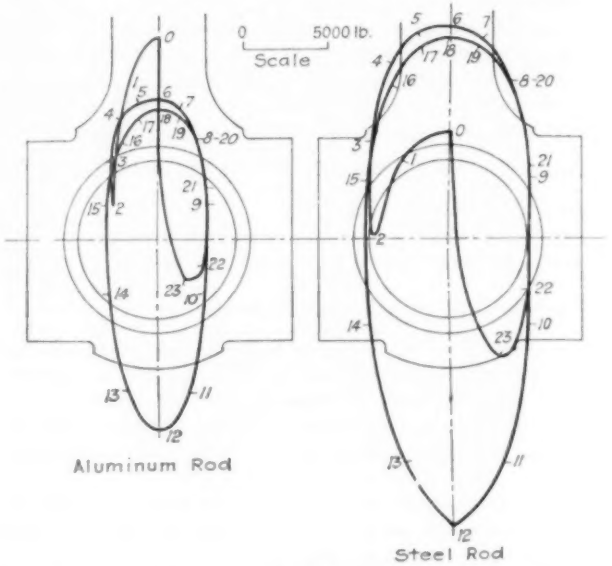

FIG. 10 LOADS IN BEARINGS OF ALUMINUM AND STEEL CONNECTING RODS AT 1500 R.P.M.

(Diameter of crankpin, 3.75 in.; projected bearing area, 11.5 sq. in.; rubbing velocity, 24.57 ft. per sec. For aluminum rod: Mean bearing load, 563 lb. per sq. in.; mean PV at 1500 r.p.m., 13,830 ft-lb. per sq. in per sec. For steel rod: Mean bearing load, 794 lb. per sq. in.; mean PV at 1500 r.p.m., 19,500 ft-lb. per sq. in. per sec.)

[NOTE: The derivation of the basic formulas, treated briefly in this paper, are explained in more detail in the author's paper, "Diesel-Engine Alloy Pistons, an Engineering Analysis," *Oil Engine Power*, vol. 7, nos. 7 and 9 (July and Sept., 1929), pp. 339–402 and 516–517.]

Discussion

B. J. ROBERTSON.[2] The author speaks of direct babbitting

[2] Associate Professor, Internal Combustion Engines, University of Minnesota, Minneapolis, Minn. Mem. A.S.M.E.

of the bearings in the big end of the connecting rod. What provision is then made to take care of the additional clearance in this bearing when it becomes hot? The coefficient of expansion of aluminum is approximately twice that of the steel in the crankshaft, which should produce excessive clearance when the bearing is hot or too tight a fit when the bearing is cold. Assuming 100 deg. fahr. temperature rise, the clearance of a 3-in. bearing would increase about 0.002 in.

Some automobile manufacturers use steel caps in combination with aluminum connecting rods to reduce the amount of expansion. Is this practice found necessary in heavy industrial engines?

Author's Closure

Steel bearing caps, as a measure of reducing the amount of expansion in the big end of aluminum connecting rods, are not needed in industrial engines. It has been found sufficient to fit this bearing with somewhat closer clearances than is customary in steel rods. A temperature range in bearings of industrial engines between the cold starting conditions (70 deg. fahr.) and the normal operating conditions (180 deg. fahr.) permits satisfactory and safe clearances to be obtained. The tendency of aluminum rod bearings to increase the clearances when hot is sometimes found to be beneficial as more oil passes through increased clearances, with considerable cooling effect on the bearing.

At the present time the use of aluminum connecting rods with steel caps has been confined to automobile engines, as here the temperature range in bearings may vary from sub-zero at starting to 250 deg. fahr. or more at operating conditions. The steel cap removes the trouble sometimes experienced with the all-aluminum rod, if initially fit too tight, of the freezing of the rods on the crankpins in sub-zero weather.

OGP-53-9

The Diesel-Engine Situation Today

By MAX ROTTER,[1] ST. LOUIS, MO.

The first commercially successful Diesel engines were a product of American manufacturers, but now large Diesels are being built principally in Germany. This country, however, is making considerable headway in manufacture of engines up to 1000 b.hp. per cylinder. The author discusses developments in atomization, combustion, and supercharging. He feels that there is now a need for standardization, but it must not interfere with progress.

IN 1898 the first Diesel engine in the world, to be put into commercial service, was built by Adolphus Busch and installed in the Anheuser-Busch brewery in St. Louis. Between that time and 1912, the Busch organization designed and sold the only Diesel engines built in this country. In 1912, when the Busch-Sulzer company started its new factory, this type of engine was being built, both here and in Europe, solely for stationary service, and when the plant was laid out, the engineers considered themselves quite optimistic when they set as the probable limit in engine size, a cylinder of 400 b.hp. and an engine of six such cylinders. Fortunately the overall dimensions and weight of this engine were determined on the basis of the then current piston speeds and heavy designs, so that the factory, as actually built, can turn out engines of more than three times the then estimated probable limit of power. These circumstances are mentioned to bring out the phenomenal expansion that has taken place in the intervening 18 years.

Today there is not one field of power generation and use that has not been penetrated by the Diesel, from the aeronautic engine to the large stationary engine of 15,000 b.hp. And by far the greatest and most rapid expansion has been in the application of the Diesel to marine propulsion, executed for the first time, in 1905, by Sulzer Brothers, in Switzerland, as a two-cycle, and in 1908, by Nobel, in Russia, as a four-cycle engine.

It is but fitting that this survey of the past include the recognition that is due, but has never been accorded to the American engineer who, at the very beginning, impressed his ideas upon the Diesel of two decades; namely James D. McPherson. It was he who designed the first trunk-piston type and the first multicylinder, vertical Diesels in the world; who developed a fuel pump and its governor control that are typical of those still being built; who showed, in his design of the combustion chamber, that he had a true understanding of penetration, diffusion, and turbulence that by many years antedated the adoption of these terms; and who installed the first Diesel engines in the world to run on coal tar, which they did successfully, for many years, in the plant of the United Gas Improvement Co. in Philadelphia.

McPherson's engines were the original type A, Busch-Sulzer. They were not as refined as modern designs; but 65 of them have been in regular operation more than 20 years; the dean being a 225 b.hp. engine, installed in Texas in June, 1904, and still going strong. It is worth noting that the fuel consumption of these early engines was about as good as that of quite modern Diesels, namely 0.42 to 0.43 lb. per b.hp.-hr. Incidentally, such records should serve to condemn the habit of many engineers, of estimating the useful life of a Diesel engine as 10 to 15 years.

It is a lamentable fact that Europe has now far outrun us although it was this country that in the beginning established the type for Diesel engines. Those who read trade journals that contain news of Diesel engines, cannot fail to be struck by the fact that we have not built a single stationary engine of over 4000 b.hp.; while, for example, Germany last year built two of 11,500 b.hp. each, and is building 5 stationary engines of 5000 b.hp. each for a single South American installation. In the marine field the comparison is still less pride-inspiring. Last year European countries completed 135 motorships of 3000 gross tons and over, with an aggregate propelling power of nearly 600,000 s.hp. of Diesels, only 3 of which ships were for American account; while we did not turn out a single such motorship, our output being limited to the conversion by the Shipping Board of 10 ships, of a little over 6000 gross tons each, with a total of less than 40,000 s.hp. Among the European-built ships are notable the *St. Louis* and *Milwaukee*, each of 17,000 gross tons, and each powered by 12,500 b.hp. in M.A.N. 2-cycle Diesels; also 3 ships for the New Zealand Shipping Company, each of 17,600 gross tons, and each powered by two 5000 b.hp., 5 cylinder, 2-cycle, Brown-Sulzer Diesels. And none of the foregoing figures include Japan, which last year completed the *Asama Maru*, of 16,500 gross tons and 15,000 s.hp., in 2-cycle Sulzer Diesels.

It would be ridiculous to assume from the foregoing that we, in this country, are incapable of producing large Diesels, equal to those built in Europe. We have always excelled in large things. In the sister industry we have designed and built the world's largest gas engines, which are operating successfully on leaner gases than are used anywhere in Europe. That the American Diesel industry generally turns to Europe for its large engine types, and restricts itself to adapting these to American methods and conditions, is natural, in view of the limited demand we have enjoyed, which has not justified the expense of independent development. Even our Navy has adopted a German design of submarine engine. One wonders whether our shipping industry is following the same fatuous course it did 70 years ago, when it lost its supremacy on the seas by clinging to the sailing clipper, of which it was justly proud, while Europe adopted the steamship.

While we are marking time in large Diesels, we have, in the past few years, proceeded very rapidly in engines of smaller

[1] Vice-President of Engineering Busch-Sulzer Bros.-Diesel Engine Co. Mem. A.S.M.E. The author was born in London, England, August 13, 1867. Educated in City of London School. From 1883 to 1888 he was apprenticed with Greenwood & Batley, Leeds, Eng., builders of steam engines and special machinery, while attending engineering courses of Governmental Science and Art Department, South Kensington, and of City and Guilds of London. From 1888 to 1891, draftsman for Maxim-Nordenfelt Co., Erith, England. He came to the United States in 1891, and worked as machinist with Browne & Sharpe; 1891 to 1894, chief draftsman for Walker Manufacturing Co., Cleveland; 1894 to 1911, first as draftsman and mechanical engineer for Fraser & Chalmers, Chicago, later as mechanical engineer, and finally chief engineer for Allis-Chalmers Company, Milwaukee, during which time made special investigations in Europe, as a result of which Allis-Chalmers Company took up manufacture of steam turbines and large gas engines. From 1911 to date, chief engineer, and since 1917 vice-president in charge of engineering for Busch-Sulzer Bros.-Diesel Engine Co., St. Louis, and doing private work as consulting mechanical engineer in Milwaukee. During World War, he supervised designing submarine engines for U. S. Navy.

Presented at a meeting of the Washington, D. C., Section, May 8, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

capacities. The Diesel locomotive is making headway in capacities up to 1000 b.hp.; the Diesel railcar is an established vehicle, the aeronautic Diesel has been perfected, and the automotive Diesel is coming to the fore. It is not egotistical to assert that we are doing more research work relating to liquid-fuel injection and combustion than any other country.

While the investigation of the processes of fuel injection is far from complete, and has unfortunately been confined to airless injection, we are learning the limitations of jet penetration and diffusion—knowledge that is vital in the design of large airless-injection engines. This explains why such large engines generally show mean pressures much below those attained in their smaller prototypes. At present, airless-injection engines with cylinder bores larger than 24 in. show mean indicated pressures below those attained with air injection; while in smaller engines the reverse is the case. These researches also explain the proved desirability of imposed turbulence in an airless-injection engine; and give a clearer understanding of some of the functions performed by the spray air of an air-injection engine, beyond that of merely spraying the fuel into the cylinder; namely, the creation of turbulence and the improvement of diffusion by the intimate mixing of air and fuel during injection, and the expansion of the spray air, as well as its jet velocity as it enters the cylinder.

Difference of opinions have developed concerning atomization and combustion, and, while some of them may be academic, they are interesting. As a matter of fact many will probably affect the design of Diesels as little as the theories of water-drop formation in the vapor affect the design of condensers. Little concerning atomization has yet been established beyond the fact that the drops of fuel break up as they travel through the compressed air. Undoubtedly a certain amount of atomizing is caused by the sudden expansion of the fuel, as it leaves the nozzle. After that, one theory is that the pressure against the leading side of the drop flattens it, until the fluid tension is overcome, and the drop breaks up; another, that the velocity of the drop creates a pressure reduction behind it, the drop assumes a streamline shape, and its trailing end is gradually triturated. Then there is the question whether vaporization or gasification precedes combustion, or the drop burns directly on its surfaces. Intricate calculations of flame propagation, which were inherited from gas-engine theories, seem to have been wasted effort. It may even be doubted that combustion proceeds according to the commonly accepted pictures; that is, accompanied by projected flames. Possibly it proceeds in the manner in which finely divided iron combines with oxygen, when introduced into it. That it is flame that issues from a cock in the cylinder may be due to the lower outside pressure.

The remarkable thing is that these processes can be accomplished in the time available for them, sometimes a little over two-thousandths of a second. Without practical demonstration this would seem to indicate the advisability of preventing the atomized fuel from striking a surface by which its combustion would be retarded until it is decomposed; nevertheless there is evidence that the drop may strike a hot piston surface and be broken up, the smaller drops rebounding from it, due either to their resilience or to the pressure of vapor formed under and within them, as a drop of water explodes on a hot stove lid. Likewise, the drops of fuel should not collide, unless while their velocity is still high enough to disrupt them, and before it is low enough to allow them to coalesce.

In conjunction with questions of fuel injection in Diesel engines, it is interesting to consider that of excess air; that is, the large percentage of the air, contained in a cylinder, that is not required for the combustion of the fuel. This excess air is generally about one-half of the total, sometimes nearly two-thirds, and rarely less than 40 per cent. The natural snap judgment is to ascribe this to lack of perfection in the fuel-injection process, and to assume that perfecting the process would afford some of the advantages now attained by supercharging. While it may be true that, even if it were desirable, we are not yet able to consume a greater proportion of the air and attain smokeless combustion; it is doubtful that we could, at this date, go much farther in that direction, being limited by the temperature resistance of available materials; and it is equally true that we could not attain anywhere near the complete utilization of the oxygen, without a substantial loss in overall efficiency, and without an increased engine cost. Ordinarily the air, in a Diesel cylinder, is compressed to about $6^1/_2$ per cent of its original volume, attaining a pressure of 480 lb. absolute, and a temperature of 880 deg. fahr.; in this air is burnt a given weight of fuel, say at normal engine load about one-half of the weight for which the air could supply the necessary oxygen, the volume of air and gases expands to about $2^1/_2$ times the original volume of compressed air, with little increase in pressure but with an increase in temperature to about 2700 deg. fahr. The air and gases then expand about $6^1/_2$ times in volume, and to a pressure of about 50 lb. absolute, performing work equivalent to a mean indicated pressure of about 115 lb. per sq. in. of piston area. Should 50 per cent more fuel be burnt in the same quantity of air, the temperature at completion of combustion would increase to at least 3700 deg. fahr., too high for ordinary present-day materials and design. These conditions do not exist in a properly proportioned supercharged engine in which the air excess is considerably greater than in a non-supercharged type.

Supercharging, by which is understood the artificial increasing of the weight of combustion air with which the cylinder is charged before the fuel is injected, is gaining some adherents. Witness the propelling engines installed by Harland & Wolf in the motorship *Llangibby Castle*, each engine normally rated at 3200 b.hp., and capable of developing 4250 b.hp. when supercharged.

The general idea of supercharging is quite old; 20 years ago Sulzer Bros. were experimenting with it, but were turned aside temporarily by more urgent lines of development, such as the two-cycle engine.

There are several systems of supercharging. The best known are the Rateau and the Buechi, both of which provide the supercharging air by means of centrifugal blowers, driven by turbines using the exhaust gases of the engine as motive fluid. In general, these systems are similar to that developed in this country, under Dr. Moss, of the General Electric Company, for supercharging the gasoline engines of aircraft, to maintain sea-level air conditions in the engines, at high altitudes and thus enable the engines to carry almost full load regardless of the rarified atmosphere. As stated before, by proper adjustment of the compression ratio and the air excess, these supercharged engines are not subjected to higher temperatures or higher maximum pressures than those existing in similar normally charged engines; although, of course, the average cylinder pressures are higher. The pressure of the supercharging air is about equal to the pressure of the exhaust gases, generally 18 to 20 lb. absolute; and the capacity increase of the engine, 30 to 40 per cent.

In the Buechi system the speed of the blower and therefore the pressure of the supercharging air automatically adjust themselves to the existing engine load, due to the variation of the exhaust pressure with the load. The result is high efficiency, and a very flat fuel-consumption curve. This system is, therefore, suitable for continuous operation. To date it has been applied exclusively to four-cycle engines; although it might well be applied to certain two-cycle types. The reason why the latter has not been done lies in conflicting patent interests.

Distinguished from the former systems of supercharging, intended as a regular condition of operation, is the Sulzer system

intended primarily to increase the overload capacity of a two-cycle Diesel engine. In this system the supercharging air is furnished by a compressor, attached to the engine, which compressor comes into and goes out of action under control of the engine governor, so that supercharging takes place only at the higher engine loads. The automatic valves in the upper tier of the Sulzer scavenging ports for the normal scavenging and charging are supplemented by timed valves, controlling the delivery of supercharging air to the cylinder, so that the latter air, furnished by the supercharing compressor, is admitted only toward the end of the charging period; that is, after the piston has covered the exhaust posts, and before it covers the upper scavenging ports. With this arrangement the capacity and power consumption of the supercharging compressor are reduced to the minimum. The capacity of the engine may temporarily be increased as much as with the Buechi system; but the fuel efficiency of the engine is adversely affected to the extent of about 5 per cent, due to the power consumed by the supercharging pump, even when not in action. However, it is an inexpensive means to increase the peak capacity of an engine, and when the available space does not permit the installation of a larger engine.

Still another system of supercharging has been applied to certain German four-cycle engines, for the same purposes as accomplished by the Sulzer system. In this system also, the supercharging air is furnished by a compressor attached to the engine. In addition to the normal admission valve, a timed supplementary piston valve is provided, which gives access of atmospheric air to the admission valve during the earlier portion of the suction stroke, and of supercharging air during the later portion of the stroke. This, as in the Sulzer system, reduces the dimensions and power consumption of the charging compressor, below what they would be if all of the charging air were furnished by it; but it, too, increases the fuel consumption at all loads.

As in the Buechi system, the compression and air excess in the Sulzer and German supercharged engines are adjusted so that the combustion temperatures will be substantially the same as in the un-supercharged engine. The process of scavenging, that is, clearing the cylinder of the products of the previous combustion, has a close relationship to supercharging, and is receiving considerable attention.

The scavenging of a four-cycle engine is an obvious process. When the exhaust valve is opened, the major portion of the products of combustion are expelled from the cylinder by their expansion; the remainder is pushed out by the piston. This necessitates opening the exhaust valve against the terminal pressure in the cylinder, about 35 lb., requiring rugged valve gearing. Attempts have been made to reduce this work by providing exhaust ports, uncovered by the piston near its outer dead center, but the complication of this construction has not been justified by its advantages. A recent invention provides a smaller relief valve, within and opening in advance of the main exhaust valve, but it is almost a foregone conclusion that this, also, will not be worth while.

The scavenging of a two-cycle engine is a more difficult problem, including, as it does, the simultaneous recharging of the cylinder. These processes must both be accomplished in 40 to 50 deg. of crank travel, as compared with 360 deg. available for the same, in a four-cycle engine. Moreover, the process is not a definite mechanical one, as it uses air to displace the spent gases, and it has therefore been and still is the subject of considerable experimentation, including, as it does, the creation of the desired character of turbulence. All such experiments suffer from the same limitations. They are made with a substantially constant stream of air, through a constant cylinder volume, against a constant pressure, through constant openings, without disturbing mechanical motions within the cylinder. They have been of value, however, in pointing the direction of "cut-and-try" experiments, but can scarcely be considered as more than remote indications of processes that are complicated by the variation in pressures, and stream velocities and directions, caused by the progressive uncovering and covering of ports by the piston; by the variable cylinder volume; and by the already existing turbulence of the gases due to their expansion and outflow. Every catalog picture, illustrating a scavenging system, shows clean-cut curves and loops, embellished with arrowheads, sometimes in two colors, red for the hot exhaust gases, blue for the pure cold air, which indicate what might reasonably be expected if the cylinder were a vertical slice through a hemisphere, with a scavenging port to the east, and an exhaust port to the west.

It does not appear that any Diesel designer has yet attempted to scavenge and charge a two-cycle cylinder through exhaust and scavenging valves, both in the cylinder head. All other combinations include piston-controlled ports, either for exhaust, or for scavenging, or for both. Most of the earlier two-cycle engines exhausted through ports and admitted scavenging air through valves in the head; but this arrangement has been almost universally abandoned. Reversing the process, we now find the new B. &. W. two-cycle, double-acting engine admitting scavenging air through piston-controlled ports, and exhausting through timed valves in the cylinder heads. This, including the use of the exhaust valves as supplimentary power pistons, is decidedly the most novel development of last year, and the performance of the engine in the *Amerika* will be watched with keen interest. Its reported efficiency and capacity are remarkable for a double-acting, airless-injection engine.

The simplest arrangement has been most generally adopted, piston-controlled ports for the scavenging air around one-half the cylinder circumference, and the same for the exhaust around the opposite half, but in at least one construction the scavenging and exhaust ports alternate around the whole circumference. Usually the exhaust ports are first uncovered by the piston, and the scavenging ports somewhat later, the interval being sufficient to allow the pressure in the cylinder to fall below that of the scavenging air. This arrangement affords the least time for charging, and under certain conditions allows exhaust gases to blow back into the cylinder. An improved condition is obtained, in engines like the Fiat and Setz, by locating the edges of both scavenging and exhaust ports so that they will be uncovered simultaneously, and providing the former with inwardly opening valves. Neither of these arrangements enables the charging of the cylinder to a pressure higher than the exhaust back pressure; in fact, the eductor action of the exhaust may cause an under-pressure in the cylinder charge. There are examples of increasing the back-pressure, by throttling the exhaust, but this is liable to affect the scavenging adversely, and should be resorted to only to assist in equalizing the work among the several cylinders.

The arrangement that most nearly fulfills the desired conditions is that developed by Sulzers, and improved by Reale, in which the scavenging ports are arranged in two tiers, the upper being provided with automatic inwardly opening valves, and being uncovered before and re-covered after the exhaust ports, thus providing the maximum time for charging.

A marked tendency at this time is toward airless injection. Although this system has long been in use on engines of smaller capacities, and has been applied to large engines, by M.A.N. occasionally, by Doxford more extensively, and with marked success in the A.E.G.-Hesselman engine, its more general use in large engines has recently increased notably. A comparison of the performance of air injection and airless quickly dispels the former common belief that the efficiency of the airless is

higher to the extent of the power consumed by the injection air compressor, which consumption has ordinarily been stated to be 10 per cent of the power developed by the engine. The average airless-injection engine actually consumes only about 5 per cent less fuel than an equivalent engine with air-injection.

The injection of 1 lb. of fuel requires about 20 cu. ft. of free air, compressed to 800 to 1000 lb. pressure. If these quantities are considered as being per minute, they would apply to an engine of about 150 b.hp.; and the compression of the spray air would consume about 10 b.hp. In ordinary practice, adjustments are not made so closely, and the compressor load may readily be 50 per cent higher than this, apparently justifying the stated consumption of 10 per cent. The spray air is compressed in three stages, and cooled to about atmospheric temperature before it reaches the fuel valve. Thus the conditions are, roughly, that air at say 900 lb. pressure and atmospheric temperature in the fuel valve, enters the power cylinder with a pressure drop to say 475 lb. There its temperature is raised by the compressed air in the cylinder, to about 840 deg. fahr. From this point the spray air acts as part of the compressed-air charge in the cylinder, expanding and performing work on the piston, just as does the air compressed in the cylinder itself, whether the injection be by air or airless. The actual power chargeable to the compressor is, therefore, its friction (say $2^1/_2$ hp.), plus the power consumed in compressing the spray air from 475 to 900 lb. (say $1^1/_2$ hp.); this sum, liberally figured, is thus less than 3 per cent of the net engine output. The weight of the air in the compressor space of the engine is about 30 lb. per pound of fuel, and its temperature, as stated, about 880 deg. fahr. before being cooled by the injection air. The acceleration and atomization of the fuel consumes about the same power as in an airless-injection engine, say $^3/_4$ hp. per lb. of fuel per min., and the temperature of the whole cylinder contents is reduced about 40 deg. fahr. To overcome this and place the engine on a par with airless injection, the compression in the power cylinder of the air injection is increased about 20 lb., adding to the work of compression about $2^1/_2$ hp., which is absorbed by the cooling effect of the spray air. Thus, the total power consumption, in such an engine, chargeable to air injection, ranges from $6^1/_2$ to 8 hp., or about $4^1/_2$ to $5^1/_2$ per cent of the engine capacity.

The foregoing accounts for the difference in fuel consumption, and the higher compression usual in air-injection engines. The figures are, of course, subject to modification according to the size of the engine, and the commercial value of the saving must be adjusted to the prices of the fuels that may be used successfully in the respective engine types. It must not be assumed that the higher efficiency, simplification, and reduced first cost of the airless-injection engine are gained without some sacrifice in ability to use fuels that may be cheaper, and this disability may become important if and when liquid fuels other than petroleum, shall be produced to sell at prices below those of petroleum, and this is not an unlikely development.

Other tendencies in construction and arrangement, some of which may be overstepping the desirable limit, and about each of which much could be said if time would permit, are the double-acting engine; Diesel-electric propelling engines, as installed in the coverted American ships *Triumph*, *Courageous*, and *Defiance*, a type of propulsion that has not found favor in Europe; Diesel-geared propulsion, as installed in a number of large European ships, including the recently commissioned *St. Louis* and *Milwaukee*, with 12,000 s.hp. each, and the much discussed *Ersatz Preussen*, with 50,000 s.hp.; but in only one moderate-sized American ship, the *Herman Falk*, with 2600 s.hp. There is also the composite steam turbine and geared Diesel installation, in a naval cruiser, in which the center propeller, consuming 12,000 b.hp. will be Diesel driven, to obtain high efficiency and long radius of action at the ordinary cruising speed of 18 knots and in which the two outboard propellers, each consuming 30,000 b.hp., will be driven by steam turbines, to enable a ship speed of 32 knots when necessary.

It is natural that in an industry that has grown to the magnitude of Diesel manufacturing, there should be an urge toward standardization, and standardization confined to proper channels is most desirable, but it must not overflow into domains in which it would retard progress, or discountenance efforts toward improvement. For example, it is clearly most desirable to standardize the form and dimensions of articles, also the composition and properties of materials, if such articles and materials are extensively used, but it is most undesirable to standardize the application and conditions of use and service of such articles and materials. Where would the steam-turbine industry be if the speed, steam pressure, and steam-temperature conditions had been standardized or limited 25 years ago, leaving no incentive for engineering skill and metallurgical research, beyond that of endeavoring to reduce the cost of manufacture? Standardization must not be such as will abridge the effort to improve, as well as to reduce cost, by skillful design and the intelligent selection of materials. The recently suggested limitation or standardization of Diesel-engine ratings, on the basis of mean indicated pressures, would appear to come within this proscribed territory. This limitation has been predicated on the theory that the Creator gave us certain materials, which possess definite properties; it must not be overlooked that He gave us also brains to modify such properties by combinations and treatment of such materials, and to select materials according to their intended use and service. Consider, for instance, the piston head of a Diesel. It may be well designed or poorly designed; it may be cooled or uncooled; it may be made of ordinary or special-alloyed cast iron; of forged or cast carbon or alloyed steel, or of aluminum or magnesium alloys; and superimposed on this choice of materials are infinite variations in molding, casting, and heat treating. In addition to which, every change in diameter and rotative speed presents changed problems. To require the application to all of these of a single rule, based on temperatures, is not reasonable.

A maximum basis of rating is not a protection for the purchaser. Its acceptance will not ensure good judgment or honesty, any more than constitutional amendments and laws ensure abstemiousness and chastity. As in these, the violators will discount the probabilities of being caught, and there are conditions of service, such as marine propulsion, in which the actual power consumption cannot be readily established. A maximum rating is likely to be a standard rating, when the conscience is flexible; whereas the rating of an engine should express the work that particular engine may be depended upon to perform, with safety and reasonable wear, and with a fair margin to allow for possible improper adjustments, with due regard for the available opportunities for correcting them. For this reason, Busch-Sulzer, for example, establish from 3 to 5 distinct ratings for one and the same engine, the highest being for stand-by service, in which the engine may operate only a few days in the year; the lowest for single-engine ocean-going ship propulsion.

The variety of the bases of rating, proposed by British engineers, indicates the complexity of the matter. For example, they have suggested that the rated normal capacity of an engine be the power it will develop continuously for 12 hr. (presumably with invisible exhaust), and that the continuous rating be 10 per cent below this; but they apparently recognize the deficiency of this method by limiting it to engines for driving electric generators. It has also been suggested that the ratings be fixed at established percentages below the stalling torque, or the load at

which the engine definitely begins to drop its speed; but this torque and load will vary considerably with the immediate condition of the engine, the character of fuel, lubricating oils, and atmospheric conditions. And neither of these methods differentiate between different qualities of engines; nor does the third European suggestion that the rating be a definite percentage below the maximum load the engines will carry with smokeless exhaust.

The recent American proposal to limit Diesel ratings to certain maxima in mean indicated pressures, assumed to reflect maximum permissible temperature stresses, is unsatisfying for the previously stated reasons, and, furthermore, selects a criterion that is confessedly unreliable, excepting in slow-speed engines, but which it proposed to apply to engines of speeds up to 800 r.p.m. It would appear more logical to limit the amount of fuel burned per minute per square inch of piston area, but this is not being advocated in this paper. It is rather the writer's belief that so long as the majority of purchasers compare engines on the basis of price per horsepower, per pound, and per cubic foot of cylinder volume, which latter, by-the-way, a purchaser recently did without considering that he was comparing a four-cycle with a two-cycle engine, it is each builder's job to justify his own rating, as applied to his engine for the contemplated conditions of service.

The foregoing leads to another question: What is the m.i.p. of a four-cycle engine? This is important, in view of the practice of many consulting engineers of limiting this pressure and requiring a guarantee of brake efficiency. That such limitations and guarantees are of little value, without qualifications that would practically specify the make of engine, is beside the question. The purpose of the practice is obviously to limit the temperature stresses at the specified useful power output. Therefore, the method of measuring the m.i.p. should be such that this pressure will truly reflect the temperature conditions.

In a four-cycle indicator card, the bottom loop area represents the work of pushing out the exhaust gases and drawing in the air charge. The more inadequate the valve areas and ports, the larger will be this work, and, if the area representing it be deducted from the upper diagram area, to determine the m.i.p. and brake mechanical efficiency, the poorer the engine design the greater will be the area of the upper diagram for the same m.i.p. and efficiency, and the higher the temperatures. Moreover, the bottom loop represents the same work as is performed by the scavenging pump of a two-cycle engine, yet it would be entertaining to hear the remarks of the purchaser's engineer if the builder of a two-cycle engine were to deduct the mean pressure calculated from the scavenging pump diagram from the mean pressure of the power-cylinder diagram in establishing his m.i.p. and brake mechanical efficiency, although there is little difference between the work consumed by the scavenging pump of a well-designed two-cycle engine, and that consumed in the exhausting and charging of a less well-designed four-cycle, and there is a substantial cooling effect exercised by the large volume of scavenging air passing through the two-cycle cylinder.

The Quiescent Combustion Chamber

By JOHN A. SPANOGLE,[1] HAMPTON, VA.

The term "quiescent" is originated as describing more accurately than "non-turbulent" the condition of the combustion chamber in some fuel-injection engines at the time of injection of the fuel. Such a combustion chamber is considered quiescent if the movement of the air has no appreciable effect on the distribution of the fuel to the air with which it must unite during the process of combustion. Performance tests of a single-cylinder unit furnished the material for the paper, in the general program of the National Advisory Committee for Aeronautics in investigating the compression-ignition, fuel-injection engine as a source of power for aircraft. The simplest combustion chamber is the quiescent one, and the simplest injection orifice is the round hole; and the main tests were directed toward obtaining the optimum combination of these two elements.

ANY discussion of the compression-ignition, fuel-injection engine is hampered by the lack of general acceptance and universal use of descriptive terms for the elements and functions of elements which are incorporated in this type of engine. Descriptive adjectives for combustion chambers denoting the conditions of air flow therein have not as yet come into general use for the fuel-injection engine, although the authorities on the carbureted engine seem to be generally satisfied with the use of the respective terms "turbulent" and "non-turbulent" for combustion chambers with and without certain kinds of air flow. The use of the term "turbulence" in this sense is by definition (deviation from mean velocity) apparently unsuited for use by any one connected with aeronautics. In addition to this objection, there is also the thought that turbulent flow is not suited to the requirements of the fuel-injection engine and that better results may be obtained if the air flow is entirely orderly and reproducible for every individual engine cycle.

This consideration discourages the use of the opposite term "non-turbulent," and in casting about for another properly descriptive term with the requisite background, it was found that there are objections to all such terms in common use. Therefore it was decided to use an adjective that is without definite engineering precedent, but which describes the condition of the combustion chamber at the time of injection of the fuel in a manner that is satisfactory but not necessarily ideal. Any combustion chamber for a fuel-injection engine is considered "quiescent" if the movement of the air in this combustion chamber has no appreciable effect on the distribution of the fuel to the air with which it must unite during the process of combustion.

The material in this discussion was obtained from performance tests of a single-cylinder test unit with a combustion chamber that seems best suited to operation without effective air flow. The work was done by the staff of the National Advisory Committee for Aeronautics at the Langley Memorial Aeronautical Laboratory in the course of the general program for investigating the possibilities and limitations of the compression-ignition, fuel-injection engine as a source of power for aircraft. This type of power plant has well-known, inherent advantages which make it particularly desirable for aircraft service, but the requirements for this service are so rigid that these natural advantages cannot be made available unless the performance of the compression-ignition, fuel-injection engine can compare favorably with that of the carbureted gasoline engine.

The cylinder head of the engine used in these tests is not necessarily ideal and probably has disadvantages for commercial

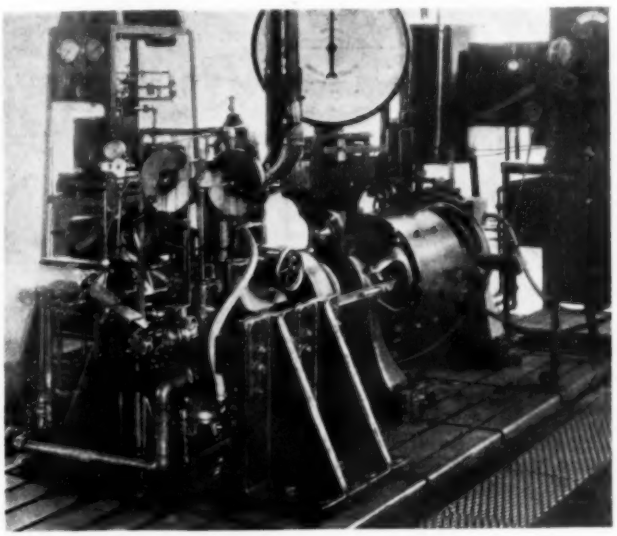

FIG. 1 SINGLE-CYLINDER ENGINE USED AS A TEST UNIT

production, but it is a convenient design from the standpoint of an investigator and can be considered as satisfying the requirements for a quiescent combustion chamber when used as such. To justify the investigation of the quiescent combustion chamber when design trends seem to show the increasing popularity of the use of air flow in combustion chambers, there are the examples of several sciences, notably biology, in which it is possible to learn much from the study of simple types before going on to the higher, more complicated forms. The simplest type of combustion chamber is naturally the quiescent combustion chamber, and the simplest injection orifice is the round hole. These two forms are the basis of this investigation, and the main series of tests were directed at the determination of a method for obtaining the optimum combination of these elements. In the course of this work some other investigations have been conducted on this test unit, but they may be considered as interesting digressions from the main investigation.

[1] Assistant Mechanical Engineer, National Advisory Committee for Aeronautics, Langley Field. The author was graduated from Pennsylvania State College, Department of Mechanical Engineering, with B.S. degree, 1917; First Lieutenant, Coast Artillery Corps, U. S. Army, 1917; Aerial Observer, U. S. Air Service (A.E.F.), 1918; Proof Officer, Aberdeen Proving Ground, Maryland, 1919; retired from active service, 1920; building construction, Washington, D. C., 1921 to 1927; Assistant Mechanical Engineer at the Langley Memorial Aeronautical Laboratory, November, 1927; head of Engine Research Section at Langley, April, 1929, to date.

Presented at the National Oil and Gas Power Meeting, University of Wisconsin, Madison, Wis., June 23–26, 1931, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Apparatus

The test unit used in this work is shown in Fig. 1. It includes the engine connected to an electric dynamometer and the necessary auxiliaries and apparatus for securing the performance data. The parts of the engine are, as far as practicable, the same as those of the N.A.C.A. universal test engine, the main exception being the cylinder head, which is designated in our test series as N.A.C.A. cylinder head No. 4 and has a vertical disk-shaped combustion chamber formed between the heads of horizontally opposed intake and exhaust valves, as shown in Fig. 2. This cylinder-head arrangement makes it possible to have three alternative positions for the fuel-injection valve and the pressure elements of the various cylinder-pressure measuring and recording devices. Another feature of this cylinder head is the removable orifice between the cylinder and the valve chamber. The clearance between the piston crown and cylinder head was from 0.030 to 0.040 in. at top center.

The fuel-injection pump was the usual cam-actuated plunger pump with injection controlled by a bypass valve. The plunger displacement was much greater than was necessary for injecting full-load fuel quantities, and the cam gave the plunger a variable

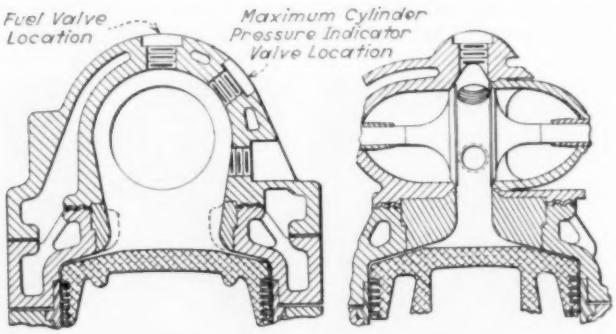

Fig. 2 Combustion Chamber

velocity throughout its stroke, so that by varying the settings for the closing and opening of the bypass valve, different rates of plunger displacement could be used for injecting the fuel. The pump was driven from the crankshaft through a reduction gear in which there was an adjustment for changing the angular relation between the crankshaft and the pump cam. Different fuel-injection valves were used, but they all were of the same general type, having spring-loaded stems hydraulically controlled. The pump and valve were connected by a steel tube 36 in. long and $^1/_8$ in. inside diameter.

The electric dynamometer was used to absorb the engine power and to motor the engine for starting and for the friction runs immediately after the power runs. The stop watch and revolution counter were actuated electrically. Fuel and air consumptions were determined by timing the displacements of 0.5 lb. of fuel and 80 cu. ft. of air. Water and oil temperatures (out) were maintained at 170 and 140 deg. fahr., respectively. The temperature in the air intake was 95 deg. fahr., except during supercharging.

Compression pressures and maximum cylinder pressures were indicated by a Bourdon spring gage in connection with a trapped pressure indicator for most of the tests, but toward the end of the investigation the balanced-diaphragm apparatus was used. Indicator cards were taken with the Farnboro electric indicator during the course of its remodeling at the Langley Memorial Aeronautical Laboratory, and the accuracy of the cards increased as the test work progressed. The cards presented may be considered sufficiently accurate, since the i.m.e.p. as determined from the area of the P-V diagram is within 5 per cent of the sum of the b.m.e.p. and the f.m.e.p., although the summation was used in plotting indicated performance curves. Any values presented may be considered average and readily reproducible.

Single-Stem Fuel-Injection Valve

The first idea which governed the design of fuel-injection nozzles for this cylinder head was that the sprays should not have penetration enough to reach the boundaries of the combustion chamber. It soon became apparent that restricting the sizes of orifices to reduce penetration also prevented enough fuel from being introduced into the engine in a sufficiently short time for high-speed operation even with undesirably high pressures in the injection system. The idea of restricting penetration was therefore abandoned, and a series of tests was started to determine, by actually varying the sizes of orifices systematically, the optimum size for each orifice in a seven-orifice nozzle.

The main orifice diameters were varied from 0.010 to 0.021 in., and best performance was obtained with the 0.018 in. diameter, although an inspection of carbon deposits on the piston showed that actual impingement started with the 0.012-in. orifices. Of course, some excess fuel is necessary to take care of the combustion air in the clearance between the piston crown and the cylinder head, but the surprising part of these data is that the power increases and the fuel consumption decreases consistently up to a diameter of 0.018 in., indicating that the distribution of fuel to the air is not impaired but actually improved by this impingement on the piston crown.

After the optimum size for the main orifices had been determined, the outside orifices were varied, and although the power increased up to a diameter of 0.012 in., it was decided to maintain these orifices at 0.010 in. diameter because the smokier exhaust did not warrant the utilization of the small increase of power available with the 0.012-in. orifices.

Enlarging the intermediate orifices decreased the power, and this decrease was rather hard to explain until spray photographs were taken inside a dummy combustion chamber. These spray photographs showed that the large outer sprays were hitting the combustion chamber walls and rebounding into the space which probably was not reached by the short intermediate sprays. Therefore it seemed quite likely that when these intermediate sprays were enlarged they merely put more fuel into air that was also being served by the outer orifices.

Even before these spray photographs had been taken a line of reasoning had indicated that it would be advisable to try a nozzle based on the proper mixing of the fuel and air by metering the fuel directly to the air and neglecting entirely any air flow, especially as work with air flow in a simulated combustion chamber had indicated that the actual velocities encountered were too low to affect the penetration and distribution of the oil sprays.

The basic assumptions on which this line of reasoning depends are that air flow is ineffective in this combustion chamber, that the coefficient of discharge of all orifices in a multiple-orifice nozzle will be the same, and that the pressure effective in causing the discharge will be the same for all orifices. These assumptions seem reasonable, and all factors determining the discharge of an orifice should be identical except the orifice area. If, then, these orifice areas are in the same proportion to the total discharge area as the volumes of air they serve are to the total volume of air served, the homogeneity of the resulting mixture of air and fuel is dependent upon the dispersion of the fuel in the spray and the shape of the volume served.

This proportional principle of course requires some orifice area as a starting point, and it was decided for the sake of comparison with previous data to adopt the two main 0.018-in.-

diameter orifices which seemed to be better established as an optimum than the other orifices. When calculating the air volumes to be served, the air in the clearance between piston crown and cylinder head was considered to be served by these main sprays. The spray angles as used in the previous nozzles were continued in these nozzles, and two more orifices were added on each end of the line, making a total of nine in one plane. There is nothing either in the performance data or in spray photographs to indicate that these orifices discharged enough fuel to make any difference in performance, and therefore their addition is considered an unwarranted complication. It is possible that when entering at an angle in the flow passage, as they do, they do not have the same effective discharge pressure as the other orifices.

The first nozzle in this C-series was built without the center, filler orifice, in an attempt to determine its value. This value was quite evident from the increase in the engine performance with the center spray and at the time was attributed solely to the fact that the greater part of the fuel in the main sprays traveled through the space they were supposed to serve and left but little fuel in the first few inches, thereby presenting the opportunity for the center spray of shorter range to serve the air in this space and improve the engine performance.

The work with the C-series of nozzles confirmed the proportional principle in a satisfactory manner; so it was decided to discard the original angular spacing and try to find out just how far it was necessary to follow this proportional principle for good performance. Spray photographs were consulted, and as the spray-cone angles for sprays under comparable conditions, except temperature, varied from 18 to 22 deg., an angle of 20 deg. was adopted, and a nozzle was designed which would have a total of 16 orifices in three planes, with an angle of 10 deg. between planes, as shown in Fig. 3.

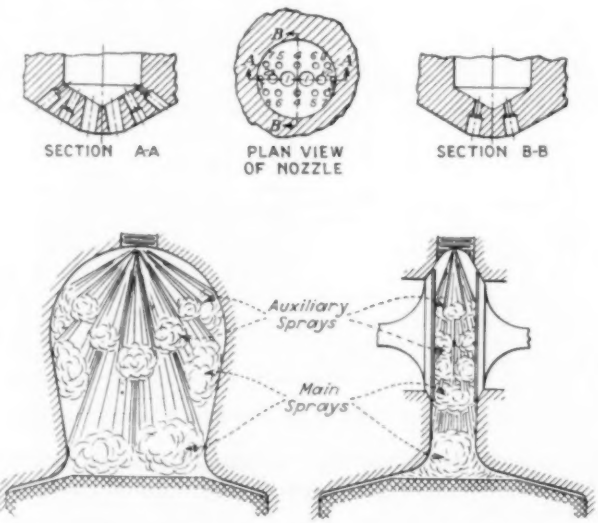

FIG. 3 PROJECTED SPRAY DISTRIBUTION, USING NOZZLE E-16

This nozzle was built as two separate nozzles, in which the orifices were drilled two at a time, and performance tests were made between the drillings. This method gave checked performance data which were desirable because of the complicated nature of the nozzles. These nozzles are denoted by the letter "E" and a number showing the number of orifices in the nozzle at the time of testing.

The performance data from the E nozzles showed rather conclusively that for this cylinder head the advantages gained by using more than six orifices were not commensurate with the complication of the nozzle. These tests determined the number of orifices to be used in future nozzles and simplified the work considerably.

During these tests the engine-operating characteristics indicated that the sprays were too close together, and about this time the results of the work on dispersion of fuel sprays at the Pennsylvania State College were published. Following the method of Dr. Schweitzer, the "boundaries of combustion" were laid out for the E-6 nozzle. Assuming this "boundary" to enclose the minimum space requirement for combustion, it was evident that the boundaries overlapped and that the sprays probably interfered with each other during combustion.

In view of these considerations it was desirable to obtain information on the effect on engine performance of the angular spacing of the fuel sprays, so another series of nozzles was designed in which the angle between the sprays was the only variation between the nozzles of the series. This series was characterized by the letter "F" and a number corresponding to the angle in degrees between sprays; thus the E-6 and the F-20 nozzles are identical nozzles. The proportional principle was not adhered to exactly for the F series, because, as the angular spacing changed, so did the volumes of air to be served by the different orifices, but the constant orifice sizes for all angles produced an average deviation small enough to seem negligible.

The results of the tests with these nozzles show very little difference between them so far as the performance curves are concerned, but observation of exhaust conditions and sensitiveness to controls led to the adoption of an angle of 25 deg. between sprays for further work with this cylinder head.

As a further check on the value of filler sprays, two 0.005-in.-diameter orifices were added in the center of nozzle F-29. This alteration brought the performance up to that of the F-26, and this improvement in performance advances the idea that the efficacy of the center jet in the C-series was in a measure, at least, due to the wide angle (30 deg.) between the main sprays.

The work thus far has shown that the number, size, and direction of the orifices in a multiple-orifice nozzle do not have critical values upon which good performance depends when used with a quiescent combustion chamber. Engine operation indicated that this combination is less sensitive to controls than an engine which uses air flow for distribution of the fuel. For example, the range of the injection advance angle from knock to miss is greater with the quiescent combustion chamber than with some test units using air flow in the combustion chamber.

SUPERCHARGING

These tests have, so far, neglected the total discharge area of the orifices in the fuel-injection valve nozzle as a definite part of the test program, but when supercharging tests were started with this cylinder head it was considered the proper time to investigate an increase in total orifice area, because with more air available for combustion it would naturally follow that more fuel should be supplied. The nozzles in this series are designated by the letter "H." The nozzles in themselves did not produce enough difference in performance to be of interest, although the oscilloscope showed that for the final H-4 nozzle the discharge orifice areas were definitely too large for the rest of the injection system and the main orifices maintained their discharge longer than the other orifices.

The significant features of these supercharging tests that can be taken from the performance curves are that the i.m.e.p. will be proportional to the weight of air available for combustion, provided that a suitable amount of fuel is distributed to this air. Therefore, from a superficial examination of performance curves (Fig. 4), supercharging merely extends the performance curves and does not essentially alter their characteristics. All this

could normally be expected, and it might seem that the tests produced nothing unusual.

However, if one looks into the conditions of engine operation, it is found that operation is considerably smoother when the engine is supercharged. The balanced-diaphragm, maximum-

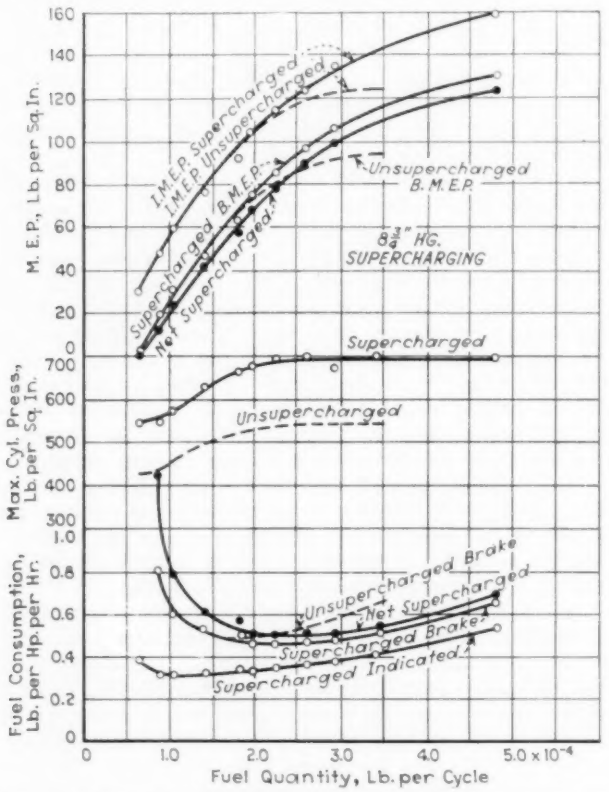

FIG. 4 COMPARATIVE PERFORMANCE CURVES, SUPERCHARGED AND UNSUPERCHARGED

cylinder-pressure indicator shows that the difference in maximum cylinder pressure between individual cycles becomes considerably less than for the unsupercharged condition, and this absence of variation of course makes the engine run smoother and allows higher injection advance angles to be used. In fact, with 9 in. of mercury supercharging pressure it was possible to peak over the power curve by advancing the injection until approximately a 10 per cent drop in power was recorded. This curve, as shown in Fig. 5, is quite flat, and in combination with the maximum-cylinder-pressure curve shows that the power gained by advancing injection beyond a certain point is too expensive in added stress on the engine parts.

This ability to peak over the power curve was not entirely due to the supercharging, but was in a measure due to the construction of the nozzle, which did not entirely conform to the specifications of any of the series mentioned, and will therefore be designated as nozzle X. For comparison, the performance of a nozzle with more nearly proportional orifices is shown, and these curves are parallel to the others, except the maximum-cylinder-pressure curve. The difference in these pressure curves indicates that higher rates of pressure rise may be achieved with homogeneous mixture of fuel and air and that an unbalanced mixture has a suppressing influence on both the rate of pressure rise and the maximum pressure attained.

The term homogeneous is used only in a comparative sense, as a study of dispersion data will show the futility of trying to obtain a truly homogeneous mixture when injecting fuel through a round-hole orifice nozzle into a quiescent combustion chamber. This improbability is reflected in specific fuel consumption values. As the time of injection was advanced the engine performance conditions diverged from those of the true quiescent combustion chamber because of the injection of an increasing amount of fuel into the air that still had some forced flow due to the motion of the piston.

From this work it appears that the quiescent combustion chamber in conjunction with a multiple round-hole orifice nozzle has inherent limitations that may prevent it from attaining the high performance which is ultimately expected of the compression-ignition, fuel-injection engine. But on the other hand it makes for a consistent engine and one which is not particularly critical, so that the combustion phenomena proceed in an orderly manner, and therefore these phenomena

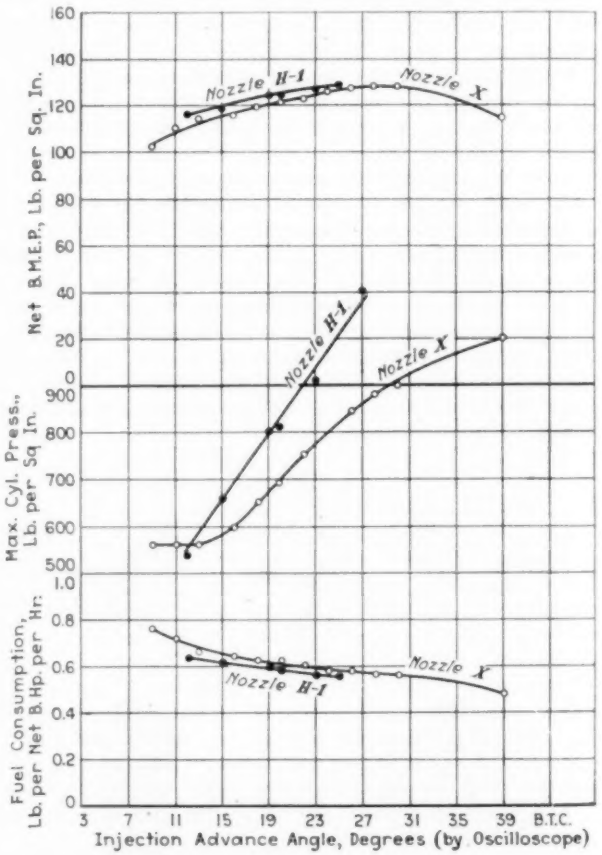

FIG. 5 COMPARISON OF PERFORMANCE WITH NOZZLES X AND H-1

can probably be studied and experimented upon to better advantage than in the more complicated forms of combustion chambers with air flow.

DOUBLE-STEM FUEL-INJECTION VALVE

One objection to the use of round-hole orifices for the injection of fuel is that the area is rigidly fixed, and within the range of pressures between valve-opening pressure and the maximum injection pressure, it is difficult to obtain much variation in the rate of discharge. For those who desire to control the rate of combustion by the rate of discharge this is a very definite handicap. An attempt was made with this engine to design a cam which would inject fuel at a theoretical rate determined from an ideal indicator card, taking into account the compressibility of the fuel, injection lag, and ignition lag. The results ob-

tained did not indicate that ideal combustion was taking place in the cylinder, so the problem was attacked from a different angle.

To produce a fuel-injection valve that would be more adaptable, the different means for varying the discharge area were investigated, and this resulted in the adoption of a multiple-orifice nozzle in combination with a fuel-injection valve in which two concentric stems uncovered two sets of orifices at different pressures in the injection system. The fuel-injection valve incorporating this feature is shown in Fig. 6, and although it is complicated in construction, it functioned satisfactorily. The only mechanical inconvenience with this valve was the necessity for lapping the flat seats occasionally to remove erosion marks, but this was by no means excessive.

The first nozzle D-1 tested with this double-stem valve had no homolog among the single-stem valve nozzles, and its performance was disappointing. To determine the cause of this decrease in performance a nozzle D-2 was designed homologous

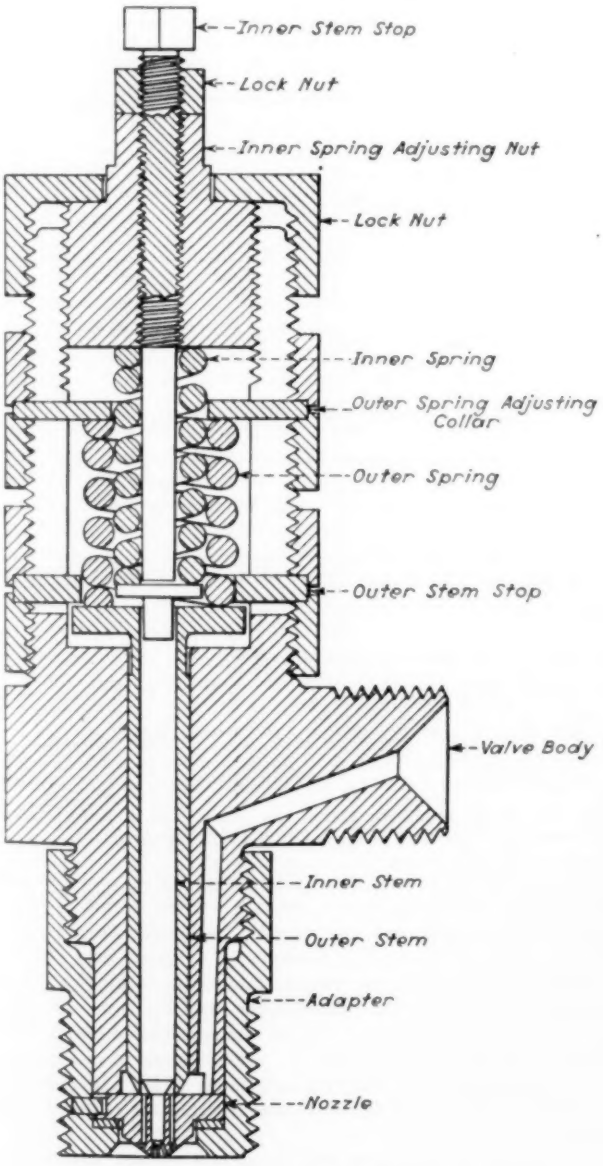

Fig. 6 Double-Stem Valve

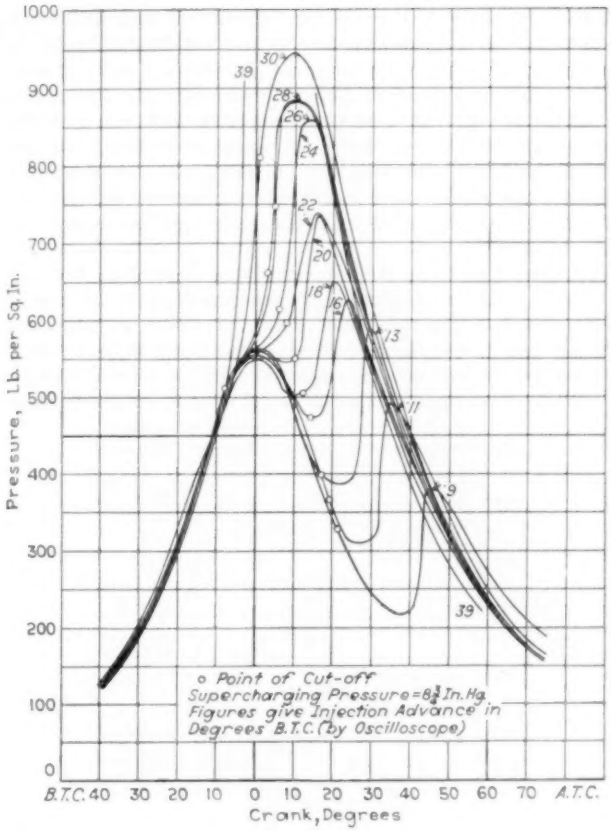

Fig. 7 Effect of Injection Advance on the Pressure Time Card

to No. 9 nozzle of the first single-stem series. This D-2 nozzle also incorporates the idea of placing the primary injection in the relatively cold outer portion of the combustion-chamber disk, and thereby should give an opportunity for determining whether there is any advantage to be gained by trying to preheat cooler sections. It is possible that these sprays in close proximity to cooled walls did not accomplish this purpose, but in the absence of proof as to whether the sprays heated the section or whether the section had a quenching action on the sprays it will be considered that this section did get some preliminary heating.

The opposite effect was obtained with the D-3 nozzle (homolog E-8) by directing the primary sprays down the central axis of the combustion chamber to create a super-hot spot between the valve heads through which the main sprays had to pass when the main injection was started.

Indicator cards were taken and injection rates determined with a receiver mounted on the flywheel of the engine. A coordination of these data with the usual performance data shows that the pressures in the engine cylinder can be controlled within limits by the rates of injection obtained with a double-stem valve, but the effect on the combustion process is usually deleterious, and the resulting m.e.p. is not so good as with the corresponding single-stem valve. One striking feature of the data is the apparently constant time interval of 0.0033 sec. between the first introduction of fuel and the start of pressure rise due to combustion.

Indicator Cards

This discussion has thus far considered only such information as may be gained through comparatively direct measurement

of the quantities involved. The analysis of indicator cards furnishes information which may not be as exact quantitatively as the usual performance data, but is none the less valuable in showing trends and tendencies which can be determined in no other way. An analysis of indicator cards taken during these engine tests not only checks many conclusions from the engine data, but also supplements them with additional information as to the manner in which the benefits indicated as possible by theoretical calculations may best be realized in actual engine practice.

The most interesting series of cards were those taken with the X nozzle in the single-stem valve corresponding to the engine performance in Fig. 5. These cards, as shown in combined form in Fig. 7, were taken with all engine controls in the same setting except for the variation of injection advance angle. They differ from the engine conditions of the unsupercharged tests

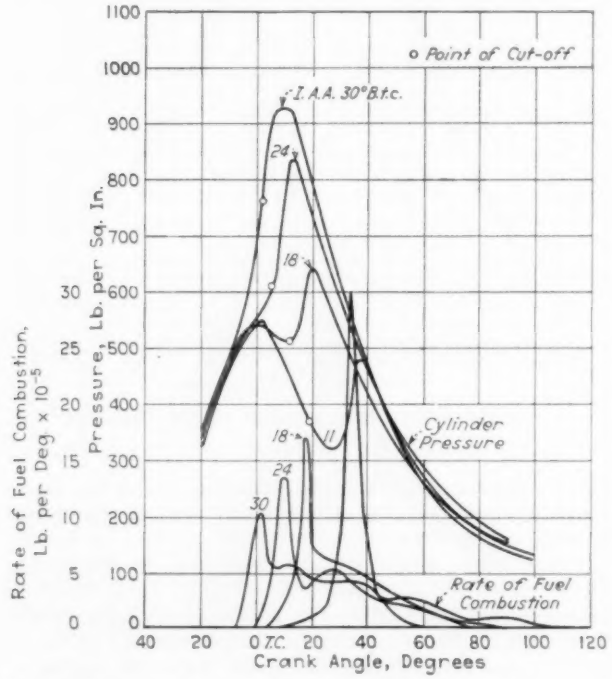

FIG. 8 CHANGE IN RATE OF COMBUSTION WITH ADVANCE OF INJECTION

in that the inlet air pressure is 8.75 in. Hg instead of atmospheric, and the inlet air temperature is 125 deg. fahr. instead of 96 deg. fahr. The pressure curves are differentiated by giving for each curve the apparent start of injection as determined with the oscilloscope when injecting into the atmosphere. The reference point shown by the circle on the pressure curve is the point at which the start of cut-off at the fuel pump affects the rate of injection. This point can be determined more definitely than the start of injection, so it was used as a reference point for determining time lags. The method devised by Schweitzer was used for the analysis of the indicator cards. The curves of rate of combustion in Fig. 8 show that the combustion process changes with injection advance angle and checks the observation of engine performance characteristics in that several knock ranges are passed through with the attendant change in rate of pressure rise.

Another point that is forcibly demonstrated is the importance of the start of ignition for smooth operation, and this, in turn, indicates that perhaps the supercharger air pressure is not responsible for the smooth operation during the supercharging tests, but that probably the increased temperature of the air was more responsible. To supplement this reasoning the calculated temperatures at the end of compression are shown in Fig. 9 for the usual range of initial pressure and temperature and of compression ratios.

The curve of rate of combustion in the case of the double-stem valve shows a remarkable tendency to follow the rate of injection for the first part of the curve, but in no case is the

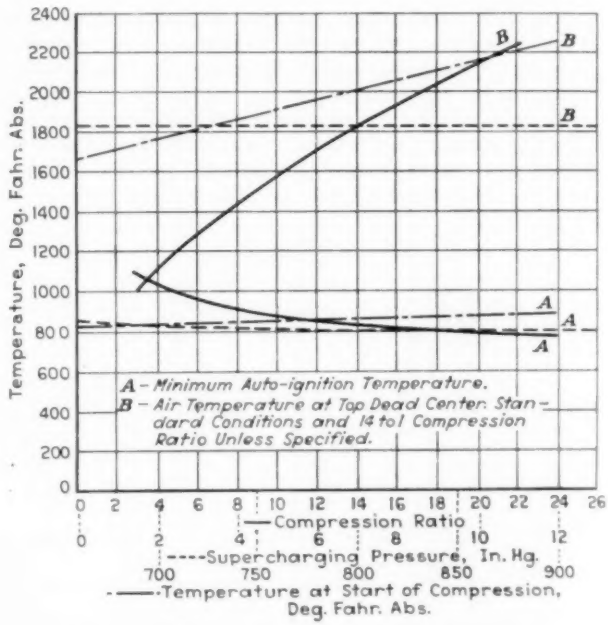

FIG. 9 TEMPERATURES AT END OF COMPRESSION

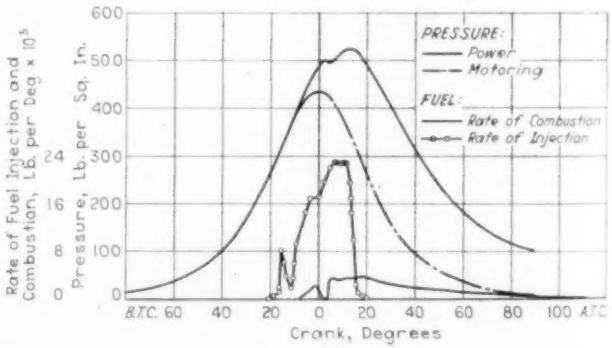

FIG. 10 PRESSURE TIME CARD AND RATES OF INJECTION AND COMBUSTION WITH DOUBLE-STEM VALVE

maximum as great as with a single-stem valve, and the last part of the combustion curve shows a lengthy period of afterburning which was indicated during the engine tests by red flame and black smoke in the exhaust. A typical rate of combustion curve for a double-stem card is shown in Fig. 10. It is possible that the higher temperatures resulting from the combustion of the primary fuel reduced the penetration of the main injection to such an extent that the whole scheme of distribution was disarranged with resulting rich zones which had difficulty in finding sufficient air for combustion within the required time limit.

A number of improvements in method suggest themselves, and further work with the double-stem injection valve may be

done at some future time, but at present it is thought that other simpler means of improving performance offer better opportunities and that perhaps a better understanding of the combustion process with the single-stem valve would be of considerable value in outlining any future programs for the double-stem valve.

The indicator cards presented here were not taken for the purpose of analysis, but were taken along with the performance tests mainly for a check on the pressures involved, and it is hoped that indicator cards taken in the course of a program intended for the sole purpose of studying the combustion process will yield information that will be of even more value for specific applications. This consideration brings up the question of comparison of data from different test units and the application of results obtained from one engine to another similar engine. The results obtained in this work are comparable and consistent within themselves, and the general effects noted during the performance tests will obtain in all quiescent combustion chambers to a greater or less degree.

The two great factors in obtaining improved performance for a compression-ignition fuel-injection engine are of course the control of distribution and control of combustion. For the distribution of the fuel to the air in the quiescent combustion chamber by means of multiple-orifice injection nozzles, these tests give a principle which may be followed in the design of the nozzles and show some of the difficulties encountered. For the control of combustion these tests give indications of the possibilities for control of rate of pressure rise through the control of rate of combustion and show that the rate of fuel injection is not particularly important in influencing the rate of combustion, and therefore the rate of pressure rise for high-speed operation.

This discussion has neglected entirely the effect of various factors on the physical parts of the engine, because in more than 800 hours of engine operation included in these tests there have been no failures or replacements due to the conditions of operation imposed upon the mechanism. Maximum cylinder pressures have usually been less than 800 lb. per sq. in., but in the supercharging tests the pressures encountered were slightly over 1000 lb. per sq. in. without mechanical troubles, so it is believed that an engine with a quiescent combustion chamber is entirely practicable for continued consistent performance.

Bibliography

The test work outlined in this paper is reported in detail in the following publications which give the necessary collateral references:

Discussion

C. L. Cummins.[2] The writer's experience in developing a high-speed Diesel engine confirms the author's conclusion that the quiescent combustion chamber is a consistent performer. The combustion chamber of the Cummins engine is not strictly a quiescent one, although it may be considered quiescent so far as the distribution of the main part of the fuel charge is concerned. Air flow is used only for a particular purpose directly under the fuel-injection valve, and the percentage of air involved is small.

The author has neglected to say much about spray penetrations, which are of considerable interest to the engine designer when laying out similar combustion chambers for different sizes of engine. These penetrations are especially important with our injection system, which gives a better atomized and more widely dispersed spray than it is possible to obtain with "solid injection" through a round-hole orifice.

The use of air flow in combustion chambers appears to have some interesting possibilities, but there is almost a complete lack of reliable information upon which to base the utilization of air flow. Experience has shown some of the advantages to be gained, but there have always been accompanying disadvantages which have kept us from using air flow as a means for distributing fuel in a combustion chamber.

Author's Closure

Mr. Cummins is quite right in pointing out that spray penetrations have been neglected, but as this work was done with only minor changes in the combustion chamber shape or dimensions, the question of spray penetration was considered of less importance than the factors which had been investigated at the time the paper was prepared.

In connection with Mr. Cummins' observations on combustion chambers with air flow, at the present time the author quite agrees with him in general, but wants to make it clear that, although this paper deals entirely with the quiescent combustion chamber, the work has not been abandoned on combustion chambers with air flow. It is hoped that further research may discover methods for making the benefits of air flow available without incurring prohibitive penalties.

PME-53-1

Lubrication of Textile Machinery

By L. A. BAUDOIN,[1] NEW YORK, N. Y.

Cotton textiles require absolute cleanliness during manufacture and finishing, and all operations including the lubrication of the equipment are secondary to this requirement. Present designs incorporate modern developments which aid lubrication, and also provide a reserve supply of lubricant with ample protection to the fabric. Frequent application of minimum quantities of lubricant is accepted practice, but "freak" oils are not necessary. A list is included which indicates the frequency of application, cleaning period, and the product required.

LUBRICATION of textile machinery resolves itself to the consideration of groups of machines, each absolutely essential to the finished product, but performing their several duties as independent operations on the fiber, yarn, or cloth. To avoid complications, only cotton textiles are considered in this paper, for the reason that linen, woolen, carpet (combination cotton and wool), jute, silk, rayon, and knit goods each require independent handling from a manufacturing standpoint, and each process differs from the other and all from cotton. There are many similar features, many machines have a close resemblance, but the staple of wool varies from several inches to a foot or more, and silk and rayon are continuous.

Linen has characteristics that are not found in either, and knitting machines differ materially from any cloth-making equipment.

The care of textile machinery is one of the lessons that must be learned by actual experience with the equipment. The care includes lubrication, because the performance required of the intricate machines used in the textile industry can be attained only when friction has been reduced to a minimum. It is well known that this is not an actual achievement, and this paper points out a few of the numerous handicaps.

In the first place, many textile mills, long established, are using machinery designed and built some years before lubrication arrived at the stage of perfection forced by the demands of automotive equipment, and the fact that mill owners have not changed their machinery as rapidly as new developments along lubrication lines were advanced is not a reflection upon them at all, for the reason that in many instances such a move would require the scrapping of thousands of machines which are otherwise suitable for use.

In many instances where a small number of large capacity machines could be replaced to advantage it has been done, and the lubrication features of these new machines are in line with the very best practice today. For instance ball and roller bearings are replacing plain babbitted journals on fan shafts and all load-carrying bearings. Gear sets are well protected from dust and lint and so arranged that the cut gears run in a bath of oil, and in cases where first cost prohibits redesign to incorporate roller bearings, the ones provided are equipped with pressure-gun fittings and reservoirs for grease and provision to shield the bearing from the work so that the lubricant does not come in contact with the cotton fibers.

Throughout the cotton-manufacturing industry lubrication has been a secondary consideration, being forced into the near background by the absolute necessity of keeping oil and grease from spotting the goods. This care starts at the bale breaker and is vigilantly maintained until the cloth is shipped from the finishing plant.

Hand oiling of intricate machine parts requires a conscientiousness bordering on the superhuman to insure that each and every bearing and stud requiring it has an ample oil film. In this case experience alone is no safeguard, and when once passed by, the bearing, stud, or oil hole is soon passed again, and worst of all, the corresponding location on every similar machine is soon absolutely forgotten and neglected until excessive wear causes misalignment or actual breakage, contributing to lowered production. The seriousness of this condition is plainly shown by the accompanying illustrations which show worn parts picked at random. These parts may be readily identified.

Textile mills must have hundreds and in some cases thousands of certain machines, and one manufacturer regrets that the price at which the machines are sold does not allow equipping them with devices for holding an ample supply of oil and regulating its flow to the working parts. Oil holes and open bearings make up the oiling system on these machines. But the sky is clearing, because another manufacturer is now experimenting with one-shot oiling, and has built two large machines equipped with this system.

Passing from the spinning and weaving departments to enter that of cloth finishing, most of the lint and dust is left behind, and many of the machines are equipped with roller bearings or pressure-gun fittings and recesses for excess lubricant. Where gear sets are required they are well protected and contain ample lubricant. However, some of the cloth-handling machines are retained with their characteristic plain bearings.

Cleanliness is an absolute necessity and frequent cleaning periods have always been in order. Lint and waste allowed to accumulate on or near bearings and wearing surfaces cause endless trouble from wear because of the sand and grit present; so all machines, from bale breakers to cards, are brushed daily and thoroughly cleaned each week. At one mill the cans supplying the slivers are all allowed to run out together, and before full cans are replaced the back of the machine is thoroughly cleaned. The fronts of the slivers are cleaned every day.

The grit getting into the bearings wears them out rapidly, but the lint and fly which adhere to the outside of bearings and adjacent parts absorb oil readily and actually dry out the bearing by capillary action.

Mill owners and agents naturally consider cost of production. Operators and machine designers consider lightening the opera-

[1] Assistant Supervising Engineer, Sinclair Refining Co. For eight years Mr. Baudoin was connected with various plants as assistant engineer and in 1910 became master mechanic for the Edwards and Loomis Co., Chicago, Ill. While with that company he developed several new material-handling and labor-saving systems for increasing production. He joined the Sinclair Refining Co. as lubrication engineer in 1919.

Contributed by the Lubrication Engineering Sub-Committee of the Petroleum Division and presented at the Textile Sessions of the Annual Meeting, New York, N. Y., Dec. 1 to 5, 1930, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

TABLE 1 TEXTILE MACHINERY WITH FREQUENCY OF LUBRICATING AND CLEANING

Equipment	Lubricating frequency	Cleaning periods	Product No.	Remarks
Bale breakers, plain bearings	Every 2 days	Each week	1	
Lattice feed table, plain bearings	Every 2 days		1	
Openers:				
Reserve box automatic feeders:				
Plain bearings	Every day		1	
Ball bearings	Every 6 mo.		8	
Creighton vertical opener:				
Plain bearings	Every day	Each week	1	
Step bearing	Every day		1	The step bearing of this machine is surrounded by water jacket which must be kept filled
Vertical openers, ball bearings	Every 6 mo.	Each week	8	Provided with pressure-gun fittings
Beater type, ball bearings	Every 6 mo.	Each week	8	
Condensers, oil tubes to bearings	Every day		1	
Exhaust fans, ring-oiled bearings	Every month		1	
Distributing conveyors, plain bearings	Every day	Clean boxes every day	1	Gears are well protected from dirt
Gear boxes	Every month		1	
Combination opener:				
Breaker picker	Twice a day	Every 6 mo.	1	
Fan bearings (roller)	Every 6 mo.		8	
Breaker lapper, plain bearings	Every day	Every 6 mo.	1	
Beater roller bearings	Every 6 mo.		8	
Evener cones roller bearings	Every 6 mo.		8	
Lap racks roller bearings	Every 6 mo.		8	
Finishing picker	Twice a day	Every 6 mo.	1	Draft begins
Lapping picker, plain bearings	Every day	Every 6 mo.	1	
Roller bearings	Every 6 mo.		8	
Waste pickers:				
Willow, roller bearings	Every 6 mo.	Every 6 mo.	8	
Plain bearings	Every day		1	
Card and picker waste cleaners	Every day	Every 6 mo.	1	
Roller bearings	Every 6 mo.		8	
Roving and hard waste cleaners	Every day	Every 6 mo.	1	
Carding machines, cylinders	Every day	Every day	1	These bearings and many others are kept filled with grease for safety, oil is used as well every day
Licker-ins	Every week	Every day	1	
Doffers	Every week	Every day	1	
Slow moving parts, bearings and gears	Every day	Every day	1	
Comb boxes	Every week		2	
Sliver, front and back rolls	Every day	As cans run empty clean back of machine	2	
Top rolls, gears	Every day	Fronts each day	1	
Ribbon laps, plain bearings	Every day		1	
If roller bearings	Every 6 mo.		8	
Combers, cylinder shafts	Every day	Twice a year	1	Many plain bearings of this machine are provided with waste pocket to retain supply of oil
Head end gears and cams	Every day		1	
Fan, plain bearings	Every week		8	
Roller bearings	Every 6 mo.		8	
Steel rolls	Every day		1	
Detaching rolls	Once a week		3	These rolls have removable bushings and oil is applied by hand after the bushings are removed; see text
Guide arms	Twice a week		1	
Drawing frames:				
Fast parts and driving gears	Every day	Steel rolls scoured 1 mo.	1	
Lower rolls	Every week	Leather rolls each week	8	
Top rolls	Every day	Clearer washed each hour	1	
Head and foot end gears	Every day		1	
Newer equipment: roller bearings	Every 6 mo.		8	
Slubbers				
Speeders				
1st intermediates				
2d intermediates				
Jack frames				
Fine moving frames				
Bobbing gears and spindles	Every doff		1	
Spindle wells	Every month		5	
Plain bearings and gears	Every day		1	
Bolsters	Every week		1	
Front rolls	Every day	Every week	1	
Middle and back rolls	Every week[1]			
Top rolls	Every week		1	
Bottom rolls, wind back and builder gears	Every 2 wks.		1	
Differential motion	At cleaning period	Every 6 mo.	1	
Spinning:				
Mules:		Inspection once per year		
Spindles	Twice a day		4	
Overhead drives	Every day		1	
Live head, back head	Every day		1	
Cylinder bearings, stud rollers	Every day		1	
Back shaft, fallers	Every day		1	
Carriage wheels, band pulleys—leather rolls	Every day		1	
Ring spinners:				
Spindles, old type	Every 2 wks.		4	
Spindles, new type	Once a month		4	
Cylinder shafts, old	Twice a week		1	
Cylinder shafts, new (ring)	Once a month		1	
Roller bearing	Every 6 months		8	
Head gears, old	Once a week		8	
Head gears, new	Worm runs in bath		1	
Front steel roll	Every day		1	
Back steel roll	Every week		1	
Top and middle rolls	Twice a week		1	
Twisters, spindles, old	Each week		5	Run wet
Spindles, new	Each month		5	
Cylinder and roll bearings	Every 2 days		1	
Rings	Every doff		9	
Head gears, studs	Every day		1	
Fancy twisters, same as above except that they run without water				
Spoolers, spindles, old	Once a week		1	
Spindles, new	Once a month		1	
Cylinder shaft	Once a week		1	
Winders, drive shaft	Once a month		8	
Cam winding motion	Once a month		1	
Universal winders	Once a week		1	Run in oil bath well protected from lint
Reeler, shaft bearings	3 times week		1	
Traverse motion	3 times week		1	
Swing-gate bearing	Once a month		8	
Warper, cylinder	Every week		1	
Beam arbors	Every day		1	
(When roller bearings)	Every 6 mo.		8	
Balling attachment	Every day		1	
Floor stand	Every day		1	
Quilling machines:				
Spindles	Every month		4	
Cylinder shaft, studs, gears	Every day		1	
Universal filling winder shaft	Every week		1	
Cam winding motion	Every week		1	
Slasher cylinder bearings	3 times week		6	Steam rolls
Balance of machine	3 times week		1	
Weaving:[2]				

[1] When front rolls are cleaned.

TABLE 1 TEXTILE MACHINERY WITH FREQUENCY OF LUBRICATING AND CLEANING *(Continued)*

Equipment	Lubricating frequency	Cleaning periods	Product No.	Remarks
Pick cams and balls				
Pick shaft bearings; crank arms; crank-shaft bearings; rocker shaft boxes	Every day		1	
Cam-shaft bearings, auxiliary shaft boxes; harness cams; idle gear stud; treadle roll pins; filling cams and followers; protector-rod bearings; friction-pulley parts	Every 2 days		1	
Treadles; shuttle feeler bushing; oscillator cam follower; transferer; other shuttle and knock-off parts	Every 3 days		1	
Loose pulley and shipper; lay guides; fork slides; starting-rod bearings; take-up parts; spring shaft; let-off parts; beam and whip roll bearings; harness roll bearings; Lacy top; parallel stud and spring; bobbin disc; pawls and support	Once a week		1	
Cut gears; parallel tongue; temple thread cutter; temple bar; cutter spring and stud; shuttle feeler cam path	Once a week		8	
Occasionally grease bemble	Once a week		8	Very small quantity required
Drop of oil to filling motion shipper bushing	Once a week		1	
L. O. internal gear and pinion, and path of nub of controlling lever link	Once a week		8	
Jacquard attachments	Once a week		1	
Brushers (horizontal and vertical), fast-moving parts	Every day		1	
Slow-moving parts	Every week		1	
Inspection machines	Every day		1	
Folders	Every day		1	
Presses (screw)	Every week		1	
Cloth-finishing machinery				
Singers, plain bearings	Twice a day		1	
Roller bearings	Every 6 mo.		8	
Washing; shafting	Once a week		1	
Bleaching:				
Kier—piling mach. gear box	Every 2 wks.		8	
Squeezers: large bearings	As needed		10	
Other bearings	Once a day		1	
Drier, pressure gun fittings	Once a week		8	
Plain bearings	Once a week		8	
Winders	Twice a day		1	
Shearing machines: plain bearings	Twice a day		1	
Roller bearings	Every 6 mo.		8	
Shear knives (edges)	Twice a day		7	Saturated felt
Float thread shearing machine	Twice a day		1	If pressure fittings provided use grease no. 8
Loop cutters	Twice per day		1	
Unrolling frames	Every day		1	
Railway sewing machines	Every day		4	
Spreader rolls	Every day		1	
Mercerizing frames, wash box	No oil used			
Traveling chain	Caustic soda acts as lubricant			
Diastoforing: frames	3 times day		1	
Scourers	Twice a wk.		10[a]	
Dyeing: jig	Once a week		8	
Roper	Once a week		8	
Drier (pressure fittings)	Once a week		8	
Slop padders	Once a week		8	
Indigo dyeing rolls	Every day		1	
Shafting	Every day		1	
Printing machines: cylinder bearings	Every day		6	
Offset rolls	Every week		10[a]	
Inking rolls, etc.	Every day		1	
Dry cams	Every day		6	
Steamers (pressure fittings)	Once a week		8	
Ager (pressure fittings)	Once a week		8	
Soapers: ropers	Once a week		8	
Soapers: open	Once a week		8	
Stretcher drier, pressure fittings	Each week		8	
Tenter frames: drive ends (sight feed cups)			1	
Traveling chains	3 times week		1	
Gears	Every week		8	
Calenders, main rolls	Twice a week		10[a]	Steam.

[a] This hard grease may be obtained in block form and applied to the bearings on a perforated metal plate previously fitted to the bearing. The journal heat allows sufficient feed from grease cake through the perforations. Grease should be selected which will not char or plug up perforations.

tion, convenience of handling, cleanliness, and adaption to high speed when any new equipment is contemplated. Lubrication is still secondary and must give way completely to cleanliness.

Lubricant manufacturers must work out the problem with existing equipment, but are insisting that, where necessary, future designs incorporate provision for an adequate supply of the proper oil to suit that particular condition.

Cleanliness is paramount, and so freak oils have found their way into the textile industry to the extent that one of the prime requisites is that it *does not flow* at room temperature. An-

other condition of combination high pressure and hot bearing is met by removing the bearing cap entirely and replacing it with a piece of leaf tallow or suet. That serious trouble has not occurred is simply that the journal speed is slow.

The oils actually required for textile-mill lubrication are comparatively few in number, their characteristics and particular conditions of service being as shown in Table 2.

High-grade straight mineral oils should be chosen where possible for textile-mill service, because when well refined their characteristics do not change in service. They do not tend to form gummy residues nor become rancid. In some special cases such as wet twisters, water-resisting compounds are neces-

sary, and in the case of shearers where the knives run steel to steel a special compound is necessary. Calenders, dry cans, and printing machines running at high temperature and high bearing pressures require a filtered oil of high viscosity. Other bearings subject to high pressure, but slow speed, require a special heavy grease that will feed slowly and not carbonize under the temperature or dry out in service.

The list of textile machinery (Table 1) for manufacturing and finishing cotton cloth is given for completeness. The key numbers given with the lubricant indicate the particular grade to use. The application period is given as a guide only, but conforms to actual experience in large plants manufacturing and finishing cotton cloth. The periods shown for looms were copied verbatim from one manufacturer's bulletin.

The author wishes to thank Messrs. F. K. Hendrickson and S. H. Hillard, of Whiting Machine Company; W. H. Chase, Draper Corp.; L. A. Latham, Crompton & Knowles Loom Works; E. H. Marble, Curtis and Marble Company; C. F. Broughton and W. O. Buzzell, Wamsutta Mills; and Arthur Hirsh, American Print Mills, for their kind cooperation and aid in offering details for this paper.

Discussion

D. V. WATERS.[2] The writer has had no experience with the lubrication of textile machinery. It would seem, however, that

[2] Machine Design Division, Western Electric Co., Chicago, Ill. Mem. A.S.M.E.

experience gained with machinery which insulates wire with cotton or silk could be, to some extent, applied.

The author has mentioned certain places on machinery difficult to lubricate because any excess or leakage of lubricant is detrimental to the product. If loads and speeds are not too high, it is perfectly feasible to use anti-friction bearings made from one of the stainless steels. Such bearings are packed with light grease at assembly and thoroughly sealed against the entrance of foreign matter, after which they are run indefinitely with no attention whatsoever. We have found that these bearings give no trouble during the period between machine overhauls. It is believed that the use of such constructions will, in many cases, eliminate many of the problems connected with getting oil into bearings and its retention thereafter.

Where lubrication facilities must be provided, wick-feed oil systems appear to possess certain advantages, as the oil is filtered by its passage through the wick and a uniform and not too copious amount of oil is fed. Careful proportioning of the length and diameter of wicks, oil-level height, etc., is required in any satisfactory wick-feed oil system.

The company with which the writer is connected has conducted laboratory tests of various commercial feeding systems. These tests have indicated that such systems work best with oils coming within relatively narrow range of viscosities.

C. H. Ramsey.[3] To that portion of the paper having to do with the lubrication of old-fashioned sleeve-type bearings, stud-supported idle gears, sprockets, etc., illustrations of which have been submitted, no reference is made other than to commend the suggestions therein contained.

Earnest emphasis of the development of anti-friction bearings, however, is believed to be very appropriate. There is a constantly increasing and more insistent demand for ball and roller bearing equipped textile machinery, not only because of its contribution to the diminution of power consumption, but also because they lend themselves so admirably to complete enclosures, with ample capacity within the enclosures for lubricant reservoirs.

Complete enclosures for gearing of all types is also being more and more resorted to, not only because of the safety factor, but also because of the cleanliness, protection of the gearing from dirt, grit, etc., and also because the enclosures provide lubricant reservoirs tending toward a more quiet action of the gears and materially preserving their wearing qualities.

The writer thinks that two very important natural forces often used in the machinery field and yet again too often neglected are the action of centrifugal force and the force of gravity. They are utterly and always dependable and have wide possibilities of application in the field of lubrication.

A notable example of this will be found in the writer's patent (1,778,432, October 14, 1930, entitled "Lubricating System"). We have made practical application of this patent in our speed-reducing transmission, and it has worked out in full accord with our expectations. In this example, a disk is mounted on the highest speed shaft, which penetrates the box, which, in action, distributes the lubricant over the entire interior of enclosure, deluging the surface of the enclosure, the action of gravity of course causing it to drain back into the common reservoir in which the disk dips and, in passing, it percolates through all the bearings and gearing, lubricating them thoroughly.

Another familiar detail of textile machinery is the friction-plate method of securing variable speed, which still finds a wide range of usefulness and, indeed, is very efficient and dependable if properly designed and strategically mounted. Years of experience have quite conclusively demonstrated the most useful and dependable type of thrust bearing (to keep the friction disk in contact with the friction wheel) to be two steel pins of glass hardness running against each other. The one objection to this has been the difficulty of keeping them properly lubricated, the heat generated being so great at times as to draw the temper from the steel points and, hence, ruining them. This difficulty has been entirely obviated by enclosing these two points within a housing and constructing in the upper portion of the housing a suitably designed funnel, the lower aperture of which is trained to drip the contents of the funnel on the contacting points of the steel thrust bearing. A disk dipping in the lubricant, the lower half of the enclosure forming a suitable reservoir therefor, deluges the complete interior of the housing with lubricant all the while the machine is in motion. A generous supply of this deluge finds its way into the funnel, providing a continual stream of lubricant for the thrust bearing all the while the machine is in motion. This has worked out admirably in practice. We have made applications of it and have made application for patent thereon.

It is of course obvious that the use of gravity and centrifugal force in the distribution of lubricant entails the use of fluid oil. Experience has indicated to us that fluid oil is superior if it can be properly confined within its enclosures, so as to preclude the possibility of discharge, so that fabric being handled on textile machines, may be kept immaculate.

M. A. Golrick, Jr.[4] The subject of lubrication is generally accepted with a nod of the head and then dismissed from the conscious mind until forcibly reminded by the failure or more often the lack of lubrication at some point. If the subject were of a controversial nature, it would be constantly in mind and freely discussed. It is the lassitude of every one who should be vitally interested that makes lubrication a secondary instead of a primary issue.

The author mentions the difficulties of old machines and the attention required to lubricate by hand these old machines. However, it is believed he could emphasize this condition as many plants continue to use machines which were designed for heavy duty and long life. Due to their inherent designs, these machines are the "perpetual or everlasting type," which seem to live forever, yet are a constant source of trouble. In most cases this is due to the increasing increments of speed which are added one after another. It seems impossible to run many of these machines indefinitely, yet this is apparently the policy that is maintained for many reasons. In most cases the reason is that the cost of new machines is too much for an industry which has labored so long under financial stringency. On the other hand, the constant demand for increased speed does not allow a stable lubrication condition to be maintained.

The schedule presented on frequency of lubrication and cleaning is worthy of special attention, for this forms the basis of an admirable schedule, though the writer would caution against its adoption in whole without careful consideration. In one finishing plant, which had considerable machinery of the type requiring constant lubrication attention, a complete lubrication chart had to be made for each machine. The chart was in minute detail for each machine and showed the total number of points to be lubricated, so that new employees and also old employees would be well informed as to each machine's requirements. In passing, it might be well to mention that a 100 per cent factor of safety was used to set the frequency period, and this proved to be an ample safeguard. This schedule was an absolute necessity in this case, as repeated failures due to lack of lubrication were not corrected until the schedule was adopted.

Now, machinery is generally well designed to require only a

[3] President, Morrison Machine Company, Paterson, N. J. Mem. A.S.M.E.

[4] Dutchess Bleachery, Inc., Wappingers Falls, N. Y.

minimum of attention from the operator, and the author has covered this phase well. His statement that manufacturers must design to meet lubrication requirements is one that is being accepted by most designers. The subject must be constantly kept to the fore by lubricating engineers as their special duty toward industry.

SAMUEL CABOT.[5] To be effective, a lubricant must interpose a smooth, mobile film between the two moving surfaces, thus keeping them apart. Lubricants of high viscosity are required where the film has to withstand great pressures between the moving surfaces. For light-weight parts, low viscosity lubricants are preferred because high viscosity means increased internal friction or friction between the molecules of the lubricant.

An ideal lubricant is one which would have the quality found in high-viscosity liquids of resisting the squeezing-out action caused by the pressure of one bearing on another bearing, and would at the same time have the low internal friction found in liquids of which the molecules are small and thus have low viscosity.

Certain products called colloids which may be introduced into lubricants are attracted by the metal surfaces of the bearings. They are adsorbed to each of the bearings quite strongly in a thin film, said to be the thickness of one molecule. Attached, but less strongly on this film, is a more loosely grouped layer of these, much like minnows around a dead clam. These large molecules are not actually dissolved in the lubricating liquid, but in colloidal solution in it. They are in constant motion and can be seen swarming under an ultra-microscope. When they come close to the metal surface, they are attracted to it, become adsorbed to it, and lose their motion, concentrating largely near the metal surfaces.

These colloids impart to the lubricant some of the ideal qualities of high viscosity and low internal friction. The reason for this is that colloids being on the metal surface and adsorbed by it are very difficult to squeeze out, and as they have a strong affinity for the lubricant, they prevent it from being squeezed out. Thus a lubricant of somewhat lower viscosity may be advantageously used where high viscosities have been the rule. They also tend to smooth any microscopic roughness on the metal bearing surface.

The qualities the writer has been trying to describe may be briefly termed "oiliness or slip." It is what a small amount of the colloid, called soap, gives to water, or mud gives to an asphalt road. The best colloids to use with lubricating oil are those which are most closely related to the oil: They are called iso-colloids, which means that they are of the same family as the liquid they are in. From 5 to 20 per cent of a colloid of this kind added to a lubricant will make it more slippery, less likely to squeeze out of a lower cold test, and will maintain a lubricating film longer after oil feed has been shut off.

PME-53-2

New Pipe-Still Design

By LUIS DE FLOREZ,[1] NEW YORK, N. Y.

Methods and apparatus for applying heat to oil constitute the essential features of modern refinery practice. The tabular oil heater has developed rapidly since adequate turbulence can be obtained in the tubes by high velocity and the surface can be arranged to give comparatively even distribution of heat.

The author describes a new design of still which does away with the conventional brick-lined combustion space and permits absorption of heat to begin immediately after its generation. This has led to an arrangement of heating surface where the flame from the burner is exposed directly to what may be considered as an excess of heating surface. With this arrangement the flame heats the tubes by radiance, and the tubes cool the flame.

USE of the tubular oil heater in refining has increased rapidly in recent years. In its simplest form it consists of a box-like furnace containing a pipe coil through which the oil is pumped continuously, and heated directly by gas or oil burners located in the lower part of the structure. A study of the heat distribution shows that the bulk of the work of the heater is actually accomplished by the comparatively small section of coil at the fire. Under these circumstances, it is evident that the capacity of the heater is limited to the maximum safe loading on this section of the coil, since any endeavor to increase the work of subsequent sections by increasing the fire would result in burning the tubes in the already fully loaded section. For a time it was believed that tube failures were caused by the effect of radiant heat, and designs were made with shielded tubes in an endeavor to avoid the difficulties encountered. Still later, however, it was realized that the transfer of heat by radiance was desirable, if properly controlled, which led to the design of the more modern tubular heaters where the heating elements are generally divided into two sections, the first receiving heat mainly by radiation, while the second is heated by direct contact with the flowing stream of product of combustion.

The problem of transferring heat to oil differs materially from that of transferring of heat to water in view of the wide boiling range of crude oils and distillates and the danger of depositing coke on the inside of the tube if the transfer of heat is too rapid. It is known that, with adequate velocity, transfer rates as high as 10,000 or 12,000 B.t.u. per hr. per sq. ft. of heating surface are possible and these rates are actually being obtained in practice on certain portions of the surface in pipe stills. With the usual design of heaters, however, the average rate of transfer for the whole apparatus is much less, usually of the order of 3500 B.t.u. per sq. ft., since the load is not evenly distributed throughout the heating surface. More even distribution has been sought by the use of recirculating flue gases and the wasteful practice of employing excess air in combustion.

One of the chief aims of the design lies in increasing the average transfer rate for the total surface rather than to increase the maximum safe loads per sq. ft., although this may be found possible later. This condition can be approached by transferring the bulk of the heat, and in some cases all of the heat by radiation, and arranging the absorbing surface in such manner that it will receive as nearly as possible an equal portion of the heat radiated. The transferring of heat from the flame direct to the absorbing surface by increasing the flame temperature, caused by reducing the excess air to a minimum and preheating the air required, permits not only an even distribution of heat to the absorbing surface but is a simpler and more economical method of utilizing fuel.

Perhaps the most radical departure found in the new design is the elimination of the conventional brick-lined combustion space, to permit the absorption of heat to begin immediately after its generation. This has led to a new arrangement of the heating surface where the flame from the burner is exposed directly to what might be considered an excess of heating surface. With this arrangement the flame heats the tubes by radiance, and, conversely, the tubes cool the flame. Thus a balance can be struck between these two factors which results in limiting the maximum temperature to which the tubes may be subjected in service. It is thus possible to operate the heating surface under conditions known to be safe by former practice, and at the same time to burn fuel with high flame-burst temperatures.

In general terms, the vertical tube heater comprises what may be termed a radiant section and an economizer section. The radiant section is constructed in the form of a vertical cylindrical shell, the walls of which are lined with vertically disposed tubes, symmetrically spaced with respect to the center of the cylinder. A burner admits fuel at one end of the vertical chamber, and the products of combustion are discharged at the other end and carried to the economizer section through a suitable flue. The economizer section may consist of a more or less conventional tube-still arrangement for the tubes or may, in some cases, be an air heater which would replace the tube bank. The firing may be effected downward or upward according to the duty intended.

Fig. 1 shows a downshot type with the economizer section disposed vertically and the horizontal flue connection between the two sections continued into the base of the stack to provide an outlet for emergency.

The vertical section is formed by a cylindrical steel shell sup-

[1] Consulting Engineer. Mem. A.S.M.E. Luis de Florez was born in New York City in 1889. He obtained his school education in France and Spain, and was graduated from Massachusetts Institute of Technology, with the degree of B.Sc. in Mechanical Engineering in 1912. Upon graduation he entered the aviation field, in design, construction, and operation of airplanes, with Burgess Company and Curtiss Company at Marblehead, Mass. In 1913 he went with W. A. Hall, as chemical engineer; later he was chief engineer of the Motor Petrol Company. In 1915 he went with the Anglo-Persian Oil Company designing plants for the Russian and British Governments for the manufacture of toluol and benzol from petroleum, returning to America in 1916, designing, erecting, and operating cracking plants for the Texas Company at Bayonne, N. J. During the war he was head of the Instrument Division of the Aviation Section, Bureau of Construction and Repair, U. S. Navy. In 1919 he was engineer for Cochrane, Harper & Co. and consulting engineer for New England Oil Co. and Invincible Oil Co. and in 1923 chief engineer of New England Oil Company. Since 1923 he has been a consulting engineer.

Presented at the Metropolitan Section Meeting, New York, N. Y., April 16 1929, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

ported on columns and provided with a lining of insulating brick and firebrick. The upper portion of the shell is provided with an angle section turned inward which supports the weight of the tube sheet and tubes. This is allowed to slide on the surface of the supporting section to compensate for expansion.

The tube sheet itself is composed of a number of sectors, usually of cast metal, rigidly connected to an inner ring made of boiler plate, uniting them into a continuous circular shape. The tube

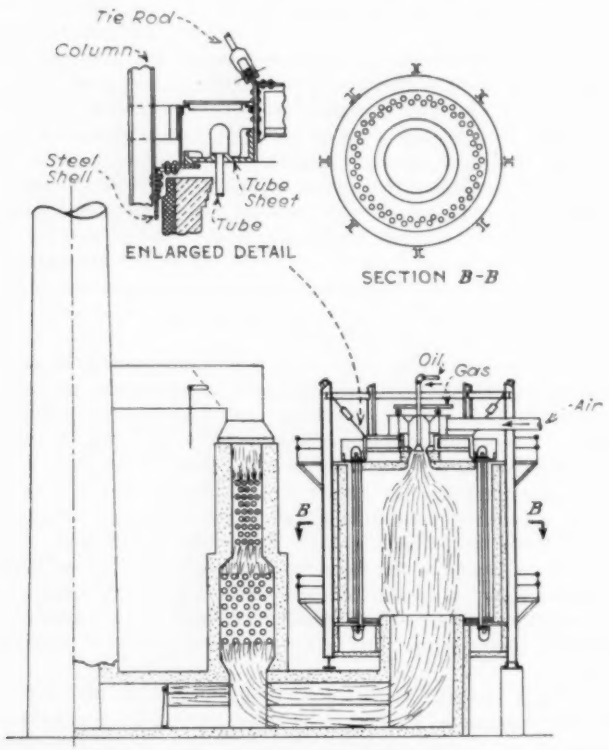

FIG. 1 DOWNSHOT TYPE WITH VERTICAL ECONOMIZER SECTION AND HORIZONTAL FLUE CONNECTION

sheet is perforated to permit the insertion of the tubes which it supports, and is so designed as to be self-supporting. Owing to its circular form it cannot break inwardly without stressing the inner annular ring of metal which joins the casting, and at the same time is free to move laterally as a whole. The burner or group of burners is supported at the center by radial members, and a flat arch is suspended from the radial members to form the top of the combustion chamber. The base of the chamber is provided with a circular opening of smaller diameter than the chamber connected with the flue, which forms the outlet passage for the products of combustion.

A second tube sheet in the form of an annular ring is provided at the base of the chamber with perforations corresponding to the top tube sheet. This lower tube sheet is supported by the shell on the outside, also by the structure formed by the outlet flue on the inner side. In this particular design, the whole of the weight of the tubes is taken by the top tube sheet, the bottom tube sheet acting merely as a support for the lining of the shell and the refractory material for its own protection. The tubes are thus permitted to expand and contract freely in a vertical direction, and their weight tends to keep them straight, eliminating the tendency to sag.

It will be noted in this arrangement that the position of the tubes is such that they are substantially out of the direct path of the products of combustion which tend to channel through the center, at the same time they are in full view of the flame. The return bends or junction boxes connecting one tube to the other are shielded from the fire by the tube plates, and housed in by side plates and removable covers which provide access for cleaning.

The tubes are usually connected in series to form a single coil to insure positive flow of the oil, but they can be divided to provide a multiple flow, if desired. In the series heater, the oil is admitted to the top of the economizer bank, passes downward progressively toward the hotter zone, and from thence is led to the inlet tube of the vertical section around the circle and out.

It will be seen from this general arrangement that all the tubes in the vertical section receive a large amount of radiant heat, while, due to their symmetrical arrangement with respect to the fire, they all receive an approximately even amount of radiation. Of course, as the oil becomes heated and the temperature of the tubes increases, the hotter tubes will absorb somewhat less heat than the cooler tubes, which is advantageous as it relieves the heat load on the tubes which might be expected to give the most trouble. The absorption of heat in the vertical section is sufficiently great to reduce the temperature of the gases delivered to the economizer section to 1200 to 1400 deg. fahr., a temperature at which they can be readily handled with a conventional setting.

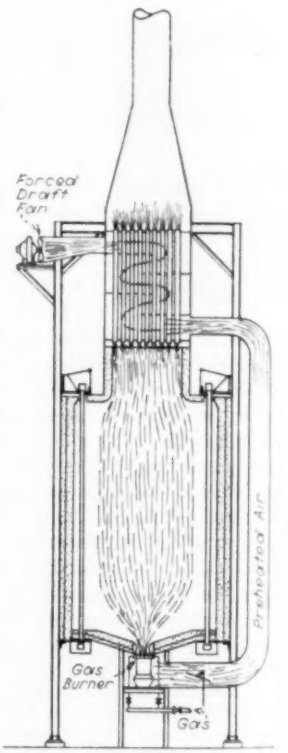

FIG. 2 UPSHOT HEATER WITH ECONOMIZER SECTION REPLACED BY AIR HEATER

With a comparatively large absorbing surface in the vertical section, the products of combustion are cooled very rapidly, making it possible to maintain a high heat gradient between the flame temperature and the average temperature of the gases surrounding the tubes, and further, by proportioning the amount of absorbing surface to the amount of fuel to be burned, it is possible to limit the maximum skin temperatures of the tubes independent of the flame-burst temperatures.

Actually the temperature at a point 10 in. to 12 in. away from the tubes toward the center of the furnace will seldom exceed 1500 deg. fahr., with flame temperatures of 2700 to 3000 deg. fahr., which appears to be a safe limit for tubes carrying oil. In existing installations, the temperatures usually run materially lower than 1500 deg. fahr., and it has been found that the variations in temperature in the length of the chamber are seldom over 100 deg. fahr. Average transfer rates for the whole surface of between 5000 and 8000 B.t.u. per sq. ft. are possible with heaters of this type, depending on the size of the economizer section, which reduces the average.

Another effect resulting from the rapid absorption of heat is evidenced by the reduction of the volume requirements for combustion made possible by the correspondingly rapid contraction of the products of combustion. In the conventional pipe still it is seldom possible to liberate more than 8000 B.t.u. per hr. per cu. ft. of combustion space, and it is probable that 6000 B.t.u. would be a fairer estimate for the average setting. It has

been possible to liberate from 15,000 to 16,000 B.t.u. per hr. per cu. ft. in a tube still of the type described and to continue to do so over long periods of time without endangering the tubes or interfering with combustion. It seems probable that this figure can be materially increased.

Doubtless these figures seem moderate when compared with boiler practice. In oil heating, however, they represent substantial progress.

In oil heating, where tube temperatures are usually higher than in steam practice, and where there is likely to be deterioration of the surface due to oxidation, another advantage results from operation with minimum excess air, apart from the standpoint of economy. The life of the tubes is materially increased by reducing the amount of free oxygen in the gases, and although there always appears to be a slight oxidation at high temperatures, the benefits of running with a minimum of excess air are very marked. In one particular installation, made on a high-temperature cracking plant, tubes have been in service about two years without substantial oxidation when running at oil temperatures of 1050 to 1100 deg. fahr., and where the outside-skin temperature of the tube is materially in excess of this figure.

There has been, to date, very little occasion to effect repairs on brickwork of furnaces built; in fact, the brickwork of the lining, flues, and economizers has shown practically no effects of heating.

In order to provide adequate surface in the combustion chamber, it is usually customary to stagger the tubes to form two rows in such a way that the inner row does not shield the back row from the flame. This usually leads to a staggered arrangement which is very flexible and permits varying the surface with standardized shells and obviates the necessity of making numerous general designs for different requirements in duty. The addition of 1 ft. on the diameter gives roughly 3 ft. on the tube sheet which leads to economy in the large sizes.

Vertical stills are now being built with a range of capacity between 12,000,000 B.t.u. per hr. and 40,000,000 B.t.u. per hr. The larger size stills have a shell diameter of about 20 ft. and a tube length of about 25 ft. in the combustion chamber with the steel work in the economizer in proportion. It is interesting to note that the cost of materials increases at a very moderate rate with capacity owing to the form of the structure, and it is expected that the larger sizes will show a substantial economy in materials per unit of capacity.

Visibility of the tubes, which is important especially in cracking, is provided by peep holes in the side of the shells, and the tubes can be viewed by looking diagonally across the furnace from various points symmetrically disposed in the shell. In the larger furnace top and bottom peep holes are also provided to view the flame.

Access to the tubes for cleaning is provided by removable covers enclosing the top and bottom tube space. The junction boxes connecting the tubes are provided with the usual removable plugs to permit turbining the tubes in place. This operation is carried out from top to bottom, and, due to the disposition of the tubes around the circumference of the combustion chamber, a large number of cleaners can be employed simultaneously, if desired, without interfering with each other. With certain types of junction boxes, dirty tubes can be withdrawn by means of an overhead trolley or crane and replacement effected in a remarkably short time. Rapid cleaning is often important since the furnace is usually connected to a large amount of equipment which must remain idle during cleaning periods and therefore non-productive.

The vertical still controls with great rapidity, and at the same time it appears to be unusually stable. The moderate variations of fuel required to maintain desired outlet temperatures do not seem to affect the percentage of CO_2 to any great extent and the control of the heater can be normally effected without changing the forced-draft pressure. It is interesting to note that if the CO_2 falls off, more load is put on the economizer, and, whereas the outlet temperature of the heater may remain constant, the outlet temperature from the economizer to the vertical section may vary considerably. In this manner changes in combustion conditions may be noticed quickly on the control board of the refinery

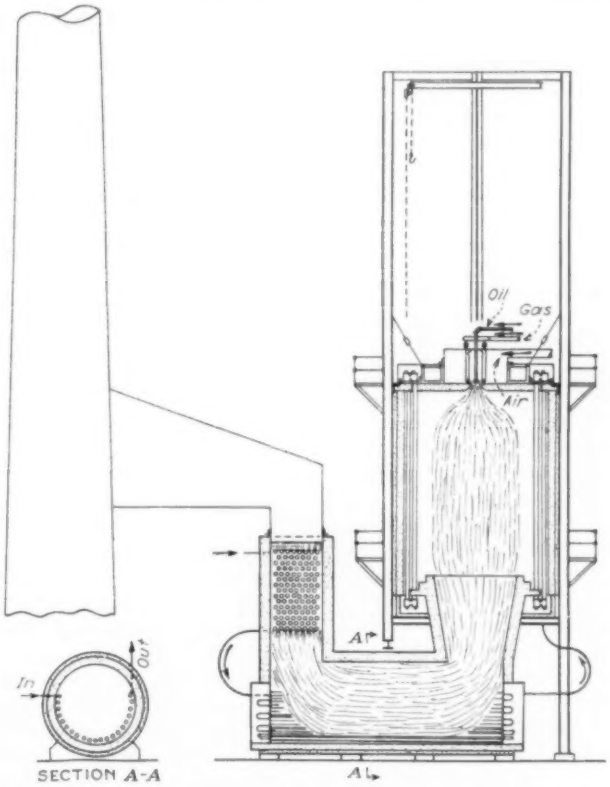

Fig. 3 Recent-Type Heater With Horizontal Flue Forming Secondary Radiant Section

unit and corresponding corrections made. Over two-thirds of the work of the heater is done in the vertical section, the remainder in the economizer. Without the economizer an efficiency of the order of 50 per cent may be expected. Under service conditions an overall efficiency of 70 to 75 per cent can be readily obtained, and it is possible that even better results can be secured when oil-inlet temperatures are not too high.

Fig. 2 illustrates an upshot heater in which the economizer section has been replaced by an air heater, shown more or less diagrammatically above the vertical section. The purpose of the air heater is to reclaim heat from the stack gases and transfer to the air required for combustion. With preheated air it is obvious that higher combustion temperatures will be obtained and therefore more heat will be made available for transfer to the tubes by radiation. This type of heater, many of which are now in operation, is of considerable interest since it carries out more fully the idea of transferring heat from a source at high initial temperatures. It is used in connection with processing where the inlet-oil temperature is of the order of 800 deg. fahr., a temperature which would render a tubular economizer section of little value. In installations of this type average heat-transfer rates for the surface run as high as 10,000 B.t.u. per sq. ft.

The mechanical structure of the heater is very simple, requiring little ground space, and it seems probable that it will lead to

considerable economy in materials. The comparatively short length of travel of the oil should permit high velocities without undue pressure drops, thereby enhancing the transfer rate of heat from metal to oil and reducing the steam required for pumping.

Fig. 3 shows a more recent modification of the type of heater first described. The chief points of interest in this design lie in details of construction, in particular in the use of the horizontal flue to form what may be termed a secondary radiant section.

PME-53-3

Use of Superheated Steam in Oil-Well Drilling

By V. WEAVER SMITH,[1] NEW YORK, N. Y.

Advent of deep drilling for oil has greatly increased the size of the equipment necessary for drilling. The cost of equipment has been mounting very much faster than the return from the wells. Furthermore, the transportation of this heavy equipment is becoming a serious problem. These factors have turned the oil industry to the engineer for assistance in solving the problem of reducing the cost of drilling wells.

Conditions have become so serious that in spite of the fact that the driller pays nothing for his fuel, he is now able to buy power in some cases from public utilities, who pay for this same fuel, more economically than he can produce it. This condition has been brought about because little attention has been paid to decreasing the initial cost and increasing the life of the equipment. Utilities have overcome the fuel cost by more efficient design and operation of the power-plant equipment. The producing industry is in an excellent position to reduce the cost of drilling wells by taking advantage of the improvements that utilities and other industries have made in design of power equipment. By so doing they will recover the advantage of low or no fuel cost, and thereby reduce the cost of drilling.

UP UNTIL a short time ago, as equipment failed or did not seem powerful enough, the tendency was to build it heavier or build it larger. Very little attempt was made to build the equipment more efficient and make it capable of doing more work without increasing its size and weight.

As an example of this the single engine was replaced by a twin engine, and, more recently, the size of the cylinder was increased from 10 in. by 10 in. to 11 in. by 11 in. and finally to 12 in. by 12 in. The size of fluid pumps increased from 10 in. by 4 in. by 12 in. to 15 in. by 7¾ in. by 20 in. In very few instances has any attempt been made to reduce the power required or the weight per unit of work produced. Hence the boiler plant has increased to meet the larger steam demand from two 73-hp., 175-lb. boilers to four 125-hp., 350-lb. boilers necessary to operate a rig.

Steam is the ideal power medium for drilling for many reasons. It gives more flexibility to the ever-changing demands for power over a day's operation. Fuel is invariably available at the location, and water is required for drilling the well. Hence, with all the raw materials necessary for supplying power on the location, the cost of transportation of any other power medium should be overcome very readily by the efficient use of the power medium. Electric power is not available at many locations, particularly in new pools where drilling is often competitive. By standardizing on equipment of one power medium that is usable under all conditions, and developing its efficiency to the highest degree, the initial investment in equipment is reduced, and the problem of replacements is greatly simplified.

The principal reasons for the slow introduction of efficiency into steam power-plant equipment for drilling have been twofold: (1) Most refinements in power-plant equipment have been looked upon as fuel savers and the driller has no fuel cost, (2) until recently the size of the power plant was too small for most refinements to justify their cost. With the heavy power demands of modern drilling and the rapid strides made in power-plant engineering, this condition is now entirely different.

Furthermore, in analyzing the advantages and disadvantages of any piece of equipment it is often necessary to go into detail. For instance, while it is commonly supposed that the reason for using superheaters on locomotives is because of the large saving in fuel and water, it will probably be found on careful analysis that the increase in the capacity of the locomotive and other factors would alone more than justify the investment. And so in considering the use of superheaters for oil-well drilling, a careful analysis of the whole problem must be made. Before considering the advantages it may be well to consider what superheated steam is and how steam is superheated.

Superheated Steam

Steam is superheated when it has been heated above the temperature corresponding to the saturation temperature. The temperature difference between superheated steam and saturated steam at the same pressure is known as the degree of superheat.

Steam that is superheated contains no moisture, and cannot condense until its temperature has been lowered to that of saturated steam at the same pressure. Superheated steam is a more efficient medium than saturated steam for transforming heat energy into mechanical energy and, therefore, fuel into power.

How Steam Is Superheated

Steam is superheated by adding heat to it, after the steam is removed from contact with water. Usually the steam is passed through a vessel located in the path of the furnace gases. Sometimes separate sources of heat are employed. Steam may be superheated or reheated in reheaters or steam resuperheaters while passing from the high- to the low-pressure stages of large turbines, where the heating agent is live steam. Superheaters with separate furnaces, known as separately fired or portable superheaters, sometimes are employed.

Steam can be superheated by throttling. This method, however, is a special instance and is not ordinarily employed, since

any degree of obtained superheat is at the expense of reduced pressure.

A Steam Superheater

A steam superheater is an apparatus to increase the temperature of steam without increasing its pressure. It is used generally for raising the temperature of saturated steam direct from a steam boiler. It consists of a system of tubular units or elements with the steam flowing inside and hot gases outside. One end of each tube or unit is connected to a distributor or saturated-steam header, the other end to a collector or superheated-steam header.

A superheater as shown in Fig. 1 for oil-country boilers consists primarily of:

1 A special cast-steel header comprising two compartments, one acting as the distributor for the saturated steam coming from the boiler, and the other for the collection of the steam after it has been superheated, and from which the steam is carried to the main steam line.

2 Detachable units of heavy-gage, seamless, drawn, steel tubing, which are formed by bonding two or more lengths of tubing by forged return bends. These units are connected to the header by means of clamped metal-to-metal ball joints.

3 Connecting pipe between the boiler nozzle and the saturated-steam inlet, safety valve, and bleeder valve.

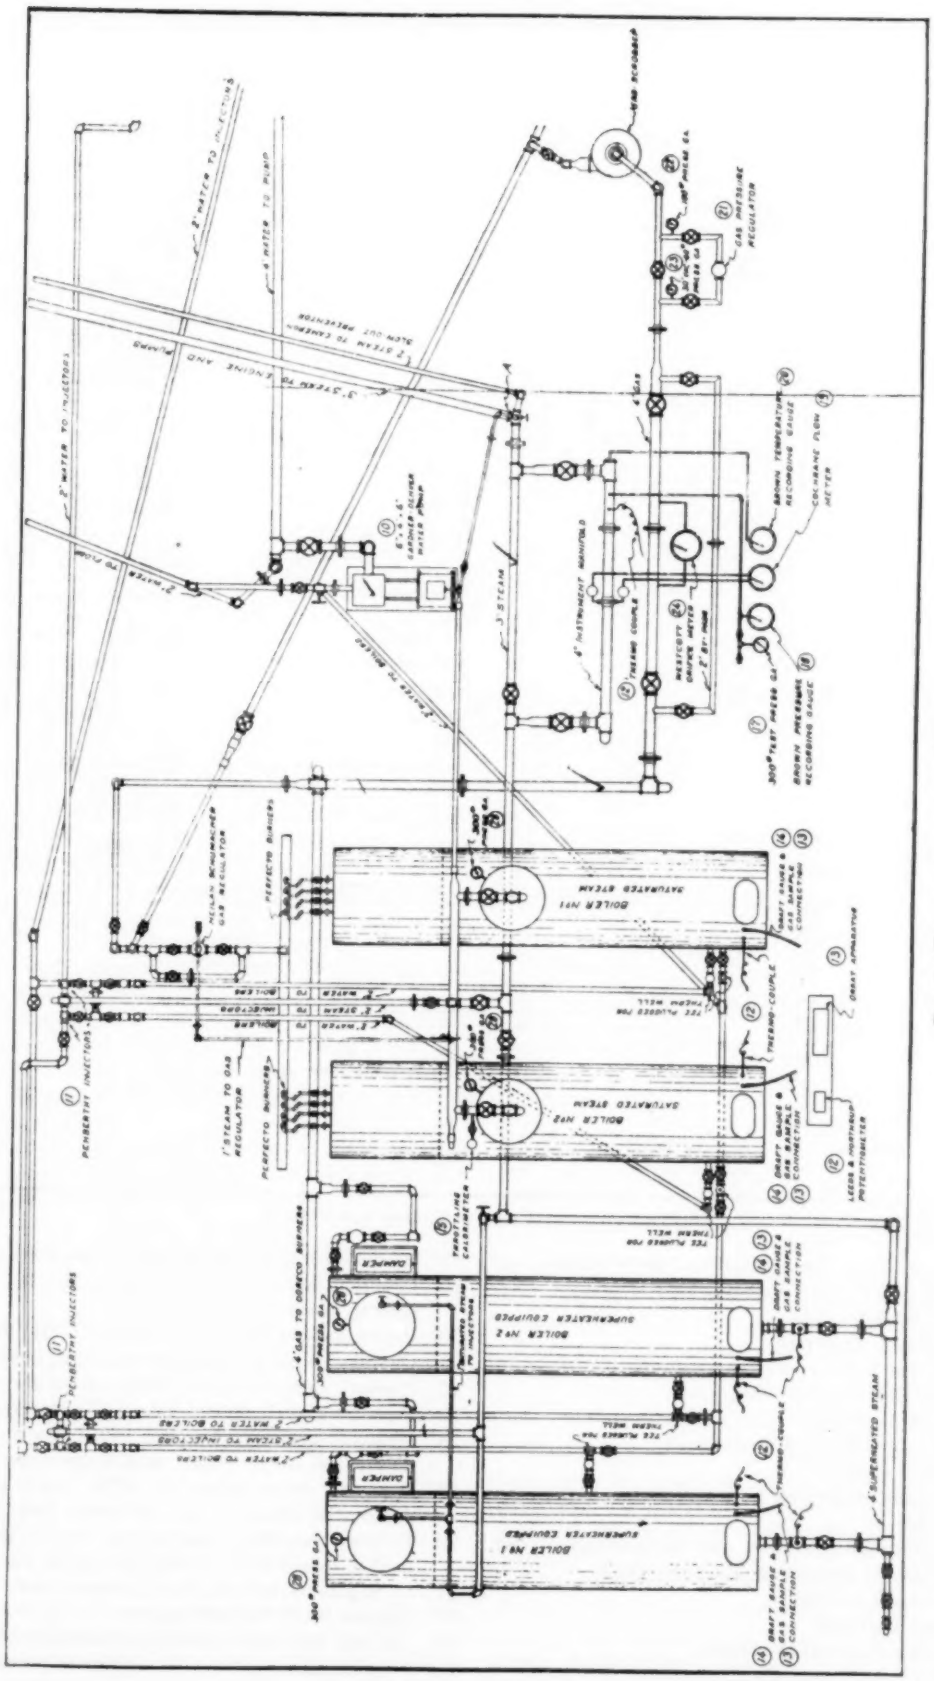
Effect of Superheated Steam in Oil-Well Drilling

A careful study of drilling operations was made to determine if superheated steam offered any advantages over saturated steam. This investigation indicated that the use of superheated steam would offer the following advantages:

1 By reducing the steam consumption of the drilling engine and the fluid pump
2 By reducing radiation losses in pipe lines from boilers to the drilling rig
3 By reducing the steam pressure of the boilers for required steam pressure at the engine and pump
4 By increasing the pressure of the fluid pumped to the well
5 By increasing the capacity, speed, and flexibility of the drilling rig
6 By increasing the life of the pumps, engines, and boilers, due to better operating conditions
7 By decreasing weight of boilers required to operate the rig
8 By decreasing the amount of water required for boilers with corresponding reduction in scale formation
9 By reducing the fuel consumption
10 By increasing the boiler efficiency.



Most of these advantages can be determined theoretically or from experience in other industries. But in order to test in a practical way the use of superheated steam under actual drilling conditions, two boilers were built and equipped with superheaters. The set-up was made as later described in detail so as to approach normal operations as far as possible.

The boilers were set up according to the common practice used in the Gulf Coast fields. The arrangement is shown in Fig. 2. A 3-in. line connected the steam header of the saturated-steam boilers to the rig. The boilers equipped with superheaters were set up in the same manner with a connection from their header, which is in front of the boiler, to the 3-in. line running to the rig. Valves were provided so that either set of boilers could be cut in or out at will without interfering with the operation of the rig. A manifold was provided between the boilers and the rig in which were installed connections for recording pressure, temperature, and the flow of steam from either set of boilers.

A second manifold, as shown in Fig. 3, was provided on the branch line going to the pump in which connections were made for measuring the steam consumption of the pump. Provisions were made for measuring the moisture and temperature of the steam at the boilers, engine, and pumps. Steam gages were provided to register the steam pressure at those points.

Water was ordinarily supplied to the boilers by means of injectors. The water was taken from a common source of supply, namely, two 250-barrel tanks. A 6 × 4 × 6 duplex pump was provided for supplying feedwater in emergencies. No feedwater heaters were used.

Casinghead gas was used for fuel of approximately 1400 B.t.u. quality. This gas was passed through a centrifugal scrubber to remove any oil or water carried over from the separator. The gas was measured by means of an orifice meter. The supply of gas to the boilers was controlled by means of the Doreco boiler governor on the superheater-equipped boilers, and by means of the Neilan-Schumacher spring-type governor on the saturated-steam boilers. Provision was made at the smoke-box of the boilers for measuring the flue-gas temperatures and making flue-gas analyses. The arrangement of the equipment and the location of the instruments are shown on Figs. 2 and 3.

Method of Conducting the Test

Since the purpose of the test was to obtain a comparison between superheated steam and saturated steam for the drilling operation, each set of boilers (two each) was operated for alternate periods of 24 hr. throughout the duration of the test. The test was started when the well was at a depth of approximately 1800 ft. and discontinued at a depth of approximately 4000 ft. The test was carried on for 18 days to be sure of obtaining average drilling conditions at the well while both kinds of steam were supplied. Readings of steam pressure, temperature, speed, fluid pressure, moisture in steam, steam and fuel consumption, etc., were taken every half hour throughout the test.

In order to eliminate the advantage of steam pressure of one kind of steam over the other, the automatic fuel regulators were set to obtain the same pressure at the point of measuring the flow of steam on both sets of boilers.

The entire test was conducted under normal drilling conditions. Throughout the test period no interruption to the drilling operation was caused by running the test. The operation of the drilling rig and the firing of both sets of boilers were done by the regular drilling crew.

Data on the boilers, engines and pumps, and at the instrument manifold were collected at half-hour intervals throughout the run. The data collected are shown in Tables 2, 3, 4, and 5.

TABLE 2 DATA TAKEN AT BOILERS[a]

	Saturated steam	Superheated steam

[a] Saturated boilers operated at average rating of 167 per cent and superheater-equipped boilers at average rating of 228 per cent.

Results on Pumps and Engines

It can be seen from the foregoing data that the hydraulic horsepower developed, which can be used as a measure of the work done by the steam, was increased with a corresponding reduction in the steam consumption of the rig. Hence it is necessary to calculate the savings in fuel, water, and the increased capacity in terms of the work done to appraise the full benefit derived from the use of superheated steam.

From the foregoing table it is seen that the hydraulic horsepower of the pump increased 16.3 per cent when superheated steam was used; hence:

9053 × 1.163 = 10,528.64 lb. of saturated steam to develop 106.3 hp.
8,010.00 lb. of superheated steam to develop 106.3 hp.

2,518.64 lb. saving in steam, or a decrease of 23.9 per cent in the quantity of steam required for the same work done.

Fig. 4 is a water-rate curve, plotted from the data taken on the pump for the different horsepower developed under changeable conditions. This curve indicates that as the fluid horsepower is decreased, the savings due to superheat increase rapidly. At a load of 60 hydraulic horsepower the water rate is reduced from 112 lb. of saturated steam per hour to 64 lb., or a saving of 43 per cent.

While the water rates may not be true figures, they are comparative since they were determined the same way for both kinds of steam. The hydraulic horsepower developed was figured from the speed, displacement, and pressure developed by the pump. Since there is bound to be some slippage of the pump, both steam rates per hydraulic horsepower should be increased 25 per cent or more to represent actual steam rates.

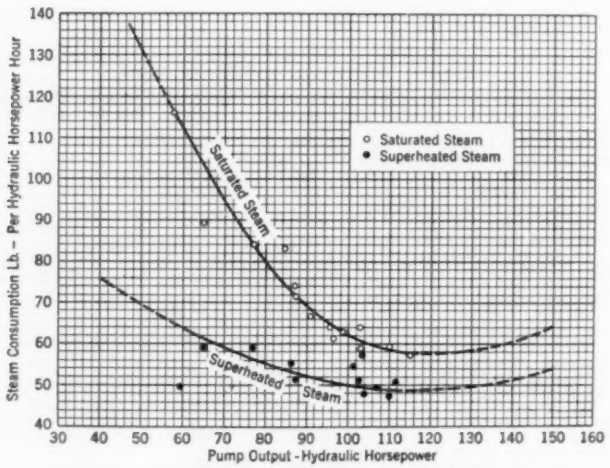

FIG. 4 STEAM CONSUMPTION OF THE MUD PUMPS
(When operated with steam furnished by the saturated-steam boilers and the superheater-equipped boilers.)

The question has often been raised as to how it is possible for there to be such a large saving in steam in a cylinder with superheated steam when no expansion takes place. It is because in uninsulated cylinders the heat radiation is so great. This can be seen from the curve. The slower the pump is running, the greater is the time per stroke or the time the steam is exposed to radiation or cooling.

Likewise, the starting of the piston to move in the opposite direction is a relatively large part of the total time of the stroke. Hence, a pump with a short stroke with saturated or superheated steam is less efficient than a long-stroke pump, all other things being equal.

Since there were no easy means of measuring the work done by the engine without interfering with the operations, no measurements were taken. Since the engine is a reciprocating type, taking steam for the full stroke, superheated steam would be expected to show an equal decrease in the quantity of steam required.

The speed of operation and the flexibility were improved due to the elimination of moisture from the engine. The saturated steam contained 17 per cent of moisture, while the superheated steam still contained some 50 deg. of superheat at the engine. It was observed that it was necessary to pick up several more "thribbles" in low speed with saturated steam than with superheated steam. This reflects the improved operation of superheated steam.

Losses in Steam Lines

The steam line from the saturated boilers to the pumps consisted of 44 ft. of 4-in. standard line pipe and 219 ft. of 3-in. standard line pipe, together with twenty 90-deg. angle fittings. The steam line to the engine consisted of 19 ft. of 4-in. pipe and 210 ft. of 3-in. pipe, together with thirteen 90-deg. angle fittings.

The steam line from the superheater-equipped boilers to the pumps consisted of 50 ft. of 4-in. standard line pipe and 244 ft. of 3-in. standard line pipe, together with twenty-one 90-deg. angle fittings. The steam line to the engine consisted of 25 ft. of 4-in. pipe and 235 ft. of 3-in. pipe, together with fourteen 90-deg. angle fittings.

The lines would have been considerably shorter under normal operating conditions, and would have contained less 90-deg. angle fittings. The longer lines and increased number of fittings were necessary to install the manifolds for test purposes.

The radiation losses in the case of superheated steam amounted to 610,000 B.t.u. per hr. and for saturated steam 1,350,000 B.t.u. per hr. These losses are equivalent to 18.2 boiler horsepower for the superheated steam and 39.3 boiler horsepower for the saturated steam.

The average pressure drop between the instruments on the manifolds at the boiler and the pump was 17 lb. for superheated steam and 26 lb. for saturated steam. This line consisted of 200 ft. of 3-in. standard line pipe with eleven 90-deg. angle fittings.

For safety reasons the use of superheated steam, therefore, permits the boilers to be placed at a greater distance from the rig for the same amount of heat and pressure losses. However, for maximum efficiency, the steam lines should be as short and as free of turns as possible.

Results Obtained on Boilers

No attempt was made to conduct an accurate thermal-efficiency test on the boilers, but readings of the fuel consumption, steam output, flue gas, and feedwater temperatures were taken periodically. The saturated-steam boilers operated at an average output of 9053 lb. of steam per hr. or 308 hp., which is 167 per cent of their rated (92 hp.) capacity. The superheater-equipped boilers were operated at an average output of 8010 lb. per hr. or 297 hp., which is 228 per cent of their rated (65 hp.) capacity. At these average operating conditions, the flue-gas temperatures for the saturated-steam and superheater-equipped boilers were 697 deg. and 700 deg. fahr., respectively.

From the data it can be seen that the fuel required to operate the rig with saturated steam was 14,017 cu. ft. per hr., while with superheated steam only 12,011 cu. ft. were required to operate the rig at 16.3 per cent increased capacity, hence:

14,017 × 1.163 = 16,301 cu. ft. required to do same work with saturated steam
12,011 cu. ft. required to do same work with superheated steam

4,290 cu. ft. fuel saving per hr., equivalent to 26.3 per cent in fuel for same work done.

From the data it can be seen that the average steam required to operate the rig with saturated steam was 9053 lb. per hr. With superheated steam it was 8010 lb. per hr. Since the steam used is equivalent to the water evaporated, the saving in water consumption can be calculated as follows:

9053 × 1.163 = 10,528 lb. water evaporated to do same work with saturated steam

8,010 lb. water (when superheated steam was used)

2,518 lb. water saving, or a decrease of 23.9 per cent in the quantity of water required.

Since scale formation is directly in proportion to the water evaporated, it can be said that there is a reduction of 23.9 per cent in the scale deposit.

The overall thermal efficiencies of the saturated-steam and superheater-equipped boilers were 52.8 per cent and 59.4 per cent, respectively. The saturated-steam boilers had previously been used to drill 9100 ft. of hole and the superheater-equipped boilers had been used to drill 4000 ft. of hole. On a preliminary test these two superheater-equipped boilers developed 393 hp. under maximum firing conditions and without consideration of efficiency. This represents 325 per cent of the rating.

With the reduction in water evaporated to operate the rig, it is obvious that the scale deposit in the boiler is reduced a corresponding amount. This results in less foaming of the boiler, and decreases the amount of blowdown on the boiler.

Since less steam is required for drilling, and more pressure is developed by the mud pump by the same steam pressure when using superheated steam, it is apparent that smaller boilers can be used to perform the work required. This will reduce the difficulty and cost of transporting the boiler in the field, and also reduce the working pressure of the boiler. The superheater-equipped boilers were unloaded at three different locations in running the preliminary and final tests. In transporting them, due to bad roads, they were thrown off the trucks on one trip. During transportation, the superheaters were not removed from the boilers. No leaks or other mechanical troubles developed in the superheaters although the boilers did leak somewhat. This leakage in the boiler was probably due to excess operating pressures when attempting to carry the load at the preliminary test location. This indicates that no trouble in transportation is to be expected with superheater-equipped boilers.

The elimination of excessive moisture by the superheated steam from engine and pump and the better lubrication indicated that the life of this equipment would be longer than with saturated steam. The decrease in scaling troubles of the boilers will increase the life of the tubes and the entire boiler. Lower operating pressures will have the same effect.

It can be seen from the data taken that the capacity of the rig is increased 16.3 per cent by the use of superheated steam. This will result in decreased drilling time in drilling wells. With more holes drilled per rig, the entire investment in drilling equipment can be reduced. When drilling offset wells, the increased capacity due to superheated steam is particularly advantageous.

Operating Conditions When Using Superheated Steam

Neither of the firemen at the well on which the preliminary test was run, or when conducting the regular test, experienced any difficulty in operating superheater boilers. They seemed well satisfied with them. Superheater-equipped boilers are fired in exactly the same manner as saturated-steam boilers except that when firing up, a bleeder at the outlet of the superheater must be left open to permit passage of sufficient steam to protect the superheaters until they are put on the line.

No difficulties of any nature were encountered in operating the rig. No special knowledge is required of the operators in using superheated steam. It is to be noted, however, that a good grade of high-flash lubricating oil should be used for the engine and the pump. With superheater-equipped boilers the steam header is across the front of the boiler. When injectors are used to supply the feedwater, a small saturated-steam header is required from the dome of the boiler as injectors do not operate as readily on superheated steam.

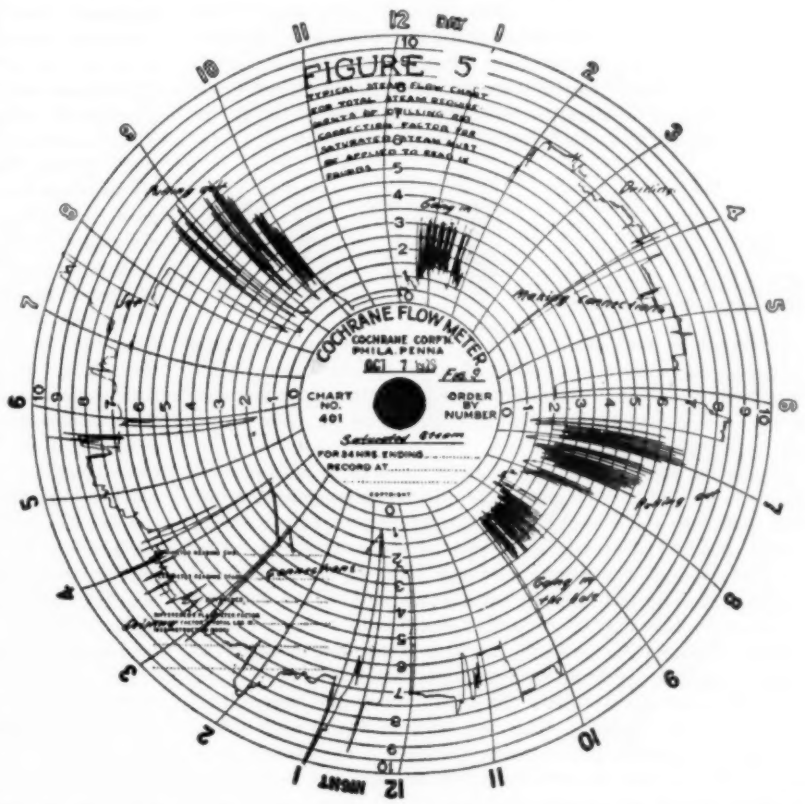

Fig. 5 Typical Steam-Flow Chart for Total Saturated-Steam Requirements of the Rig

(Variations in steam demand for the various operations on the rig are indicated.)

The superheater is of simple construction, consisting of two steam headers and units inserted in large flues in the boiler. These units are clamped to the headers with a ball joint held in place by one bolt. To replace a unit it is necessary only to open one bolt to make the change. Only two types of units are required, so the investment in replacements and number of parts necessary to stock is small.

As pointed out, no mechanical troubles were encountered in the use of the superheaters. The superheat obtained was as high at the end of the run as at the start of the preliminary run. This indicates that the units are remaining clean. In view of this, no trouble is anticipated in the life of the equipment.

It is to be pointed out that the large flues containing the superheater units cannot be swabbed out as readily as the regular tubes. This does not seem to present a serious disadvantage as they can be cleaned readily with a steam lance.

Boilers equipped with superheaters do not contain as much heating surface as saturated-steam boilers of the same size due to the large flues necessary to accommodate the superheater units. However, the increase in boiler efficiency and capacity of the drilling rig, as shown in this report, indicates that this is not a disadvantage.

It can be seen from the results of this test that the use of superheated steam gives a remarkable improvement in the operation of all the major equipment on the drilling rig. It can be seen that in addition to the fuel and water saving that can be made, the increased capacity of all the equipment without increased weight, the increased life due to better operation, increased speed of drilling, and flexibility due to superheating offer many decided advantages.

After this test was made, boilers equipped with superheaters were introduced into Oklahoma, and additional results are now obtainable. It is interesting to compare the operation given in Table 6 on rigs using the same pumps and engines, but using saturated-steam and superheater boilers, all operating at approximately the same depth of hole.

Flue-gas temp., deg. fahr.	640	635	910	870
Pump speed, cycles per min.	60	60	60	57

The burners used on these four rigs were the same, so that the flue-gas temperature is a good indication of how much harder it is necessary to fire a saturated boiler to run the rig on an equal basis. These saturated rigs were typical of all the boilers used in the Oklahoma City field.

Operating the rigs with lower steam pressure is an important factor in the life of the boiler. The question is sometimes raised as to why the speed of the pump can be maintained with lower steam pressure when operating with superheated steam. Due to the excessive condensation taking place in an uninsulated cylinder the effective cylinder pressure required is not built up as fast with saturated steam as with superheated steam. Consequently a higher line or boiler pressure is required to effect the required cylinder pressure with saturated steam.

When some operators saw the advantage of the superheated steam at 250 lb. pressure, their first reaction was to increase the pressure further to improve their operation. They found little advantage, for once the effective pressure required was met, any further pressure only increased it slightly due to the higher total steam temperature.

In the Oklahoma City fields it is quite common to see batteries of four 125-hp., 350-lb-pressure, saturated-steam boilers operating a rig. If the results of the test are considered it can be seen that three superheater-equipped boilers would not have to be operated at any higher rating than the four saturated-steam boilers to run the rig.

The comparison of weight of boilers given in Table 7, to be transported from one location to another, shows a decided advantage of the more efficient power plant.

TABLE 7 COMPARISON OF WEIGHT OF BOILERS PER BATTERY TO TRANSPORT

Weight of four 350-lb., 125-hp., saturated-steam boilers, lb.	135,064
Weight of three 250-lb., 125-hp., superheater-equipped boilers, lb.	94,419
Less weight to be transported per well drilled, lb.	40,645
Reduction in per cent in favor of superheaters	30

Boilers are moved to many locations during their life, so that this saving in transportation charges is saved many times over. When one boiler is eliminated from a battery, it is not only the boiler that is saved—all the auxiliary equipment such as burners, blowoff valves, pop valves, check valves, and gages are eliminated from the first cost as well as the cost of replacement, installation, and transportation.

By reducing the quantity of steam required, thereby reducing the water consumption, the equipment serving the boiler plant, such as feedwater pumps, condensers, feedwater heaters, fuel regulators, etc., can be smaller, thereby reducing the investment in this equipment.

The use of condensers to supply pure water to the boilers offers a big improvement by the elimination of scale. Yet condensers are not economical except in special cases because of the large quantities of water required and the high cost of the condensers. Since superheaters reduce the quantity of steam, to condense it will assist in making possible the advantages of condensed water.

In using superheated steam it is highly important that a good grade of lubricating oil be used in the cylinders. Furthermore, greater care must be exercised to see that the lubricators are kept filled at all times. When operating with wet steam, operation without lubrication for short periods may not harm the cylinder walls because the moisture acts as a partial lubricant. This is not the case, however, with dry steam, which has no lubricating properties. However, with the improved lubrication due to dry steam, the life of the cylinders will be greatly increased.

In pumps and engines using piston-type valves no difficulty has been experienced when operating at a total steam temperature of 550 deg. fahr. With slide-valve equipment such as is used in California no troubles will be encountered with a total steam temperature of 500 deg. fahr. With the improvement in metals that are now used on pumps and engines for oil-country practice, these temperatures can even be exceeded without any harm to the equipment. Most steam-pump and engine manufacturers recommend total steam temperatures of 500 deg. fahr. on slide-valve equipment and 650 deg. fahr. on piston-valve equipment.

Since the condensation in uninsulated cylinders is great, it is necessary to have from 100 deg. fahr. to 150 deg. fahr. of superheat at the cylinder to overcome the losses and secure the fullest benefit from the superheater. This, together with the line losses, makes it essential to start with from 200 deg. fahr. to 250 deg. fahr. of superheat at the boiler plant.

In California in one field which is very mountainous, where very long steam lines are used, a separately fired superheater has been tried. The purpose there has been to furnish practically dry steam at the rig, but no superheat in the engine and pumps. With covered lines this does not require a high degree of superheat, and 100 deg. of superheat has proved satisfactory in most cases. While this method reduces the load on the boilers equivalent to the line losses, the use of an additional 100 deg. fahr. of superheat would improve the operation greatly and further reduce the load on the boilers. In this particular field the water is very hard and contains a large amount of solids, so reducing the amount of water necessary to evaporate, offers a particular advantage.

Insulation of steam lines on drilling rigs presents many difficulties. While it is true that savings can be made which will justify its installation, it is always a problem to maintain insulation when frequent set-ups are made in new locations. So in the final analysis the saving is hard to prove and justify. For this reason it would appear that a high degree of superheat becomes a more practical substitute for insulation. The cost of an integral superheater for 200 to 250 deg. is very little more than one for 100 deg. of superheat. Very little additional heat is required for the higher superheat and the fuel necessary to secure it has no value. Line losses with superheated steam are much smaller than with saturated steam so that in a large percentage of the locations all the line losses can be absorbed by

the superheat, and still provide sufficient superheat at the rig to give it the full benefit of superheated steam. This system does not throw any additional load on the boilers for no condensation takes place.

Some thought should be given to the type of superheater best adapted to oil-country practice. Up until the present time the locomotive-firebox type of boiler has proved the most practical for oil-country drilling operations. In this type of boiler it is possible to install economically a superheater for high-degree superheat which will outlast the life of an oil-country boiler. This superheater is automatic in its operation without any attention necessary other than to provide a flow of steam to it during the firing-up period. Being located in the flues of the boiler it is always protected by the water surrounding the flues for all variations in load. Its weight is very little, and it can be moved with the boiler without being disturbed, so that its first cost is practically its last cost.

Separately fired superheaters for high degrees of superheat for the quantity of steam used on drilling operations cannot be built in a portable type unless a large portion of the heat is absorbed by radiation. In Fig. 5 the variation in steam flow over a day's operation is shown. Experience in other industries has demonstrated that it is difficult to protect a superheater of this type with large variations of steam flow. Automatic-firing equipment assists greatly in this protection, but failure for a very short time is usually fatal.

When separately fired superheaters are built in a permanent brick setting it is possible to afford some more protection to the superheating surface for low-degree superheat. The first cost of this type is possibly lower than any other type, and where boilers are used in one location for a long period of time they are probably economical. However, when the additional cost of piping, valves, fittings, automatic control, and the small salvage value of the heating surface and setting are considered, it is probable that when the battery of boilers has to be moved frequently the low first cost is soon dissipated.

It can be seen from the results of the test and from the operation in the Oklahoma City field that the use of superheated steam for oil-country drilling presents an excellent opportunity to reduce the cost of drilling operations.

PME-53-4

Lubrication Research Activities

Fifth Report of A.S.M.E. Special Research Committee on Lubrication[1]

A new general program for experimental work and publications recently formulated by the Committee is outlined in this report, and is followed by a brief statement of results already accomplished. Particular attention has been given to the coordination of data obtained by various investigators on viscosity under high pressure, to the study of pressure distribution in the oil film as applied to both thrust bearings and journal bearings, and to the development of methods for measuring oiliness. From experiments on the flow of liquids through very fine glass and platinum capillaries, it appears that the ordinary laws of viscosity may safely be relied upon down to a film thickness at least as small as one-millionth of an inch. The report concludes with a brief review of recent European investigations.

THIS report summarizes the work of the A.S.M.E. Special Research Committee on Lubrication over a period of three years since the previous report (Ref. 1)[2] was submitted. During the first half of this period, the investigation of the effect of the length-diameter and clearance-diameter ratios on the frictional resistance of full journal bearings was completed at the Bureau of Standards (Ref. 2), a study of oil-ring bearings was conducted by the Westinghouse Electric & Manufacturing Company (Ref. 3), and a series of experiments to test the hydrodynamic theory of lubrication was initiated by the Committee at the Pennsylvania State College. During the latter part of the same period a new general program (Ref. 4) for experimental work and publications was formulated by the Committee, as described hereafter, a substantial beginning was made toward collecting funds to support the experimental work, and accordingly some very interesting results are now being obtained.

Experimental Program

The program outlined is a continuation of the earlier work of the Committee (Ref. 1). The Lubrication Committee is chronologically the oldest one of the many existing Special Research Committees of the Society. It was organized in 1915 to investigate the fundamental problems of lubrication phenomena, to formulate results of investigations previously made, and to keep in touch with contemporary research in this field. It deals with a subject of basic importance in many different branches of engineering, including railway and marine transportation, power generation, and manufacturing industries.

The estimated requirement for effectively conducting the following program over a period of two years is $22,500. This program utilizes personnel and facilities which are already available, otherwise a larger fund would be needed:

1 Continuation of the study of viscosity under high pressure $2500
   (*a*) Preparation of a paper on coordinated results of data obtained in England, Germany, and the United States.
   (*b*) Study of practical applications, including relations to oiliness and seizure phenomena.
   (*c*) Extension to higher pressures and temperatures.
2 Journal bearing investigations $10,000
   (*a*) Study of pressure distribution in the oil film, with variations of clearance and length.
   (*b*) Determination of load-carrying capacity for commercially finished bearings.
   (*c*) Further study of the friction of small-sized bearings (up to 2⅜ in. diam.) in relation to mechanical design and other factors.
   (*d*) Development of apparatus for extension of the friction measurements to larger diameter bearings.
3 Oiliness research $10,000
   (*a*) Further development of four types of oiliness machines (Herschel, Dickinson, McKee, and Kingsbury) and comparison of results obtained from them on the same series of oils and of bearing metals.
   (*b*) Study of fundamental facts regarding effect of speed, load, temperature, and condition of the bearing surfaces upon the coefficient of friction under oiliness conditions.
   (*c*) A beginning on the difficult problem of finding the limiting thickness of film below which the properties of the lubricant are no longer the same as when tested in bulk.
4 Investigations in progress which have already been financed:
   (*a*) An experimental test of the hydrodynamic theory of lubrication at the Pennsylvania State College, using a journal-bearing machine designed by Mr. Kingsbury and loaned to the College for this purpose.
   (*b*) Experiments on pressure distribution in oil films at the Kingsbury Machine Works by means of electrical observations on large-scale models.
   (*c*) Experiments on waste-packed bearings, ring oiling and forced lubrication in the Research Department of the Westinghouse Electric & Manufacturing Company.

Publication Program

Some of the most valuable papers on Lubrication published by the Society are now out of print. The Committee has been asked to compile a representative collection of such papers for reprinting in a single volume, uniform in style with other volumes in the A.S.M.E. Research Publications Series. A number of translations and abstracts of foreign papers may also be included.

Several articles are in preparation for Mechanical Engineering and other periodicals outlining briefly the history and present status of lubrication research, as well as the elements of the mechanics and thermodynamics of lubrication.

The results of research conducted by members of the Committee or in cooperation with the Committee are made available in the form of papers presented for discussion at the regular meetings of the Society.

Status of Experimental Work

The status of work recently begun under the experimental program outlined is briefly as follows:

1 Viscosity Under Pressure. Table 1, prepared in connection with the coordination of numerical data from different sources, indicates the range of variables covered. Table 2 summarizes the data thus far obtained on the apparent solidifying pressures and corresponding temperatures. A number of very striking relationships can be brought out by mathematical and graphical representation. It may be noted, however, that no conclusive evidence has yet been obtained of the solidification of either

---

[1] The personnel of this Committee consists of Alan E. Flowers, *Chairman*, Poughkeepsie, N. Y.; Earle Buckingham, Secretary, Cambridge, Mass.; L. P. Alford, New York, N. Y.; L. J. Bradford, State College, Pa.; H. C. Dickinson, Washington, D. C.; M. D. Hersey, Washington, D. C.; H. A. S. Howarth, Philadelphia, Pa.; G. B. Karelitz, New York, N. Y.; Albert Kingsbury, New York, N. Y., and A. E. Norton, Cambridge, Mass.

Presented at the Annual Meeting, New York, N. Y., Dec. 1 to 5, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] References to literature will be found at the end of this report.

pure castor oil or a pure asphaltic-base petroleum oil. As regards the accuracy of these determinations, it may be stated that excellent agreement has been found between the diversified instruments used for the purpose of viscosity measurement, but that the agreement is not so close under the conditions of plastic flow involved in determining solidifying pressures. This was to be expected and should be further investigated when possible.

The practical applications in view will include a search for correlations with oiliness (i.e., reduced frictional resistance), wear, and seizure of surfaces operating under low speed, heavy load conditions such as roll necks, gear teeth, and cutting tools.

TABLE 1 PRESSURE AND TEMPERATURE LIMITS[3] IN VISCOSITY INVESTIGATIONS

Investigator	Lubricant	Max. press., lb. per sq. in.	Max. temp., deg. cent.
Hersey (Ref. 4)	Lard oil	7,000	20
	Mineral oil 1	3,000	20
Hyde (Ref. 5)	Neatsfoot	18,000	40
	Sperm	16,000	40
	Castor	17,000	40
	Rape seed	16,000	40
	Mineral oil 2	18,000	40
	Mineral oil 3	16,000	40
	Mineral oil 4	17,000	40
	Mineral oil 5	15,000	40
Hersey and Shore (Ref. 6)	Lard oil	50,000	100
	Castor	56,000	140
	Mineral oil 4	34,000	93
	Mineral oil 6	58,000	100
	Mineral oil 7	53,000	100
Bridgman (Ref. 7)	Oleic acid	57,000	75
	Kerosene	171,000	80
Kiesskalt (Ref. 8)	Neatsfoot	9,000	80
	Raw linseed	9,000	80
	Peanut	9,000	80
	Mineral oil 8	14,000	80
	Mineral oil 9	14,000	80
	Mineral oil 4	14,000	80
	Mineral oil 5	14,000	80
	Ref. machine	14,000	80
	Spindle	14,000	80
	St. turbine	14,000	80
	Coal-tar oil	14,000	80
	Voltol	14,000	80
Kleinschmidt (Ref. 9)	Lard oil	102,000	75
	Mineral lard	92,000	75
	Sperm oil	72,000	75
	Castor	135,000	80
	Rape seed	31,000	75
	Mineral oil 10	93,000	75
	Mineral oil 4	50,000	80
	Mineral oil 7	82,000	75

[3] Approximate values only are given in this table. The maximum pressures were not always observed simultaneously with the maximum temperatures. The lower limit of pressure was, in all cases, atmospheric. The lower limit of temperature was not in any case below 20 deg. cent. For description of oils see references cited.

TABLE 2 APPARENT SOLIDIFYING PRESSURES

Lubricant	Temp., deg. cent.	Press., lb. per sq. in.	Ref.
Lard oil	22	24,000	6
	25	38,000	9
	40	60,000	9
	75	102,000	9
Mineral lard	75	92,000	9
Sperm oil (unrefined)	25	17,000	9
	40	30,000	9
	75	72,000	9
Sperm oil (N.P.L.)	25	11,000	9
	40	26,000	9
	75	61,000	9
Castor oil[4]	20	19,000	6
	25	23,000	6
Rape seed	25	31,000	9
Mineral oil 10	25	31,000	9
	75	92,000	9
Oleic acid	30	18,000	7
Mineral oil 7	20	17,000	6
	25	24,000	9
	40	43,000	9

[4] One sample only, hence doubtful.

In preparing for the extension of observations to higher temperatures a study has been made by G. H. S. Snyder of the accuracy of the temperature measurements, especially as affected by time-lag; and the Flowers viscometer (ball-and-slanted tube) has been calibrated with a larger diameter ball to adapt it for lower viscosities. A very simple confirmation of the increase in viscosity of castor oil due to high hydrostatic pressure, and of the corresponding increase in the stiffness of soft cup greases and pressure-gun greases, has been obtained by forcing these materials through a long metal capillary discharging into the free atmosphere. The curve for rate of flow plotted against inlet pressure passes through a maximum, i.e., increasing the inlet pressure beyond a certain point reduces the rate of flow. It seems possible that this method may offer some advantages for observations under extremely high pressures.

2 Journal Bearings. A simple drill-press attachment designed by S. A. McKee of the Bureau of Standards has been used for exploring the pressure distribution in the oil film. The vertical bronze bearing is completely immersed in a bath of the lubricant and loaded by a spring balance in a horizontal position. The bearing contains one small hole suitably connected to a pressure gage. By rotating this bearing the circumferential pressure distribution can be determined at as many points as desired. The working portion of the journal is considerably shorter than the bearing, and is driven from above by a spindle of smaller diameter, so that the longitudinal pressure distribution can readily be determined by elevating or lowering the bearing relative to the journal. The line of application of the load can also be varied at will so as to investigate the effect of eccentric loading. Observations to date have shown a decided departure from the Sommerfeld distribution curves for full journal bearings without side leakage.

It is proposed to investigate the load-carrying capacity of commercially finished journal bearings by determining the location of the minimum points on the diagram in which coefficient of friction is plotted against ZN/P, where Z denotes viscosity in centipoises, N revolutions per minute, and P the bearing pressure, i.e., load per unit of projected area, in pounds per square inch. The minimum point is considered as marking the transition from stable to unstable lubrication. From the results of such tests it should be possible to prepare tables of permissible loads, corresponding to any given speed, lubricant, and temperature, for bearings that are not run in. After running in occurs, the factor of safety is considerably increased. The problem is a statistical one in the sense that a large number of tests must be made to establish reasonable limits within which the minimum point may be expected to lie.

To date the tests have been completed on two sets of white-metal journal bearings of widely differing composition. Although the load capacity as defined above was found to be very nearly the same, it is interesting to note that the bearing with the greater lead content showed a more pronounced running-in effect, i.e., the minimum point could be shifted a given distance toward the origin with a much smaller expenditure of frictional work in foot pounds.

One of the objects of the investigation of the effect of the length-diameter and clearance-diameter ratios recently completed (Ref. 2) was to provide correction factors for reconciling the load-capacity observations that might be made on commercial bearings of unequal lengths and clearances.

3 Oiliness Research. The first machine known to this Committee as being suitable for quantitative measurements of oiliness was designed and constructed by Albert Kingsbury and described, together with numerical data on several different lubricants, in a paper presented at the 1895 annual meeting of the Society (Ref. 10).

This horizontal-axis machine was later installed by Professor Kingsbury at the Worcester Polytechnic Institute, where it is hoped that further tests can be made. The horizontal machine

is particularly adapted for tests on screw threads, thrust bearings, and flat annular surfaces. It should not be confused with the vertical-axis machine developed by Professor Kingsbury at Worcester Polytechnic Institute at a later date (Ref. 11), more commonly known as the Kingsbury oil-testing machine, and in which two separate bearing blocks are pressed against the opposite sides of a revolving journal. Both of these machines were found effective in bringing out characteristic differences between the frictional resistance of different lubricants that cannot be fully accounted for by differences in viscosity. These investigations by Mr. Kingsbury may therefore be considered the first scientific contribution toward the measurement of oiliness.

Further progress, especially in cooperative efforts, required agreement on the definition of oiliness. It was clearly desirable that in comparing any two oils they should possess equal viscosities and be tested under identical conditions; but it was not self-evident whether the viscosities should be equal at atmospheric pressure or under the actual pressure of the test. From an early date W. H. Herschel had advocated the former alternative. Herschel's definition is now generally accepted. Accordingly, oiliness may be defined as the property which causes a difference in friction when two lubricants having the same viscosity at atmospheric pressure, and at the true temperature of the film, are tested under identical external conditions. The lubricant giving the less friction is considered as possessing the greater oiliness.

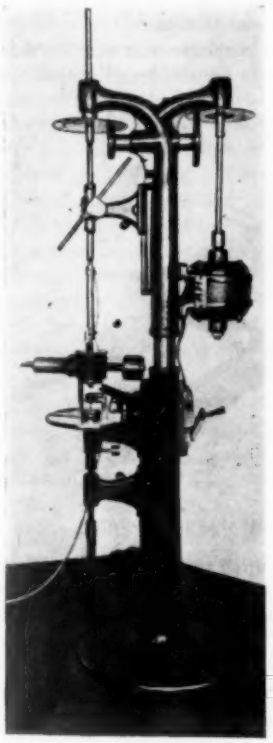

FIG. 1 KINGSBURY OIL-TESTING MACHINE

At least six types of oiliness machines are available for investigation at the Bureau of Standards, including the Herschel oiliness machine (Refs. 12–15, incl.), Dickinson grooved-specimen machine (Refs. 16, 13), Kingsbury oil-testing machine (Refs. 11, 17, 13), McKee journal-bearing machine (Refs. 18, 19, 2), Amsler wear-testing machine (Refs. 20, 21), and a slow-motion inclined plane for static-friction observations.

Among the cardinal requirements of any oiliness measuring machine are: (1) elimination of the influence of viscosity, (2) reproducibility of results, and (3) variability of physical conditions over the full range to be met in service, in so far as it may be found that the property of oiliness depends upon such conditions. It does not, however, appear necessary for the geometrical form of the test surfaces to be the same as those employed in service, any more than it would be necessary for the construction of a viscometer to resemble the construction of an engine for which the oil is being selected. In applying the results of tests on any newly defined property of a material such as oiliness, after the measurements have been completed the task still remains of establishing empirical curves to connect the performance of the machine, taken as ordinate, with the property of the material, taken as abscissa. A report on the logic of oiliness is in preparation in which it is hoped that these questions can be dealt with more fully.

The Herschel oiliness machine appears to be the simplest of those mentioned above as regards construction of the test surfaces. The friction of commercial steel balls is measured against flat annular disks of bearing metal. While the procedure for the use of the Herschel machine has not yet been fully standardized nor its limits of reliability marked out, the following typical results will indicate its applicability to show the effect of changes in chemical composition on the oiliness of a series of lubricants. Six samples of straight mineral oil and six samples of the same oils treated by the addition of a small percentage of oleic acid were obtained from the refiner for oiliness tests. These samples ranged from the lightest to the heaviest grade of automobile oil, and were tested on five types of bearing metal (bronze, brass, babbitt, lead babbitt, and cast iron). Absolute viscosities were then determined at approximately the temperature of the test, as a basis for plotting curves showing the observed coefficients of friction as functions of viscosity. The five pairs of curves thus obtained show a slight systematic decrease in friction with increasing viscosity, and a distinct reduction in friction averaging about 20 per cent, due to addition of the fatty acid.

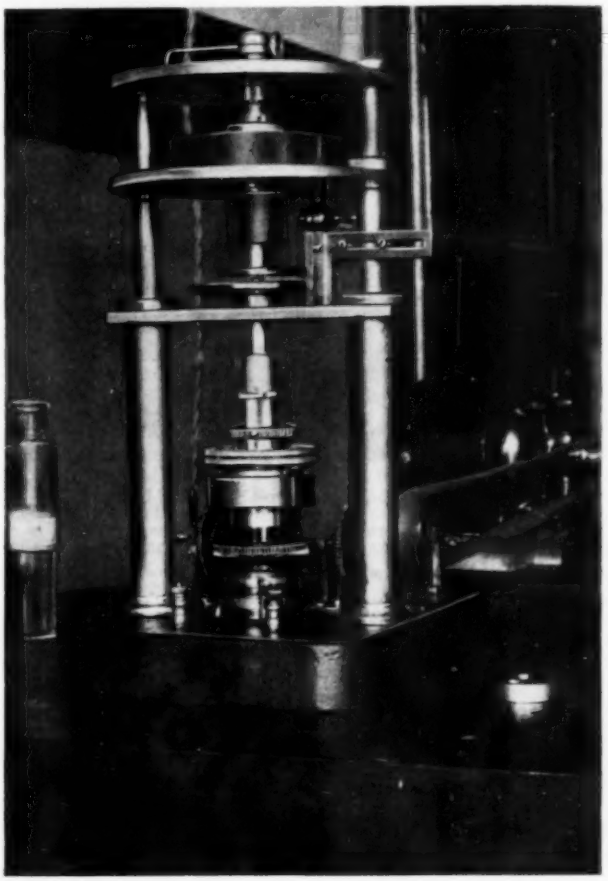

FIG. 2 HERSCHEL OILINESS MACHINE

In the procedure adopted by Mr. Herschel it is intended to eliminate or greatly diminish the influence of viscosity on the performance of the machine by choosing so low a speed for the test that the coefficient of friction, f, will be at or near its maximum value. The existence of such a maximum has been found experimentally, and it lies far below the speed corresponding to the more familiar minimum point. So far as concerns the intrusion of purely hydrodynamic action, it may be inferred that when f passes through a maximum on the speed diagram it must like-

wise do so on the ZN/P diagram, and that therefore $\partial f/\partial Z = 0$ when $\partial f/\partial N = 0$.

A collection of lubricants tested on the Herschel machine are now awaiting their turn on the other machines to ascertain whether they will stand in the same qualitative order of sequence. A good degree of correlation has already been found between the results of static friction observations by W. C. Wilharm of the

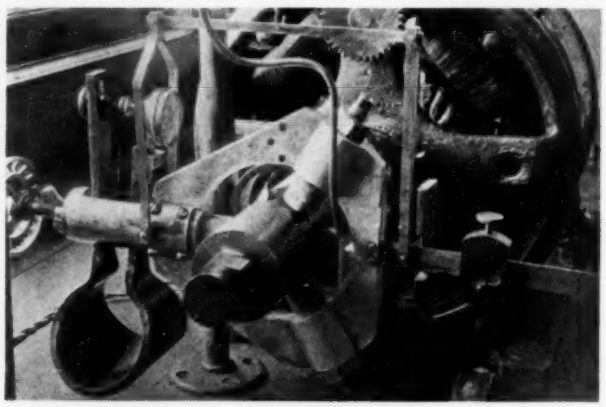

FIG. 3 DICKINSON GROOVED-CYLINDER MACHINE

Westinghouse Electric & Manufacturing Company and the results obtained by Mr. Herschel on the same lubricants, using the same pair of bearing metals (steel and brass).

G. H. S. Snyder has conducted a large number of experiments for the Committee on the Dickinson grooved-specimen machine at the Bureau of Standards, using brass, steel, and white-metal alloys for the bearing metals, in conjunction with lard oil, castor oil, high- and low-viscosity mineral oils, and oleic-acid mixtures. These observations have served to map out roughly the magnitudes of the friction values to be dealt with, and the degree of scattering to be expected upon repeating the tests using successive grooves. This machine was intended for seizure experiments rather than for oiliness measurements in the strict sense, and was designed primarily for testing cutting fluids under conditions of rapid abrasion. Three steel balls, or balls of any desired tool material, are forced against the rotating cylinder of work material in which grooves have already been machined with the same radius as that of the balls, while the load is read on a dial-indicator gage.

A study of conditions at the left of the minimum point (i.e., at low values of ZN/P) was undertaken for the Committee several years ago by C. W. Staples, using the Kingsbury oil-testing machine. This investigation was begun at the Carnegie Institute of Technology through the courtesy of Professor W. Trinks, and afterward repeated and continued at the Bureau of Standards.

In the original Pittsburgh experiments sperm, lard, mineral lard, heavy, medium, and very light mineral oils, and oleic-acid mixtures were tested in conjunction with brass bearing blocks and a steel journal. These bearing blocks were constructed, as in Mr. Kingsbury's tests (Ref. 11), with only a pair of narrow ridges on each block making actual contact on the journal. These ridges were well separated, in order, so far as possible, to prevent the usual tilting action of partial bearings from occurring, in the hope of avoiding the formation of any true fluid film. All this, of course, is for the purpose of eliminating viscosity effects and obtaining boundary lubrication alone, isolated from hydrodynamic action.

Bath lubrication was employed in order to control the temperature of the film and to standardize the amount of lubricant reaching the surfaces. Bearing pressures were brought up to the limit of the capacity of the machine, or about 10,000 lb. per sq. in. as a maximum. This resulted in a noticeable amount of wear, and a moderately wide scattering of observations.

The coefficients of friction, when plotted against ZN/P, showed a very wide divergence between the several oils. Now, if it were not for the existence of oiliness, i.e., some property of the lubricant which can influence friction, other than viscosity, all the curves would be expected to coincide (Ref. 22) provided the rate of wear is not too great. Accordingly, the differences between the ordinates of the curves can be taken as an indication of real differences of oiliness.

The curves for the heavy and medium mineral oils fall high up on the chart, while those for the fatty oils (lard, mineral lard, and sperm) fall considerably lower down, as might have been expected. A surprising fact was, however, that the curve for the very light mineral oil (a paraffin-base spindle oil) intersected the curves for the fatty oils at a sharp angle, so that over a limited range of ZN/P the oiliness of this mineral oil appeared to be superior to that of the fatty oils.

This anomalous result was the occasion for repeating the greater part of the work after a new machine of the same type had been constructed by Mr. Staples in Washington. The absolute values, to which little if any significance can be attached, differed considerably from those obtained in Pittsburgh. The relative positions of the curves for the respective oils were almost exactly repeated, including the anomalous intersection point.

One advantage of the Kingsbury machine over any type in which spherical or cylindrical contacts are employed is that the

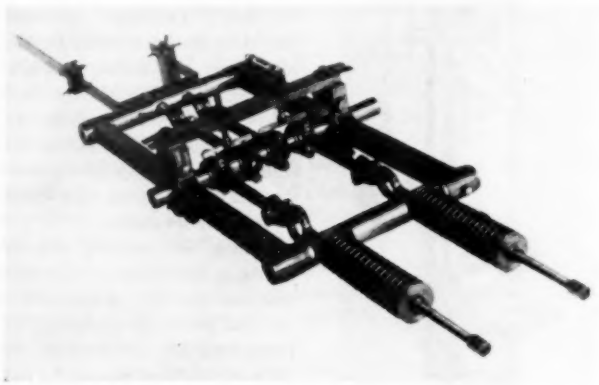

FIG. 4 MCKEE JOURNAL-BEARING MACHINE

total bearing area is a readily measured quantity unaffected by the elastic constants of the metal surfaces. Calculations of the effective film thickness can, therefore, be made, considering the viscosity in the film the same as that of the bath, and working back from the observed friction torque. From such calculations it appears that the film thickness under the heavier loads employed in the foregoing experiments was of the order of only one or at most a small number of molecular diameters.

While the McKee journal-bearing machine was not originally intended for oiliness measurements and requires a long period of careful running in before reproducible results are obtained, it has the advantage that the data will be obtained on actual bearings. The nature of the results that may be expected can be inferred from McKee's investigation of the effect of kerosene upon the oiliness of lubricating oils (Ref. 23) conducted with an earlier form of journal-bearing machine. Observations on the relative oiliness of a series of lubricants using the McKee machine with a set of well run-in white-metal bearings have recently been begun, for the purpose of a comparison with the other oiliness machines.

Another form of journal-bearing test, from which data may be obtained relating to oiliness and seizure, was described by H. C. Mougey in a recent paper (Ref. 57).

The Amsler machine which is in use at the Bureau of Standards for wear tests in connection with metallurgical investigations offers the possibility of oiliness measurements based on the frictional resistance of disks that are in contact circumferentially, and to which any desired differential motion can be given. It has been suggested that film formation might be successfully prevented by rotating the two disks in opposite directions. On account of the friction developed in the measuring mechanism itself, however, this machine is better suited for conditions under which the friction between the specimens is very high, rather than for tests in which the surfaces are to be preserved unchanged.

Another form of rotating-cylinder and stationary-specimen test, from which data may be obtained relating to oiliness and wear or "scuffing," was described by E. Wooler, Timken Roller Bearing Co., before the S.A.E. at Cleveland, November 17, 1930.

The inclined-plane apparatus will be held in reserve until further experience has been reported by the Westinghouse Electric & Manufacturing Company and the Bell Telephone Laboratories, Inc., both of whom are now investigating the problem of static friction measurement. It has been found that to obtain reproducible results requires an extreme degree of protection from vibrations.

With respect to the problem of ascertaining the minimum thickness of film below which the properties of a lubricant are no longer the same as in bulk, it has generally been considered for practical purposes that Albert Kingsbury's experiments with the tapered plug (Ref. 24) established a superior limit of 0.000025 in. The ordinary laws of motion of viscous fluids could therefore be relied upon down to films at least as thin as that amount.

From an investigation conducted by Ronald Bulkley at the Bureau of Standards and at Johns Hopkins University, it would appear that the limit has now been pushed down to, at most, no more than about one millionth of an inch (25$\mu\mu$). Dr. Bulkley's experiments were carried out on extremely fine capillaries of glass and of platinum in conjunction with mineral oil, oleic-acid mixtures, water, and other liquids of widely different chemical composition. The metal capillaries were skilfully drawn down to an internal diameter of about 0.0008 in. (200$\mu\mu$) and the glass capillaries to less than 0.0004 in. (100$\mu\mu$). The details of these experiments have been submitted for publication in the Bureau of Standards Journal of Research. It was concluded that no plastic adsorbed film could have been formed on the walls of the capillaries greater in thickness than the above stated limits without being detected in the course of these experiments as a departure from Poiseuille's law. Poiseuille's original experiments on the viscosity of water included measurements with glass capillaries down to 0.014 mm. (14μ) diameter without finding measurable effects that could be attributed to wall films.

As a preliminary step in the foregoing investigation it was necessary to check up very definitely on the curious phenomenon known as "clogging of capillaries" discovered by Wilson and Barnard in tubes as large as 0.3 mm. (over 1/100 in.), and attributed by them to the gradual building up of plastic adsorbed films of astonishing thickness. (See Ref. 25.) It may be concluded from Dr. Bulkley's experiments that the clogging effects previously mentioned were due solely to foreign particles such as lint and dust which could be eliminated by appropriate methods of filtering, and should not be attributed to the adsorption of any chemical constituent of the liquid.

Further evidence tending to disprove the supposed existence of extremely thick adsorbed films of a plastic consistency (Ref. 26) has recently been found by Ronald Bulkley and F. G. Bitner in connection with surface-tension measurements. (See Ref. 27.) In general, therefore, it appears that there is not so much valid experimental evidence in favor of extremely thick adsorbed films as was at one time assumed, and that the views of Langmuir (Ref. 28) and of Woog (Refs. 29, 30) to the effect that such films are generally monomolecular, or at most only a few molecules thick, are receiving important confirmation.

4 Other Investigations on the Program of the Committee. Professor Bradford at Pennsylvania State College has carried out a number of experiments in which careful measurements have been made of the total pressure on the bearing and the pressure values at different angular positions and has covered a range up to relatively high pressures as compared with standard bearing practice. This work it is expected will continue for at least another year.

A paper is in preparation by Mr. Karelitz entitled "The Oil Flow in a Perfectly Lubricated Bearing," which describes the results of experiments recently completed.

The investigation by Mr. Kingsbury designated as 4(*b*) in the above outline of the Committee's Experimental Program is reported in a paper being presented for discussion at this meeting under the title "On Problems in the Theory of Fluid-Film Lubrication, with an Experimental Method of Solution."

Status of Publications

Fourteen of the earlier publications no longer available have been selected for reprinting as Volume I of Collected Papers on Lubrication Research. The list includes Albert Kingsbury's papers on the friction of screws, on the experiments with an air-lubricated journal, on the new oil-testing machine, on the tests of large shaft bearings, and the first report of the Sub-Committee on Lubrication,[5] of which Mr. Kingsbury served for a long period as Chairman. (Refs. 10, 31, 11, 32, and 24, respectively.) It includes the paper by Professor A. W. Duff[6] on empirical formulas for viscosity as a function of temperature (Ref. 33), and two papers by Dr. A. E. Flowers, one on viscosity measurement and a new viscosimeter, the other on a cylinder friction and lubrication testing apparatus. (Refs. 34 and 35, respectively.) The remaining papers are by M. D. Hersey on the laws of lubrication of horizontal journal bearings (experimental), on the laws of lubrication of journal bearings (mathematical), and on the theory of the torsion and the rolling-ball viscosimeters and their use in measuring the effect of pressure on viscosity (Refs. 36, 22, and 4, respectively); by H. A. S. Howarth on slow-speed and other tests of Kingsbury thrust bearings (Ref. 37); by H. A. S. Howarth and N. Ogden on friction tests of propeller thrust bearings (Ref. 38); and by Commander L. J. Linsley, U. S. N., on the investigation of critical bearing pressures causing rupture in lubricating films (Ref. 39).

While no steps have been taken toward the publication of translated matter, a considerable number of the more recent French and German research papers have been translated and carefully edited, with photostats of illustrations, for the use of members of the Committee and contributors to the Lubrication Research Fund. For services in this connection acknowledgment is made to Winslow H. Herschel, Dr. Glenn F. Rouse, and Miss H. P. Bell.

Five articles dealing in some manner with the history and present status of lubrication research were prepared for publication in response to specific requests. (Refs. 13 and 40–43, incl.)

In connection with the proposed work on the elements of the mechanics and thermodynamics of lubrication, consideration has been given to questions of nomenclature, definitions, and units, and further applications have been made of the theory of dimen-

[5] The Special Research Committees of the Society were at that time designated as Sub-Committees of the Research Committee.

[6] Member of the committee until 1927 and adviser to the committee since that date.

sions, or dimensional analysis. (Refs. 44, 45.) The theory has been extended to include, as dependent variables (e.g., ordinates of a curve): the hydrostatic pressure in the film, the volume of oil flowing through a bearing due to its own pumping action, and the angle from the line of action of the load to any characteristic point of the film, such as the point of nearest approach and the points of maximum and minimum pressure; and as independent variables (e.g., abscissas of a curve): the inertia, compressibility, and capillarity of a lubricant; its pressure-coefficient of viscosity; gravity, as affecting delivery by oil rings or otherwise; and the static pressure of the oil supply in forced-lubrication systems. The use of the f vs. ZN/P diagram under oiliness conditions has been fully considered. In the extension of dimensional analysis to cover any of the foregoing practical conditions, including oiliness (except in the ideal limiting case where the effect of viscosity totally disappears) it is only necessary to introduce the appropriate additional dimensionless variables, without disturbing ZN/P or its equivalent. This variable, designated by the less convenient notation $\mu n/p$ in the earlier papers (Refs. 36, 22, and 46) can still be retained as the chief argument of a table or the base line of a diagram. As a further simplification the single letter g (for generalized variable) has been proposed in place of ZN/P, so that the customary method of plotting coefficient-of-friction observations can be designated more briefly as the "fg diagram."

A beginning has been made on the mathematical treatment of plastic lubricants, also on problems concerned with the rise of temperature in the oil film. A relation from which it appears, under certain conditions, that the excess of temperature in the oil film relative to the adjacent metal will be proportional to the square of the surface speed and independent of the film thickness was discussed at a meeting of the Committee in December, 1915, but not published. The same or an equivalent formula was independently discovered by Donald Bratt of the Brooklyn Edison Company (unpublished communication, 1927); and A. G. M. Michell (Ref. 47). A solution for the effect of a uniform change of temperature upon the coefficient of friction of a full journal bearing has been published to illustrate a new method of calculation that might be further applied. (Ref. 48, pp. 152–154.[7])

Eight papers on lubrication have been presented for discussion at the meetings of the Society, either by members of the Committee or upon the recommendation of the Committee, during the period elapsed since the publication of the last report, viz.: "Journal Running Positions," by H. A. S. Howarth (Ref. 49); "Friction of Journal Bearings as Influenced by Clearance and Length," by S. A. and T. R. McKee (Ref. 2); "Service Tests on Diesel-Engine Lubricating Oil," also "The Purification of Diesel-Engine Lubricating Oil," by A. E. Flowers and M. A. Dietrich (Refs. 50 and 51); "Grooving Bearings in Machines," also "Performance of Oil-Ring Bearings," by G. B. Karelitz (Refs. 52 and 53); "Progress in Fluid-Film Lubrication," by A. G. M. Michell (Ref. 47); and "A Study of Tin-Base Bearing Metals—II," by G. B. Karelitz and O. W. Ellis (Ref. 53).

Cooperation With Other Committees

The Special Research Committee on Lubrication cooperates with a number of other Committees working in closely related fields. At the present time contact is made with the Special Research Committee on Cutting of Metals through M. D. Hersey; with the Special Research Committee on Worm Gears through Earle Buckingham; with the Research Committee of the Society of Automotive Engineers through H. C. Dickinson; and with Committee D-2 of the American Society for Testing Materials, Petroleum Products and Methods of Testing, through A. E. Flowers, official representative of the A.S.M.E. on Committee D-2.

The following publications recently issued through the medium of various other Committees are of interest in connection with lubrication research: "Cooling and Lubrication of Cutting Tools" (Ref. 54); "Present Practice in the Use of Cutting Fluids," by S. A. McKee (Ref. 55); "Worm Gears—a Study and Review of Existing Data" (Ref. 56); "The Significant Properties of Automotive Lubricants," by H. C. Mougey (Ref. 57); "Progress on Efficiency Tests of Electric Street-Car Trucks," by S. A. McKee (Ref. 58); "Bearing Metals and Bearings," by W. M. Corse (Ref. 59).

Recent Foreign Investigations

At the time of the organization of our Committee 15 years ago the amount of activity in European countries in the field of experimental lubrication research was relatively insignificant. Today, the situation appears to be reversed. No one who has followed the work of such investigators as Hanocq in Belgium, Hardy and Stanton in England, Trillat and Woog in France, Kiesskalt and the Vieweg brothers in Germany, to name only a few, can fail to be impressed with the high standard of talent that is being concentrated upon lubrication problems, the extent to which such investigations are encouraged and promoted by the industries, the engineering societies, and the national government organizations, and the consequent rapid progress that is being made.

References 60–113, inc., will indicate the general character of the investigations in progress in European countries during the past three years. English, French, and German publications are separately grouped and arranged alphabetically by authors. The subject matter of the investigations listed herein includes hydrodynamic theory; the development of testing technique for friction and film thickness measurements; experiments on boundary lubrication, seizure, and high-temperature operation of bearings; and researches on oiliness (onctuosité, Schmierfähigkeit), including adsorption and molecular orientation.

Acknowledgments

Specific acknowledgments have been indicated wherever necessary in the foregoing pages. For cooperation in conducting the work leading up to this report a general acknowledgment is due to the U. S. Bureau of Standards and other organizations represented on the Committee, also to the numerous contributors to the Lubrication Research Fund; and to the Research Associates of this Committee in Washington, D. C., Miss H. P. Bell, Dr. Ronald Bulkley, and Messrs. T. R. McKee and G. H. S. Snyder.

Discussion

C. G. A. Schmidt, Jr.[13] In reading the paper, the writer fails to find any reference to research activities in connection with the lubrication of anti-friction bearings, and it seems that this phase of the question should receive careful consideration and investigation.

For the past three years this company has designed and marketed a series of roller-bearing rock crushers of the overhead eccentric-shaft type. This shaft operates the moving jaw. This jaw is mounted on the eccentric shaft with spherical roller bearings, and the shaft is supported in the crusher frame in spherical roller bearings. A machine of this type is subjected to unusually severe shock loads, practically of indeterminate quantity, subjecting the bearings to the most severe type of service.

Another serious phase is the presence of a great amount of gritty dust, naturally resulting from the crushing of stone, gravel, and similar materials. For this reason it has been considered the best practice to use grease as a lubricant rather than oil. Fresh grease can be pumped into the bearings every day, thereby forcing out the used grease with any gritty substance that may have accumulated at the outer ends of the bearings. The usual speed of these machines is approximately 300 revolutions per minute, and operating temperatures are expected not to exceed 100 to 125 deg.

The determination of the proper grease lubricants for use under such conditions should be a worthy contribution by your committee.

[12] See also Ref. 15.

[13] Chief Engineer, American Road Machinery Company, Kennett Square, Pa. Mem. A.S.M.E.

LOUIS ILLMER.[14] This report shows intensified activity on part of the Special Research Committee on Lubrication. It is noted that the so-called ZN/P relation is accepted as established and infallible. After carefully analyzing many authoritative friction tests (see "Friction Coefficient Research," S.A.E. Journal, June, 1930), the writer has been unable to find that such relationship does actually prevail as determined over wide-range operating conditions. The mere fact that a straight-line ZN/P plot may be obtained under certain working conditions affords no real proof that a more accurate basis for coordinating friction coefficients may not be afforded by a different and more comprehensive groundwork.

Other aspects of the present issue have been elaborated upon in the published discussion of the writer's paper. The accompanying curves clearly show the deviation from the ZN/P relation to become particularly marked, when the per cent of actual contact area is kept at a relatively low value. The net degree or effective contact ratio is a matter that apparently has been neglected by prior investigators.

It would appear, therefore, that the constancy of the alleged ZN/P ratio is taken too much for granted; possibly this is one reason for having to call upon the corrective "oiliness" function in order to reconcile the present findings. It might be expected, however, that the effect of oiliness should come into play only when the bearing load approaches the seizing pressure. The recent fashion of reporting experimental friction determinations in terms of the composite ZN/P relation alone is thought to be wholly unjustified from a scientific standpoint and makes the results practically useless for test-analysis purposes. It is the writer's opinion that the criticized ZN/P method has been made into a fetish and is unlikely to lead to a complete and satisfying solution of the friction-coefficient problem.

The writer has been unable to locate any reasonably simple and readily understandable treatment of the hydrodynamic theory of lubrication that convincingly proves up the expectation of the ZN/P relationship, especially one applicable to relatively low contact factors. As matters now stand, engineers are still unable to predetermine friction coefficient for many of their common but more-important operating conditions. Hence it may be expedient to wait with the further formulation of a complete theory of lubrication until the laboriously acquired experimental data of others have first been more thoroughly analyzed. A large and valuable mass of such work is already available, and it is not seen wherein continued experimentation without a more concrete objective will allow fully grasping the significance of past test findings.

There is apparently still need for new concepts regarding the inherently complex principles that underly friction behavior. In the present endeavor, it should clearly be kept in mind that the conventional coefficient is not a physical constant in a rational sense, but merely represents a convenient resultant measure of bearing efficiency. The factors that control such behavior center in a number of different variables, of which each such variable exerts an influence at its own distinctive rate, and these combine to produce a composite result. It is believed that after the effect of each such factor is more accurately known, a propitious time will have arrived for definitely formulating a theoretical basis for friction behavior that may or may not justify the use of the ZN/P relation.

R. MACDONALD.[15] The writer would draw the attention of this committee to the necessity of research on troublesome noise. He refers particularly to bearing noise, affected by lubrication.

Since the installation of motor appliances in offices, hospitals, apartments, and private homes, the demand for quiet operation has become more and more imperative. It has been found by experiment in the Westinghouse Laboratories that unnecessary noise may be prevented by lubrication.

There are many instances in industry where noise may be absorbed, and as there seems to be no precedent, much might be accomplished through research on this subject.

D. V. WATERS.[16] In view of the increasing use of anti-friction bearings in machine construction, some information relating to their lubrication is suggested as a fit subject for committee investigation. Some information in regard to the use of greases and blended oils also would be valuable.

Oiliness is defined as "the property which causes a difference in friction when two lubricants having the same viscosity at atmospheric pressure, and at the true temperature of the film, are tested under identical external conditions. The lubricant giving the lesser friction is then considered as possessing the greater oiliness." This is taken to mean, not that two oils, to be comparable in respect to oiliness, must have the same viscosity at the same temperature, but that to compare the oiliness of the two oils, the tests must be made at such temperatures as will make the viscosities the same. The present knowledge of this quality, what it is, how it should be measured and in what units, and what it means in regard to performance of lubricants, is not such as to make it of much immediate value from the practical standpoint, but oiliness research seems to promise considerable future help and should be followed rather closely by those interested in lubrication.

The reference to other research agencies, and especially the appended list of publications on the subject, should prove helpful to those studying the subject.

C. M. LARSON.[17] The question of evaluating film strengths has been one on which our company has been doing considerable research work. The film-strength testing machine (Fig. 5) and the following procedure are being used for testing various products.

The machine consists essentially of a steel pin A, which is turned by suitable means within three steel bushings at a constant speed, running in a bath of oil. There is a housing which acts as a support for the bushings and is substantial enough to keep them rigidly in absolute alignment, at the same time providing ample space for the lubricant being tested. This housing also bears projections for the purpose of providing a fulcrum pin upon which a substantial lever is rotatively mounted. This lever is provided with a counterweight and two poises so located that ratios of 40 to 1 and 10 to 1 may be obtained.

The pin A is exactly 1 in. in diameter and 3 in. long (1 in. by 3 in. ± 0.005), with a hexagonal head $^1/_2$ in. long to provide means for turning.

The bushings completely envelop the pin, the internal diameter being 1 in. plus 0.007 in. (1.007 in.) to allow ample space for viscous lubricants. The two end bushings are held rigidly in a suitable retainer, and the center bushing is held from turning in a suitable link, but is free to move vertically with the link which transmits the load from the lever to the pin.

Disks weighing 25 lb. each are provided, and when these are applied as at C, or upon the 40-to-1 poise, a load of 1000 lb. is imposed upon the projected area of the pin within the center

[14] Development Engineer, Brewer-Titchener Corporation, Cortland, N. Y. Mem. A.S.M.E.

[17] Supervising Enginer, Sinclair Refining Company, New York, N. Y. Mem. A.S.M.E.

bushing. (This is exactly 1 sq. in.) When the disks are applied as at *B*, or upon the 10-to-1 poise, a load of 250 lb. is imposed upon the same area.

The pin is driven through a flexible coupling link (located within the oil well to facilitate removal of pins) by means of a constant-speed motor and reduction gear at exactly 100 rev. per min. The motor must be of ample capacity so that no variation in speed occurs even though chattering starts, because it has been found that slight variations in speed under the predetermined rate result in actual seizure and damage to the machine.

A voltmeter and an ammeter are provided, and the variation in the current supplied indicates the performance.

The weights are applied one every 10 sec. until the oil film rup tures, which is indicated by the ammeter reading. At this point the load is removed with the motor still operating and the pin

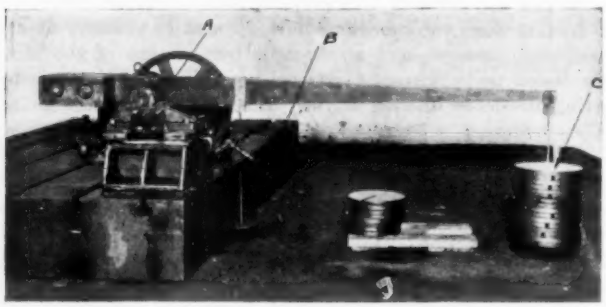

FIG. 5 FILM-STRENGTH TESTING MACHINE

turning, so that a true estimate may be made of performance by comparing the scratches (if any) which show upon the surfaces of the pins.

It is important to note that the 40-to-1-ratio poise is used when examining heavy viscous products such as gear lubricants, etc., and that a combination of the 40-to-1 and the 10-to-1 poises is used when examining oils of comparatively low viscosity. The results are plotted on cross-section paper, applied pressure versus meter reading in amperes.

This machine has the advantage of determining quickly the actual load in pounds per square inch that a lubricant may be expected to sustain without rupture, rapidly and with a minimum amount of oil.

It has been found that petroleum lubricating oils vary in film strength from 3000 lb. per sq. in. up to 12,000 lb. per sq. in. before seizure of the steel shafting and the steel bearing occurs. It also has been found that lubricating oils of the same viscosity made from different crudes have different film strengths. For instance, by taking three oils having a viscosity of S.A.E. 30, it will be found that a naphthene or Texas base oil has a film strength of around 3800 lb. per sq. in., a Mid-Continent 30 pour-point oil a film strength of about 4400 lb. per sq. in., whereas a Pennsylvania oil of 30 pour point has a film strength of approximately 4700 lb. per sq. in.

When the Mid-Continent oil is dewaxed to zero-pour, the film strength is raised to 5100 lb. per sq. in., whereas the Pennsylvania product when dewaxed has a film strength of 5800 lb. per sq. in.

By adding free fatty acid to an oil the film strength is raised approximately 5 per cent. It is possible to take an oil of 100 viscosity at 100 deg. fahr., which normally has a film strength of 3100 lb. per sq. in., and by adding 5 per cent of compound, to raise the film strength to 26,000 lb. per sq. in., and the viscosity of this blended product would not be more than 128 sec. at 100 deg. fahr.

High-film-strength lubricants are being developed for hypoid gears on rear axles, for roll necks, and for heavily loaded journals.

In testing used oils from automotive-engine crankcases, the film-strength testing machine shows definitely that the film strength decreases as the oil decomposes through oxidation and carbonization.

ALPHONSE A. ALDER.[18] The paper makes frequent reference to two physical properties, viscosity and oiliness. Since the terms used in this work will receive wide publicity and will find their way into future literature, the writer would like to suggest to the committee to give due thought to the choice of nomenclature. The well-known physical property of capillarity does not appear in the report. It is the writer's belief that this property is the basic property underlying both viscosity and oiliness. The wetting of surfaces by water, oils, etc., and the non-wetting phenomena of mercury on glass also can be explained by the property of capillarity.

If oiliness and viscosity are shrouded in mystery, research should be directed along these lines so that their phenomena may be coordinated properly with classical physics. The evident question to be answered is, What makes a substance a lubricant?

CLOSURE

The question of including the lubrication of ball and roller bearings within the scope of this Committee may be worthy of further consideration, as suggested both by Mr. Schmidt and by Mr. Waters, but has always hitherto been decided in the negative. The function of oil or grease in such bearings is not primarily one of lubrication, but rather for the purpose of protecting the surfaces and keeping foreign matter out of the bearings.

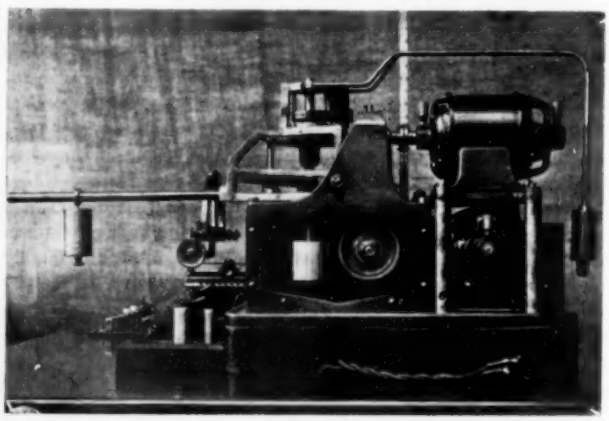

FIG. 6 VOITLÄNDER OILINESS MACHINE

From Mr. Illmer's discussion of the ZN/P diagram we are left in doubt whether he has thoroughly examined the original papers of 1914 and 1915 in which this method of analysis was first outlined. No claim has ever been made in publications of the A.S.M.E. Committee that the plot would necessarily be a straight line, but it is believed to offer a convenient method for separating the effects of viscosity from the unknown factors that remain to be investigated.

The determination of critical loads at which seizure occurs, as described by Mr. Larson, has much in common with the procedure described by H. C. Mougey of the General Motors Research Corporation, for seizure tests on automobile rear-axle differential pins (Ref. 57).

The investigation of conditions at seizure was the purpose in

[18] Consulting Engineer, New York, N. Y. Mem. A.S.M.E.

mind in the Dickinson machine as described by C. F. Marvin, Jr. (Ref. 16). All such methods are of great interest. The Committee hopes to ascertain whether any correlation exists between the critical loads so determined, and the solidifying pressure determined hydrostatically, as stated in Table 2 of the present report.

The Committee is indebted to Dr. Rolf Voitländer of the Hydraulisches Institut Technische Hochschule, Munich, for sending a brief description and a photograph, reproduced herewith as Fig. 6, of his improved form of oil-testing apparatus, developed as a continuation of his previous investigation (see Ref. 108). This apparatus will be fully described in the next "Mitteilungen des Hydraulischen Instituts der Technischen Hochschule," München, Heft 4, which is to appear shortly. The previously published work dealt with a comparison of different oils using a given combination of bearing metals. The more recent work with the newest apparatus, as conducted by W. Bürner and reported by Dr. Voitländer, includes also an intercomparison of bearing metals, and very satisfactory results are reported as being obtained.

PME-53-5

Repairing Oil Trunk Lines by Arc Welding

By ALBERT N. HORNE,[1] BARTLESVILLE, OKLA.

Repairs to oil trunk lines should be made in the field without interruption to the service, and the methods of fixing up split joints, leaking couplings, and line breaks by the use of arc welding are described. Pipe line that has been corroded or that has become badly pitted also is patched and repaired by this means. Data are given to show that patch welding pays.

OIL TRUNK LINES are usually operated very nearly continuously and at such capacity factor or on such time schedule that any interruption of service is detrimental to efficiency and may mean loss of revenue. If the interruption is a line break or leak, considerable loss of oil and attendant damages may result therefrom. In years past the general practice in the oil industry has been to have large storage-tank "farms" in the field, along trunk lines, and at the refineries. This system was the result of a policy of getting the oil out of the ground as quickly as possible when a productive area was found and of storing it as a reserve over periods of lean production if the immediate supply were greater than current demand. Storage along a trunk line was partly with the idea of having an intermediate buffer to take care of oil movements in case of line outage. Each trunk-line pump station was equipped with considerable storage for the same purpose, and also to provide two or more working tanks in order to enable a check on receipts and pumpings over each section of line between stations. By receiving the oil in one tank and pumping it out of another tank, losses or shortages were quickly detected and leaks or line breaks more readily located.

Modern methods are tending to place the location and production of crude oil on such a basis of certainty that the storage of large volumes of crude for reserves is not warranted, and modern trunk lines are so constructed that the hazards of operation, such as outages due to split joints, leaking couplings, and line breaks, are practically eliminated. Protection of underground lines against the ravages of corrosion has progressed remarkably in the last few years.

These factors, together with possibilities of unit production of crude, are causing a definite trend toward smaller storage-tank farms. The development of centrifugal pumping equipment makes possible the total elimination of tankage at relay pump stations. Thus the trunk line itself must more nearly than ever operate close to 100 per cent as to capacity and time factors.

These conditions therefore have caused the development of more efficient methods of making emergency repairs and of reconditioning the older lines without taking them out of service for any lengthy period of time.

On the old screw-coupled line the method of repairing a break or a split was to cut out a section of the pipe with pipe cutters, rethread with hand dies, and then couple up with a companion flange. The smaller pit holes were repaired with saddle clamps, and leaky couplings were calked or collar clamps were applied.

With increasing use of welding in pipe-line construction, breaks are repaired by draining the line, cutting out the section, plugging the open ends of the pipe by tamping full of mud to hold back the oil and vapors, and then welding in a section of pipe. On a screw-coupled line this method is probably no more rapid than the screw-flange method, due to having to wait some time under certain conditions to drain the line sufficiently to prevent blowing the mud plug, but it does permit of making the repair with a lesser number of men, as only a bell-hole for the welder is required, whereas to screw-couple it requires that considerable line be stripped and raised from the ditch to facilitate flange-coupling.

In order to keep oil moving through the line continuously and at the same time to recondition a stretch of line economically, both in summer and in winter, the arc-welding machine has been successfully put to use.

A typical method, on an 8-in. loaded line, is to uncover the pipe, raise it from the ditch and place it on skids over the ditch, and then run a traveling cleaning machine over it. The pipe is then carefully inspected, and all serious pit holes, defective couplings, and badly corroded areas are marked with chalk.

A gasoline-engine-driven arc-welding machine mounted on wheels is then pulled alongside the line where the repairs are to be made. The machine is equipped with a long cable so as to work upon as much pipe as possible at one set-up. The metal electrodes are ordinary mild-steel general-purpose rods, from $^3/_{32}$ to $^3/_{16}$ in. in diameter and 14 in. long.

Where the pits are not too deep or too numerous, the repair is made simply by filling the depressions with the arc-weld deposit. On a line under pressure, a rough estimate for safety is a pit that is very little more than half through the pipe wall and not over $1^1/_2$ in. in diameter. No special cleaning of the pit is necessary nor is any special technique required for welding. The striking of the arc expels with explosive force the small amount of oxides and corrosion deposit, and this same material seems to act in the capacity of a flux. The bond is always good, as evidenced by numerous specimens cut out, cross-sectioned, and carefully examined. The actual welding time of the average pit, up to $^1/_2$ in. in diameter, is 15 to 30 sec.

In nearly four years' continuous recondition by one gang, with two welding machines, only two or three "burn throughs" on loaded lines have occurred, and these were not serious.

If the pits are nearly through the pipe wall or are grouped so closely that individual fills are not economical, the next step in the operation is to apply a patch or "half sole."

This patch is made by cutting with the oxyacetylene torch a piece of the desired length and width from the same size of pipe as that under repair. The patch is then placed on a joint of pipe and hammered with a few sledge blows, which shape it

---

[1] General Superintendent, Empire Pipeline Company. Mem. A.S.M.E. Mr. Horne was born Nov. 4, 1894, in Mississippi. He worked in the yellow-pine lumber districts between schooling, in sawmills, planing mills, log camps, office, commissary, etc. He is a graduate of Mississippi A. and M. College, B.S.E.E., 1917. He was with the Tank Corps, U. S. Army, 1918; student engineer with the Empire Companies in 1919 and in various capacities until 1928; General Superintendent of the Empire Pipeline Company since 1928. Mr. Horne is on the A.S.M.E. Research Committee on Automatic Pump Stations and a member of the Reserve Officers Association of the United States and Captain, Infantry Reserve.

Presented at the First National Petroleum Meeting, Bartlesville, Okla., Oct. 6–8, 1930, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

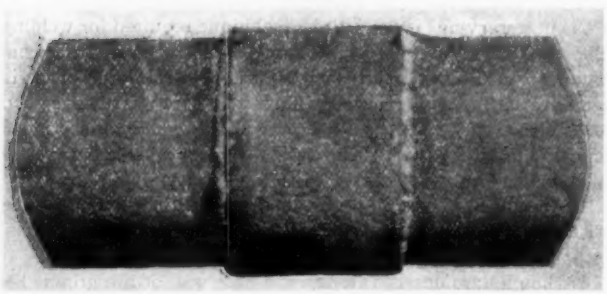

FIG. 8 COLLAR "ROPED" BY ARC-WELDING

nearly enough to the outside diameter on which it is to be applied. A good source of supply is straight junk pipe which may be badly corroded on only one side. For an extended job of reconditioning, patches are cut at one central point in lengths of 6, 5, 4, 3, 2, 1, and $^1/_2$ ft., then distributed to the welding machines.

A patch is clamped in place over a badly corroded area, usually the bottom side of the pipe, and is tacked and then welded to the pipe with one heavy bead. No special cleaning or grinding is necessary on this, and these patches have been subjected directly to pressures far exceeding operating pressures, without failure. It is sometimes necessary to patch the full length of a joint, or even several in succession. This is done by joining up the required lengths of patches.

In some instances, such as creek crossings or areas where the pitting or corrosion covers the entire pipe area, it has been necessary to encase one or more joints entirely. This is done by splitting a joint of 10-in. pipe, then placing it over the pipe, the seams being welded and the ends swaged down and welded to the line.

Leaky couplings that can be calked dry or couplings that appear to be weak due to threads not being run up fully are "roped," by welding each end of the coupling to the pipe. This method does not weaken the joint. Several full-joint roped couplings and one regular screw coupling properly set up were shipped to one of the pipe mills for pull tests, and results show that the roping added considerably to the strength of the screw coupling.

If the coupling cannot be calked dry or is corroded excessively, the repair is made by applying a special split sleeve designed for the purpose. This sleeve is the equivalent of a double-end swage, split in half, with a recess fitting fairly snugly over the coupling and of sufficient length to enclose any exposed threads. The two halves are clamped in place, the seams are welded, and then the ends are welded to the pipe.

These couplings have been directly subjected to over 2000 lb. pressure without failure, and bend and pull tests were entirely satisfactory.

These same split sleeves are being used instead of straps to reinforce welded joints on river crossings. They are welded in place, and the recess or annular space is filled with molten lead through holes cut for the purpose.

Emergency repairs are being made on operating lines by arc-welding patches over holes in place of saddle clamps, and methods are being worked out to repair sizable collar leaks, splits, and cracked or broken welds. Arc-welding machines for emergency-repair gangs are being mounted on regular maintenance-gang trucks and are driven from the truck motor. Machines are on the market which have take-offs for lights and for operating cleaning brushes and grinding wheels.

The economic limit of repairing a line by the various patch methods in the worst places is a cost per foot equal to the cost per foot of cutting out and replacing with new pipe. If continuous operation of a line is a factor, this limit may be exceeded, within reason.

Accurate cost data on recondition work have been kept, and results show that patch welding pays.

A section of 8384 feet of pipe in very bad condition may be cited to give an idea of costs, the repairs being summarized as follows:

Sleeves	23
Feet of weld bead for sleeves	165
Collars roped	72
Feet of weld bead for collars	324
Pits filled, feet of weld bead	168
Patches, square feet	5275
Feet of weld bead for patches	2105
Casing, 10-in., lineal feet	80
Lineal feet 8-in. line reconditioned	8384
Labor	$ 712.26
Material	767.20
Equipment, operation, depreciation, etc	352.75
Total	$1832.21
Cost per lineal foot	$0.2185

PME-53-6a

Evaluation of Steam-Turbine Oil Stability

By C. M. LARSON,[1] NEW YORK, N. Y.

The Navy work-factor method, although sufficient in itself to indicate the rate of decomposition, loss through evaporation, and the corrosive tendencies in steam-turbine oils, fails to measure definitely the resistance to emulsion. Considering demulsibility at 130 deg. fahr. of samples taken every 25 hr. during the 100-hr. Navy work-factor run, however, the emulsion tendencies are recorded, and this demulsibility change is a measure of the stability of steam-turbine oils.

IT IS a well-known fact that various turbine oils in the presence of different combinations of heat, air, and water deteriorate at varying rates. The usual measure of stability is determined by four things: (1) How fast the turbine oil decomposes, (2) resistance to emulsion, (3) loss through evaporation, and (4) whether the oil becomes corrosive. The practical test by placing the oils in the steam turbine and recording the changes in characteristics or analyses, as shown in Fig. 1, is tedious work. It takes months to evaluate turbine oils in actual service. Then, too, due to the variation in conditions under which turbines are operated, it never has been possible to make a direct comparison of the sludge and emulsion percentage increases between two oils while in service or even two lots of the same oil.

In order to simplify the procedure and have a compact test for steam-turbine oils, a Navy work-factor machine, Fig. 2, was built, the work-factor evaluation method being required for Navy approval of lubricating oils when bidding on U.S. Navy contracts. This machine has been used very successfully for evaluating lubricating oils. However, for turbine oils, Navy grading by the formulas, Table 1, did not seem complete, so that a scheme of including the demulsibility at 130 deg. fahr. (Method 320.31, Technical Paper 323-B) on the oil when new, the 25-hr., 50-hr., 75-hr., and 100-hr. periods was added. The constants of the machine are as follows:

Motor speed	3500 r.p.m.
Gear-reducer ratio	1.75 to 1
Journal speed	2000 r.p.m.
Journal diameter (D)	3.82 in.
Journal circumference	12 in.
Bearing length (L)	6 in.
Bearing chord (effective, C)	3.5 in.
Projected area (effective)	21 sq. in.
Load per sq. in.	150 lb.
Quantity of oil for test	5 quarts
Oil pump delivery	1.5 g.p.m.
Oil pressure to bearing (P)	15 lb. per sq. in.
Length of run (continuous)	100 hr.

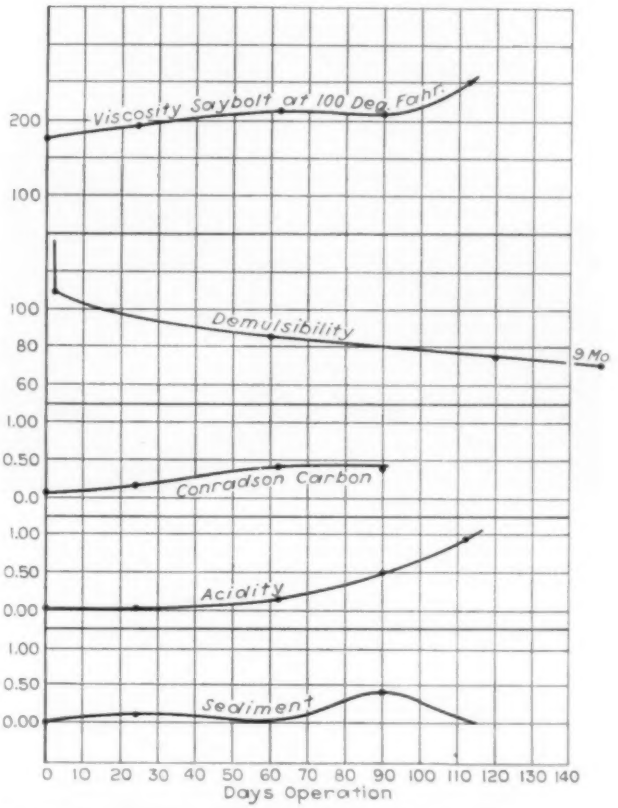

FIG. 1 CHANGE OF CHARACTERISTICS OF TURBINE OIL USED IN 10,000-KVA. STEAM TURBINE

TABLE 1 NAVY ENDURANCE TEST WORK-VALUE FORMULAS

Formula No.	Symbol	General formula	Turbine oils Formula for oils 2110-2190
1	V'_1	$1.00 - \frac{S_f - S_0}{S_0} \times \frac{1}{C}$	$1.00 - \frac{S_f - S_0}{S_0} \times 5$
	V'_1	At 100 deg. fahr.	Work value based on Saybolt viscosity
	V''_1	At 130 deg. fahr.	Use same formula as for V'_1
	$V''_1{}'$	At 210 deg. fahr.	Use same formula as for V'_1
	V_1	$\frac{V'_1{}' + V''_1 + V''_1{}'}{3}$	Average viscosity work value
2	V_2	$\frac{R_0 - C_0}{R_0}$	$\frac{0.55 - C_0}{0.55}$
3	V_3	$\frac{R_f - C_f}{R_f - C_0}$	$\frac{1.05 - C_f}{1.05 - C_0}$
	V_{23}	$\frac{V_2 + V_3}{2}$	Average Conradson carbon work value
4	V'_4	$\frac{R_f - C_f}{R_f - C_0}$	$\frac{1.01 - C_f}{1.01 - C_0}$
	V'_4		Neutralization work value
4	V''_4	$\frac{R_f - C_f}{R_f - C_0}$	$\frac{1.01 - C_f}{1.01 - C_0}$
	V''_4		Precipitation work value
	V_a	$\frac{V_1 + V_{23} + V'_4 + V''_4}{4}$	Average work value

Legend:
S_0 = Initial Saybolt viscosity
S_f = Final Saybolt viscosity
R_0 = Initial rejection point
R_f = Final rejection point

By referring to Fig. 3 it will be noted that there are plotted the neutralization numbers of the oil when new and at the end of the 100-hr. Navy work-factor run. These are the numbers that enter into the work-factor evaluation. The lower set of curves are those plotted from the demulsibility numbers determined from the 25-hr. period samples of the same oils whose neutralization numbers are plotted in the top set of curves. In general there is some similarity in decomposition of the oils as based on the neutralization numbers and judged by the demulsibility changes. That is, oils 1 and 5 that have the greatest increase in acidity fall off the most in demulsibility, whereas oils 2, 3, and 4 are the reverse. However, when oils 2 and 3 are

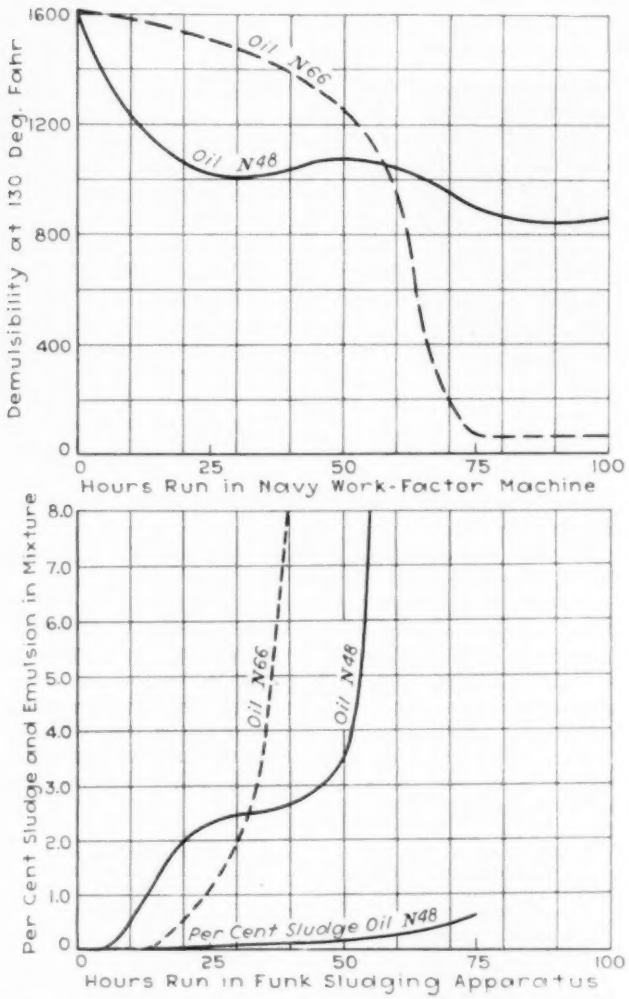

FIG. 4 RESULTS OF TEST OF OILS N-48 AND N-66 IN FUNK SLUDGING-TEST APPARATUS AND NAVY WORK-FACTOR MACHINE

classified by the demulsibility determined by the 25-hr. samples, oil 2 appears to be better than 3 throughout the entire 100-hr. range, and yet making a comparison of the two oils based on the neutralization numbers alone, 3 is better than 2. The same variations are shown by oils 1 and 5.

Now, by studying two turbine oils of exactly the same source and produced under the same refinery methods, with the exception of a slightly different degree of filtration, the value of using the demulsibility determinations of the 25-hr. period samples in addition to the work-factor numbers can be seen. The analyses

of the new oil and 100-hr. period samples, the Navy work values, and the demulsibility determinations are given in Tables 2 and 3.

Under the Navy work-factor method of evaluation turbine oil N-48 would be classed as having a value of 0.944 (considering the acid number separately 0.972), whereas turbine oil N-66 has a higher work evaluation of 0.974 and an acid number rating of 0.986; so that by work-factor evaluation, turbine oil N-66 is a superior product to oil N-48. However, by determining the demulsibility numbers of the 25-hr. period samples, Tables 2 and 3, N-48 is shown to be superior to turbine oil N-66.

Further to prove the superiority of turbine oil N-48 over N-66, the two oils were checked in the Funk sludging-test apparatus. The results of both the demulsibility numbers and the Funk sludging test proved that turbine oil N-48 outranked N-66, as shown in Fig. 4.

From the foregoing it is rightly concluded that the Navy work-factor method, although sufficient in itself to indicate the rate of decomposition, loss through evaporation, and the corrosive tendencies in steam-turbine oil, fails to measure definitely the resistance to emulsion. By taking into consideration the demulsibility at 130 deg. fahr. of samples taken every 25 hr. during the 100-hr. Navy work-factor run, the emulsion tendencies can be recorded as well, and this demulsibility change is a real measure of the stability of steam-turbine oil.

Discussion

M. A. DIETRICH.[2] In using the increase in neutralization numbers of oils as measures of rates of deterioration, useful information is frequently obtained by determining how much of this acidity is water-soluble. Even though an oil may have a high acidity it does not necessarily follow that the oil is corrosive. The nature of the acidity is important.

PME-53-6b

The Work Factor of Lubricating Oil

By JAMES G. O'NEILL,[1] ANNAPOLIS, MD.

The usefulness of the standard laboratory tests in judging the quality of lubricating oils in the past has been limited, due to widely different crudes from which lubricating oils are produced and to the varied processes used in their refinement. The new method proposed for evaluating lubricating oils seeks to extend the application of the standard laboratory tests in that their results will indicate the service that will be obtained from the oils in actual operation. Increases in viscosity, neutralization number, precipitation number, and per cent of carbon residue of a lubricating oil when subjected to an endurance test, which simulates service conditions as found in a forced-feed lubrication system, are expressed numerically by means of formulas, and the average of these results is called the work factor of the oil. A description of the method and apparatus of the endurance test is given, and the concordance of results obtained is shown when different machines are used to test the same oil. The work factors of turbine, Diesel-engine, and aviation oils are discussed with relation to their performance in actual service. The Navy method for purchase of lubricating oils employing the work factor is discussed, as also are the advantages derived from the use of the work factor.

LUBRICATING OILS for turbines, Diesel engines, and aviation engines may show by the standard tests to have properties that are in accordance with oils that are known to be satisfactory, yet they may be very unsuitable. Specifications for lubricating oils embodying the standard tests are of value when they cover a narrow range of oils made from a crude and by processes of refinement which are known to yield satisfactory oils, but when such specifications are used for oils made from widely different crudes or by widely different methods of refinement, their value is very doubtful. Lubricating oils, when obtained from various refiners having different crudes or different process of refinement, must, in order to insure safe and economical operation of machinery, be subjected to some test which will give true information of their suitability and the quality of the service to be obtained from them; in other words, the test must tell whether or not an oil is satisfactory for use and also properly evaluate satisfactory oils, in order that the consumer may be able to decide what oils are the most economical to purchase.

The suitability and evaluation of lubricating oils are believed to be very well accomplished by means of the work-factor evaluation method. This method is the result of the accumulation of information over a long period of time of the behavior of oils in service and their behavior when subjected to an endurance test which simulates service conditions. In reality it is an accelerated service test for lubricating oils carried out in a rugged machine, equipped with a test journal, which operates at a fixed speed and bearing pressure continuously for 100 hours without means for heating or cooling the oil. It is not the purpose of the endurance test to replace the standard tests for lubricants, but rather to increase the usefulness of these tests in determining the suitability of lubricating oils and in evaluating them.

Apparatus and Method of Test

The apparatus, as shown in Figs. 1, 2, 3, and 4, consists of a machine steel journal *K* 6 in. long and 3.82 in. in diameter, which revolves in a split babbitt-metal bearing, the lower half of which is embedded in the base *A* and the upper half in the bearing cap *U*. The journal is directly connected to a flexible coupling *L* on the shaft of a $3^1/_2$-hp. motor *M*. The bearing pressure is applied to the bearing cap by means of four calibrated springs *D*. The revolutions of the journal are obtained from revolution counter *J*. The bearing cap is fitted with a pressure gage *H* and a mercury glass thermometer *F* for the purpose of ascertaining the oil-film pressure and the temperature of the bearing. The temperature of the oil to the bearing is obtained from mercury glass thermometer *E* inserted in a thermometer well in the inlet oil line *V* to the bearing. The oil to the bearing is supplied from the oil reservoir in the base *A* through the pump *O*. The oil reservoir is equipped with a gage glass *B*, filling connection *C*, and a drain plug *P*, in the oil line *R*. The driving motor *M* is calibrated and equipped with voltmeter and ammeter.

Five quarts of the oil to be tested are poured in the oil reservoir, through the filling connection. The oil is pumped from the reservoir to the oil groove in the bearing. The journal is then started, and the bearing pressure is equally and gradually applied by the springs until the nominal pressure of 150 lb. per sq. in. is obtained, when the speed of the journal is raised to 2000 r.p.m. The test is then started and run continuously for 100 hr., during which time hourly readings are taken of all the instruments. During the test all oils of the ultra-heavy grade (S.U.V. at 130 deg. fahr. 300–340) and heavier are fed at a pressure of 15 lb. and lighter oils at a pressure of 10 lb. During the test the leakage loss of oil amounts to about 5.0 per cent, which leaves sufficient oil for the test. It is essential that no new oil be added during the test. The oil is examined before and after the test in order to determine the nature and extent of the changes in the oil during the test.

Work Factor

The foregoing test was developed in 1920, some of the results obtained being published in 1921.[2] Since that time a large

[1] Chief Chemist, United States Naval Engineering Experiment Station, Annapolis, Md., and technical adviser to the Bureau of Engineering, Navy Department, Washington, D. C., on lubrication. Mr. O'Neill was graduated from Cornell University in 1903. He has been associated as chemist with the Carborundum Company, the Cayuga Lake Cement Company, the Empire Coke Company, and the Semet-Solvay Company. He was the first to devise and operate a successful liquid purification process for coal gas, the description of the process being presented to the Eighth International Congress of Applied Chemistry.

Contributed by the Petroleum Division and presented at the Annual Meeting, New York, N. Y., Dec. 1 to 5, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] "Endurance Test of Force Feed Oils," by J. G. O'Neill, Associate, Journal of the American Society of Naval Engineers, vol. 33, no. 2, May, 1921.

number of tests have been conducted on oils using this method. The results of these tests have been used in determining the suitability of oils for naval use. All oils showing abnormal

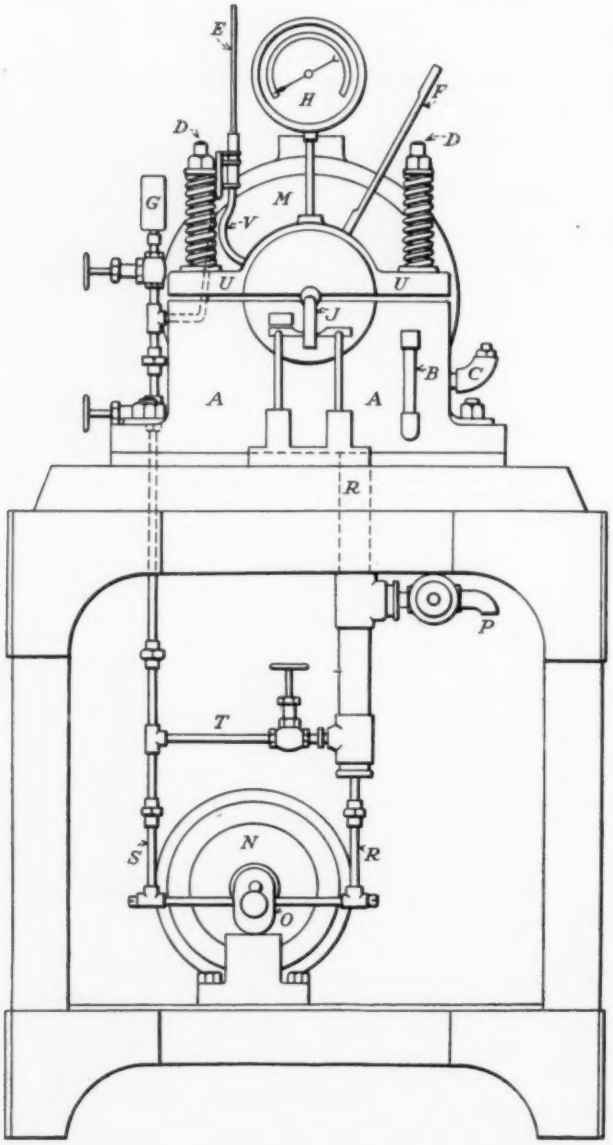

FIG. 1 DIAGRAM OF FRONT VIEW OF ENDURANCE OIL-TESTING MACHINE

increases, when subjected to the test, in viscosity, acidity, asphaltic matter, and carbon residue, were rejected. These tests showed that acceptable oils did not increase beyond the following limits in these properties, when subjected to the test:

Viscosity	All oils below aviation oils in viscosity, per cent	20
	Aviation oils, per cent	25
Neutralization number		1.01
Precipitation number		1.01
Carbon residue, per cent	Oils of viscosity 190 sec. at 130 deg. fahr. and below	1.05
	Oils of viscosity 190 to 340 sec. at 130 deg. fahr.	2.05
	Aviation oils	3.05

In 1928, Keleher and McGeary[3] proposed a work-factor method of evaluating lubricating oil for forced-feed and motor-cylinder use, based upon the oil's behavior in the endurance test as regards increases in viscosity, neutralization number, precipitation number, and per cent of carbon residue. Since the publication of this article, slight changes have been made in the method of calculation of the work factor, and it is considered advisable to give a brief description of the method. Table 1 gives the Navy's classification of the oils, and Table 2 gives the limitations of the necessary characteristics for determining the work factor of these oils.

TABLE 1 U. S. NAVY CLASSIFICATION OF OILS

Navy symbol	Commercial designation	Viscosity at 130 deg. fahr.	S.U.V. at 210 deg. fahr.
1075	Refrigeration oil	65–85	.....
2110	Light forced-feed and motor-cylinder oil	100–115	.....
2135	Medium forced-feed and motor-cylinder oil	125–145	.....
2190	Heavy forced-feed and motor-cylinder oil	180–200	.....
2250	Extra-heavy forced-feed and motor-cylinder oil	240–260	.....
2310	Ultra-heavy forced-feed and motor-cylinder oil	300–340	.....
3080	Winter aviation oil	.....	75–85
3100	Summer aviation oil	.....	90–100
3120	Heavy aviation oil	.....	115–125

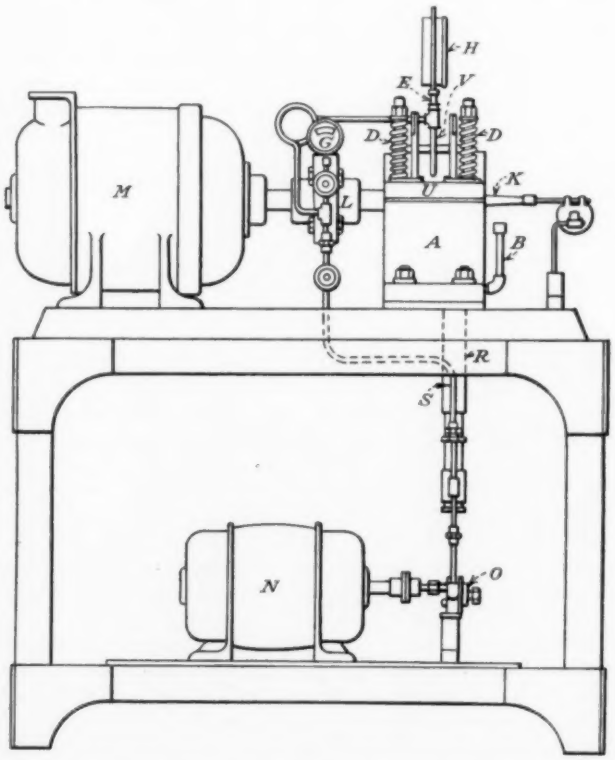

FIG. 2 DIAGRAM OF SIDE VIEW OF ENDURANCE OIL-TESTING MACHINE

The viscosities of the new and used oils are taken at three temperatures, 100, 130, and 210 deg. fahr., and the work value for the oil at each of the temperatures is calculated; the average of the three work values is the viscosity work value.

The formula used for oils 1075 to 2310, inclusive, is as follows:

$$\text{Work value} = 1.00 - \frac{\text{Final viscosity} - \text{initial viscosity}}{\text{Initial viscosity}} \times 5$$

The formula used for oils 3080 to 3120, inclusive, is:

$$\text{Work value} = 1.00 - \frac{\text{Final viscosity} - \text{initial viscosity}}{\text{Initial viscosity}} \times 4$$

[3] "How the Navy Selects Its Lubricants," by Com. T. J. Keleher, U.S.N., and F. M. McGeary, *Manufacturing Industries*, August, 1928.

The neutralization number and precipitation number work values are each determined by the following formula:

$$\text{Work value} = \frac{\text{Final rejection point} - \text{Final content or content of used oil}}{\text{Final rejection point} - \text{Initial content or content of new oil}}$$

TABLE 2 LIMITING VALUES FOR WORK-FACTOR DETERMINATION

		Unused oil; initial rejection point	Used oil after endurance test; final rejection point
S.U.V. viscosities at 100, 130, and 210 deg. fahr. of oils 1075 to 2310, incl.		..	In excess of 20% increase
S.U.V. viscosities at 100, 130, and 210 deg. fahr. of oils 3080 to 3120, incl.		..	In excess of 25% increase
Neutralization number		0.11	1.01
Precipitation number		0.05	1.01
Carbon residue, per cent	Oils 1075 to 2190, incl.	0.55	1.05
	Oils 2250 and 2310	1.05	2.05
	Oils 3080 to 3120, incl.	1.55	3.05

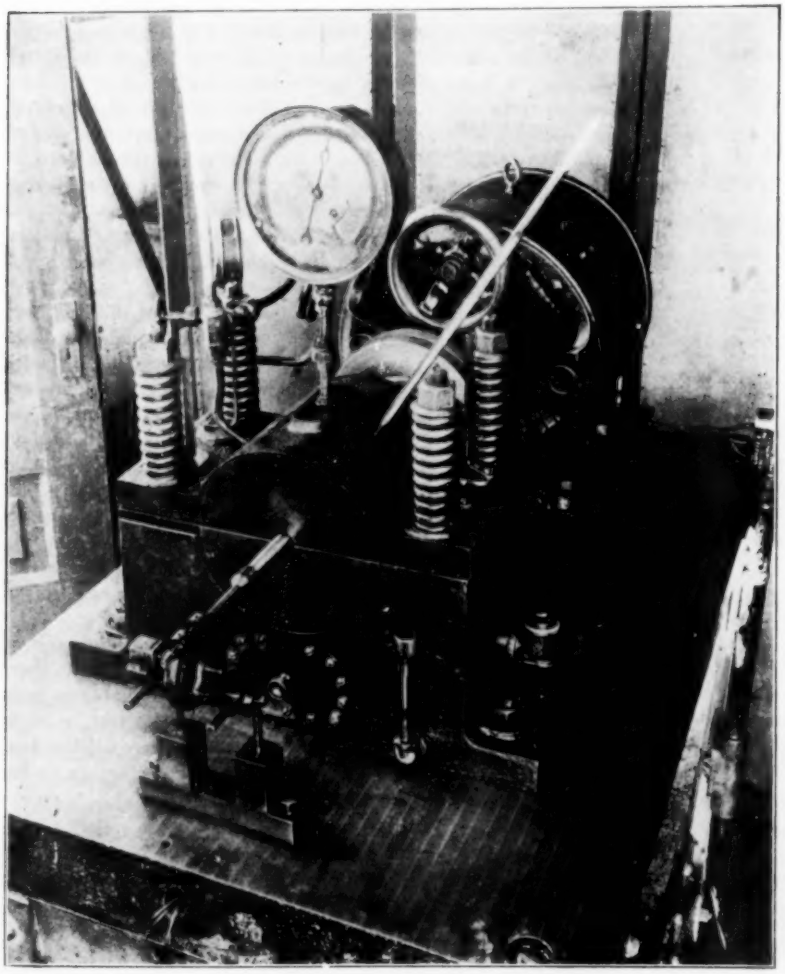

FIG. 3 PHOTOGRAPH OF FRONT VIEW OF ENDURANCE OIL-TESTING MACHINE

The carbon residue work value is calculated from two formulas—one used for the oil when new and the other for the oil after the test; the average of the two being the carbon residue work value.

The formulas are as follows:

$$\text{Work value for new oil} = \frac{\text{Initial rejection point} - \text{Initial content}}{\text{Initial rejection point}}$$

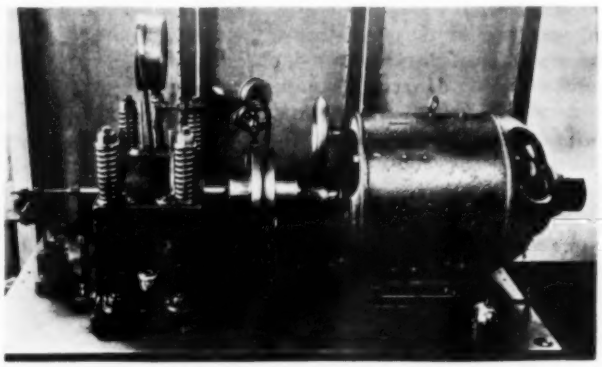

FIG. 4 PHOTOGRAPH OF SIDE VIEW OF ENDURANCE OIL-TESTING MACHINE

$$\text{Work value for used oil} = \frac{\text{Final rejection point} - \text{Final content}}{\text{Final rejection point} - \text{Initial content}}$$

To obtain the average work value of the oil the foregoing results are assembled and expressed as follows:

Work-value viscosity at 100 deg. fahr. ....
Work-value viscosity at 130 deg. fahr. ....
Work-value viscosity at 210 deg. fahr. ....

(*A*) Viscosity work value = $\frac{\text{Total of above work values}}{3}$

(*B*) Neutralization number, work value ....
(*C*) Precipitation number, work value ....
Work value, carbon residue, new oil ....
Work value, carbon residue, used oil ....

(*D*) Carbon residue, work value = $\frac{\text{New and used oil, work values}}{2}$

Total (*A*), (*B*), (*C*), and (*D*) ....

Average work factor of oil = $\frac{\text{Total of work values}}{4}$

The highest work factor possible for an oil is 1.00. Where any of the foregoing work values is less than zero, a zero rating is given. An oil having an average work factor less than 0.50 is not considered suitable for use, nor is any oil which, when subjected to the test, exceeds any of the rejection points shown in Table 2.

CONDITIONS AFFECTING WORK-FACTOR DETERMINATION

In a previous paper,[4] there were discussed the work factors of lubricating oils made from different crudes, the lack of tempera-

[4] "Evaluation of Lubricating Oil by the Work Factor Method," by J. G. O'Neill and F. M. McGeary, *National Petroleum News*, June 11, 1930.

ture control, reproducibility of results on different machines, and the consumption of lubricating oils in service which have different work factors. Since this was published a lubricating oil was subjected to endurance tests in four different machines, all operating at the same time. The work factor for the oil from each machine was determined, and it was found that the results from all four machines varied less than 5 per cent. These tests were run during a hot summer month. Previously, the work factor of the same oil had been determined during a cool fall month. It was found that the average work factor for the four runs during the summertime was 0.73 per cent greater than the work factor of the oil as determined in the fall month. Table 3 gives the results of the endurance tests of the oils, and in Table 4 are shown the calculated work factors of the oils and their properties after being subjected to the endurance test.

In order to apply the bearing pressure, no clearance can be allowed between the test journal and the bearing. Therefore, the metals of the two members are separated during operation only by the thickness of the oil film. This means that the bearing must be in good condition and run in by means of bearing grinding compound. Immediate seizing will take place between the journal and bearing if the oil pressure ceases for an instant. Good mechanical condition of the endurance machine is necessary if proper results are to be obtained. When starting the test, care must be taken that the bearing pressure is gradually and uniformly applied.

The endurance test offers a convenient means for study of various problems of lubrication, such as the effect on the oil of different bearing metals, the depreciation of the oil with excessive or scant flow of oil to the bearings, the effect of excessive vibration of the journals, and, possibly, the effect of different gases on lubricating oil during operation. It is believed that the solution of these problems will be greatly aided by means of the endurance test and the work factor.

Work Factor of Turbine Oils

Turbine oils, as manufactured in the United States, show work factors from almost 1.0 to well below the allowable minimum of 0.50. The Navy, like most other large consumers of lubricants, purchases, in widely separated sections, lubricating oils which are made from different crudes and by different processes of refinement. In addition, there are many "freak" oils placed on the market, for which manufacturers make marvelous claims. It is therefore necessary that definite information of the suitability and value be obtained of all oils offered for use. It is not practicable to submit all such oils to extended service tests; first, on account of the possibility of casualties, and, second, because of the time and expense involved. Before an oil is placed aboard ship for a service test, there must be confidence that it will give satisfactory service. If an oil during its endurance test increases abnormally in viscosity, in per cent of carbon residue, in acidity, and in "sludging" matter, it is but a matter of good judgment not to submit such an oil to a service test, but to reject it.

In the early days of the endurance test, year of 1924, a heavy turbine oil was submitted to be tested for naval use. The standard tests for physical and chemical properties indicated the oil to be of such excellent quality that it was sent aboard ship before being subjected to the endurance test. The endurance test of the oil was then run, and it was found to have a work factor of 0.32. The report from the ship stated that the oil became thick and heavy, seriously reducing the flow of oil through the gravity flow boxes, also depositing a heavy sludge, the oil purifier separating out 50 gal. of sludge out of a total run-through of 600 gal. A sample of the sludge was analyzed and found to contain 28 per cent oil, 38 per cent water, and 34 per cent asphaltic matter.

The results obtained from the use of the endurance test in the testing of turbine oils have been so satisfactory that there is a growing conviction that this test is more reliable in indicating the quality of an oil than a single service test. Conditions may arise during a service test which may have a deleterious effect on the oil, for which the oil is not responsible; in an endurance test this is not so possible.

Diesel-Engine Lubricating Oil

The lubricating oil in use in Diesel engines undergoes the following changes:

With engine in good condition, piston rings tight, and combustion satisfactory:

Increase in specific gravity. Flash and fire points and pour point not much affected.

Increase in viscosity, neutralization number, precipitation number, and per cent of carbon residue, to practically the same extent as encountered in a lubricating oil in a force-feed turbine lubrication system.

The oil is darkened more than oil used in a turbine system, but not as greatly as oil used in gasoline engines.

Very little contamination from the fuel.
Demulsifying properties depreciated.

With engine in poor condition, piston rings loose, or combustion unsatisfactory:

Specific gravity decreased.
Flash and fire points considerably decreased.
Pour point decreased.
Viscosity decreased.
Neutralization number, precipitation number, and per cent of carbon residue increases with period of use.
The oil is darkened.
Considerable contamination from the fuel.
Demulsifying properties considerably depreciated.

In view of the foregoing, a high-work-factor oil should prove more stable and be a better lubricant than a low-work-factor oil for use in Diesel engines. This has proved to be true, less troubles are experienced in the use of the higher work factor oils, and oils which have passed satisfactory endurance tests have also passed satisfactory service tests in Diesel engines.

Work Factor of Aviation Oils

The Navy has completed a remarkably successful year in aviation. It is believed that the lubricating oil used in the aviation engines contributed somewhat to this success. In the beginning, aviation was handicapped by a lack of knowledge of the proper oil to use for lubrication. The motor industry, while much older, offered little assistance of value. Even such a simple matter as the proper viscosity oil to be used required a long time for its solution. The advance in aviation engine design from the low-compression water-cooled motor to the high-compression water-cooled motor and then to the high-compression air-cooled motor added to the complications. Lubricating oils which appeared to give good service in the water-cooled motor were not satisfactory for the air-cooled motor. Why such oils proved to be unsatisfactory no one knew. An oil subjected to the standard laboratory tests did not differentiate sharply between good and poor lubricating oils. A great deal of idle conversation was indulged in about high flash points, low per cents of carbon residue, and so on, but such did not advance the art, and consequently many things happened to motors which were difficult to explain.

Since the endurance test demonstrated its value in examining turbine and Diesel engine oils, it was thought that it might possibly be of value in determining the quality of aviation oils. Aviation oils in service are contaminated with the gasoline fuel, but this contamination does not generally exceed 3 per cent by volume. The gasoline absorbed by the oil reduces slightly the viscosity and fire point, and very markedly the flash point, closed cup, of the oil. The neutralization number of the oil is not greatly increased due to the short period of use, but the precipitation number and per cent of carbon residue very often increase greatly, dependent on the quality of the oil.

The endurance test of the aviation oils and the calculated work factor showed that oils which had at one time been considered satisfactory, but had been discarded on account of general poor performance and fouling of the engine, had work factors from 0.50 to as low as 0.10, and, on the other hand, lubricating oils which gave excellent performance and would run indefinitely in the engine with scarcely a sign of carbon deposits on the top of the pistons had work factors of approximately 0.90. The high work factor could not be explained by consideration of carbon residue content of the oil alone, for some of the oils which had very low work factors showed less carbon residue content in the original oil than some of the oils which had high work factors. In fact, it was impossible, and is still impossible, to differentiate between good and poor aviation oils by means of the ordinary standard tests, but it is possible to do so by determination of their work factors. The work-factor method of qualifying aviation lubricating oils has so accurately demonstrated its value by a great number of practical tests that it is scarcely necessary to subject them to service tests in order to prove their suitability. Any one familiar with the operation of high-compression aviation engines recognizes the necessity of maintaining the pistons and cylinders free of carbon deposits; a very slight amount of carbon deposit on these parts greatly increases the detonating properties of the gasoline. While all are aware of the necessity of using gasoline which will withstand the high compression without detonation, very few take into consideration the fact that the use of a lubricating oil which produces carbon deposits on pistons or cylinders is just as objectionable as the use of an unsuitable gasoline. The necessity for the use of high-work-factor aviation oils will become more apparent with the increased use of aviation engines of higher compression ratio.

Purchase of Oils on Work-Factor Basis

Lubricating oils are purchased by the Navy on the service cost per gallon, using the following formula:

$$\text{Service cost per gallon} = \frac{\text{Cost per gallon}}{\text{Work factor}}$$

the low service cost per gallon being considered the low bid. This method of purchase has many advantages, viz.:

(*a*) It creates a means to compare quality with price and allows selection of the most economical oil from the consumer's standpoint.

(*b*) It eliminates the personal element in the decision as to acceptability or non-acceptability of a brand of oil.

(*c*) It is an incentive to refiners to produce oils of higher quality, with some hope of remuneration for the better quality of oils.

(*d*) It offers a ready means of evaluating oils, when considering the factors of safety, upkeep and repair of engines, and length of service; the higher work factor oils increasing the safety of operation and length of service and decreasing the cost of upkeep and repairs.

Conclusion

The object of lubrication is to substitute liquid friction for solid friction in operating machinery. To do this satisfactorily, it is necessary that the liquid possess low internal friction and be capable of long use with minimum change in its properties. The very nature of mineral oils in being resistant to chemical action makes them valuable for lubrication, but this resistance also makes it difficult to evolve satisfactory tests for their quality. The stability of an oil must then be recognized as of great value, but the stability must be determined in a manner which is in agreement with its application; not at too high temperatures or in highly concentrated oxygen atmosphere, but under pressures, temperatures, and in atmospheres which have some relation to service conditions. The results obtained from lubricating oil in service have been the governing factors from which the work-factor evaluation method has been evolved. The changes which take place in the oil in the endurance test and the actual service obtained from the oil are co-related, and consequently form the basis for the work-factor evaluation method.

Discussion

E. H. Thompson.[5] The Petroleum Division is fortunate in obtaining research information such as Messrs. O'Neill, Larson,

[5] Lubricating Engineer, Baltimore Copper Smelting and Rolling Company, Baltimore, Md. Mem. A.S.M.E.

and Hersey have given. The pioneer is the milestone along the pathway of progress. His work frequently stands out above that of the many who profit thereby.

The industrial lubrication engineer can improve operation and reduce costs, but in any one given application his progress is limited by commercial costs and other requirements.

Lubrication engineering, however, is a going concern, and is not necessarily stopped permanently by such conditions. These will eventually yield to further improvement by means of the tools which research from time to time gives us. The measurement of oil-film strength is likely to become such a tool.

NEVIN E. FUNK.[6] The oils used in steam turbines are subjected to the deteriorating influences produced by heat, air, and contact with various metals and with water. Heat, air, and contact with some metals cause changes in the character of oil by oxidization, thus producing some harmful and some harmless combinations from the oil structure.

The harmless combinations remain dissolved in the oil, showing their presence by darkening the oil and increasing its acidity, but do not make sludges or emulsions when brought in contact with water.

The harmful combinations not only darken and acidify the oil, but also are changed from a liquid to the form of semi-solid sludges and emulsions by contact with water, or to sludges even when water is not present, if they are of a certain type and have been formed in sufficient amount.

These sludges and emulsions are suspended in the oil and deposited throughout the lubricating system of the turbine, clogging the system and reducing the flow of oil, covering the cooling coils and reducing the heat transfer, thus increasing the oil temperature and accelerating the deterioration process.

The rate at which sludge and emulsions are produced from an oil has a greater bearing on the practical usefulness of that oil than most of its other characteristics; therefore any test that does not in some manner take into consideration the behavior of serviced oil in the presence of moisture cannot accurately determine the service value of the oil.

The writer agrees with Mr. O'Neill's conclusion that endurance tests made under conditions approaching those of operation are best, and he is therefore led to the conclusion that, for the testing of turbine oils, the elimination of so important a factor as moisture from the test apparatus is very apt to lead to erroneous classifications of lubricating oils.

Mr. Larson in his paper has pointed to this fact and has shown that a material classification error results if the emulsifying tendency of the oil is neglected.

G. B. KARELITZ.[7] Any oil user as well as oil manufacturer would like to have some formula or specification that would enable him to determine by laboratory tests the quality of a product as a lubricant. Any work done along these lines is of high value to the industry, particularly when the amount of work and time necessary for a reliable investigation in this field are taken into consideration.

The oil-testing machine described by Mr. O'Neill has been built apparently with a main object of testing turbine oils. It does not take into consideration the quality of oil which is called oiliness. It is true that some investigators found the performance of oils in internal-combustion engines depending on their viscosity, but there are a number of indications that the lubricating quality of an oil in a reciprocating engine depends on oiliness to a marked degree. The machine must necessarily serve, then, as a good controlling apparatus to differentiate between good oils submitted by oil manufacturers from the standpoint of their durability. Is there not a danger that oils may pass the test and show a service cost per gallon lower than others without having the proper oiliness? The paper by Mr. Larson seems to substantiate such a possibility.

The work test is a further step in oil testing, but there is apparently a long way to go before a reliable specification for purchasing lubricants on the basis of laboratory tests alone can be agreed upon.

A. E. FLOWERS.[8] It should be borne in mind that the work factor as described by Mr. O'Neill represents a quite arbitrary choice of factors to be observed and an entirely arbitrary method of combining results of several different tests into a composite number. Since this method is actually employed by the Navy it is very desirable that information should be made available as to the method of test, but a heavy burden of proof lies upon the author to justify his selections for the method of carrying out the test and evaluating the results.

M. A. DIETRICH.[9] Have any tests been made and are figures available which show any definite relation between the work factor and sludge deposition of lubricating oils in Diesel-engine service? It is difficult to see how this test can measure the resistance to breakdown of oils under such temperature conditions as are encountered in Diesel-engine use.

In steam-turbine lubrication the rate of breakdown and formation of sludge is materially affected by the presence or absence of water. The Navy work test will apparently not measure the effect of steam leaks on the rate of deterioration of an oil.

What were the considerations taken into account in the adoption of the final rejection points for neutralization number and carbon residue? The question of what constitutes a maximum upper limit for neutralization number is subject to considerable dispute.

The test is undoubtedly a considerable improvement over the present arbitrary laboratory methods of test.

ALPHONSE A. ADLER.[10] Mr. O'Neill's paper is timely. It shows progress. Perhaps some day we may be able to specify accurately an oil for a particular purpose so as to encourage progressive manufacturers by rewarding them for a meritorious product and at the same time take effective steps in penalizing those whose product borders on the nebulous. It is frequently a difficult matter to deny a product consideration unless there is a simple, cheap, and effective test which is just and which the objectionable product cannot meet by a wide margin.

Discussion of oil qualities in the past were as meaningless as discussions on what pure air is. The science of air conditioning has recognized certain essential qualities like temperature, humidity, air motion, cleanliness, freedom from odors, freedom of dangerous constituents, etc. By an arbitrary rating, for ventilation purposes, agreement was reached by giving each element a certain weight so that several aggregations of the elementary properties might reach the same percentage. The final result is a measure of fitness of the air for the particular purpose. For example, should the air be required for drying, it is possible that the elements pertaining to odor, cleanliness, etc., may not be as important as they are for breathing purposes. Accordingly a new scale of weights would be agreed upon.

[10] Consulting Engineer, New York, N. Y. Mem. A.S.M.E.

It seems to the writer that some such scheme may be of possible application to oils for specific purposes. One example may suffice. An aircraft oil may be subjected to extremely low temperatures, and it must remain fluid. Another oil may be used in a factory where under no circumstances would the operating temperature fall below about 50 deg. Desirable viscosity at zero would be of no especial value in the latter application.

We should go on with fundamental research to tell the whole story ultimately. In the meantime a partial and somewhat arbitrary analysis is far better than none at all.

Author's Closure

Does the work-factor method of evaluating lubricating oils apply to lubricants for motor cars? The arguments in favor of the affirmative are as follows:

(*a*) The object of lubrication is to substitute liquid friction for solid friction in operating machinery. To do this satisfactorily it is necessary that the oil used for lubrication have low internal friction and be capable of long use with minimum change in its properties. An oil which is unstable and changes rapidly in its properties, when used as a lubricant where the moving parts float on a film of lubricant, is unquestionably not as satisfactory as one which, under the same conditions, shows great resistance to change. The moving parts of a motor-car engine float on a film of oil, and it is reasonable to suppose that an oil which shows great stability in film lubrication will give better service than one of lesser stability. In other words, a high-work-factor oil should be a guarantee of satisfactory operation in any machinery employing film lubrication.

(*b*) Lubricating oil used in the modern Diesel engines is subjected to high heat from the combustion of the fuel and to a fairly long period of service. The conditions under which it is used are between those of a turbine oil and a gasoline-engine oil. During use the main changes in the oil are increases in viscosity, neutralization number, precipitation number, and per cent of carbon residue, or in other words, properties which determine the work factor of the oil; oils having suitable work factors being satisfactory for use in Diesel engines.

(*c*) It is known that certain oils prove excellent lubricants for aircraft engines; they are high-work-factor oils. It is known that certain oils are unsatisfactory for such use; they are low-work-factor oils. Aircraft engines are gasoline engines, and motor-car engines are gasoline engines; however, lubricating oil in an aircraft engine is subjected to more severe service than lubricating oil in a motor car. If it were possible to standardize motor-car-engine operation as thoroughly as is aircraft-engine operation, the quality of the oil, as expressed by the work factor, would be as valuable as it is for aircraft engines. Most of the troubles experienced in motor-car-engine lubrication are due to the use of oil of the wrong viscosity; this trouble is so widespread that it tends to overshadow difficulties which are experienced from the use of poor-quality oils. Consequently, in view of such conditions, it is difficult to obtain widely affirmative data on the value of high-work-factor lubricating oils. The installation on motor cars of reclaimers will tend to standardize their lubrication and will also tend toward the use of more stable or higher-work-factor oils.

It is safe to assume that, if an oil of high work factor is more suitable for use under very severe conditions, as in an aircraft engine, this oil will still be more suitable for use under conditions less severe, but of the same nature, as in motor-car engines.

PME-53-7

Stresses in Dished Heads of Pressure Vessels

By CYRIL O. RHYS,[1] ELIZABETH, N. J.

The paper develops the problem of the proper profile for the dished heads of pressure vessels. The author's company uses large drums for high internal pressures. The results are given of tests made over a period of several years on these drums in which strain-gage readings were taken. The bending stresses therein are more critical than the meridional-loop stresses.

FOR some years past, the problem of the proper profile for the dished heads of boilers and other vessels subjected to internal pressure has been investigated and discussed. As a result a number of papers in technical literature and at least one book, "Ueber die Festigkeit der gewölbten Böden und der Zylinderschale," have appeared. Almost all of these are written in German, and they are not presented in a form convenient for use and reference by the designer. A discussion by Mr. W. M. Coates of a paper presented by Mr. T. W. Greene at the December, 1929, meeting of the A.S.M.E.[2] gives the full theory and shows how it can be applied to heads of elliptical profile.

The main features included in this paper may be described as follows:

The Standard Oil Company (New Jersey) uses large drums for high internal pressures. For several years tests have been made on these and strain-gage readings taken. The drums have sometimes been tested to destruction, and it has been observed that failure has taken place at pressures considerably below what would be predicted by an application of the older formulas, in which the effect of bending stresses is not included.

Most of the heads referred to have profiles made up of two arcs of circles, whose radii are described as the knuckle radius and the crown radius. It is therefore impossible to apply the modern bending-stress theory directly from such a paper as that referred to for elliptical heads. It consequently becomes necessary to develop the theory as applied to these double-radius heads, which have surface discontinuities at the junction of the crown and knuckle as well as at that of the knuckle and shell. This work appears in Appendix No. 1, the final formulas appearing in Table 1, in the body of the paper.

In the following part of the paper, calculations based on these formulas are compared with the results of experiment and test. The effect of such a comparison is best seen by a reference to Fig. 2, in which curves are plotted for the measured and computed strains. As will be observed, the general shapes of the curves show good agreement. The magnitudes of the maximum strains check closely, the differences being on the side of safety.

This appears to show that the theory as developed for the double-radius head corresponds well with the conditions existing in the head of a pressure vessel under load. As the computed strains are obtained directly from the computed stresses by the usual stress-strain relations, it seems reasonable to suppose that the agreement between the computed and actual stresses is equally good. The existing experimental data provide no means for directly checking this, but at all events the theory shows that the pressure causing failure would be accompanied by dangerously high stresses. In other words, the present theory accounts for failure of heads, as the older formulas do not. All the important stresses for the head corresponding with Fig. 2 are plotted on Fig. 1. As will be shown later, the bending stress due to the surface discontinuity between the knuckle and crown (denoted by S'' max) is the greatest unbalanced stress, and will be considered as governing design.

For design purposes a regular procedure is worked out in the body of the paper. It is shown that (for a given diameter and depth of head) particular knuckle and crown radii exist which will make the governing stress a minimum. The plate thickness is calculated from these by the simple relationship

$$S'' \max = \frac{0.147\ PA^2K}{at}$$

which appears in Table 1, the proper radii, as explained, being taken from Table 3. The thickness being determined, other formulas given in Table 1 are used to obtain the remaining important stresses. It can then be ascertained whether, in any particular case, S'' max is or is not the greatest stress existing in the head. The design procedure, in general, leads to proportions for which all the important stresses are of the same order of magnitude, S'' max being somewhat greater than any other net stress.

An interesting comparison can be made of the different thicknesses obtained by the A.S.M.E. rule and the theory including bending stresses. This occupies the last section of the main body of the paper. Examples, illustrated by Figs. 7, 8, 9, 10, and 11, are worked out, which show considerable discrepancies for heads of small knuckle radius. As the best shape of head is approached, these differences tend to disappear.

As already stated, the derivations of all the formulas used are given in Appendix No. 1. It has not been found necessary, as in most of the literature referred to, to go into the somewhat complicated and difficult theory of thin shells. As will be seen, the derivation requires only the ordinary theory of bending, the usual stress-strain relations, and the solution of a simple differential equation.

Appendix 1 also contains the derivation of the equations used in selecting the least value of the governing stress S max, from which Table 3 has been prepared. The recognition of this

[1] General Engineering Department, Standard Oil Development Company. Mr. Rhys was born in London, England, on Jan. 20, 1882. From 1906–1910 he was in the employ of the Globe Pneumatic Engineering Company in London, handling nearly all their designing work. In 1910 he came to the United States and for three years was in the maintenance department of the William Cramp & Sons Ship and Engine Building Company. During 1913 he did engine- and boiler-testing work for the Bowers Southern Dredging Company at Galveston, Tex. He then became a designer of industrial machinery for the Diamond Match Company at Barberton, Ohio, and remained with them until 1918. Shortly after this he became associated with the United Shoe Machinery Company at Beverly, Mass., working in the experimental department. In 1922 he joined the faculty of the Georgia School of Technology, at Atlanta, Ga. In 1924 he entered the employment of the Standard Oil Company.

minimum and the method for finding it are believed to be new.

To sum up, the present paper can be divided up into five main sections:

1 Development of the bending-stress theory of heads for double-radius head profiles.

2 Comparison of theoretical and experimental results.

3 Development of a method for obtaining the profile of least stress for given diameter and depth of head.

4 Formulation of a procedure for design calculation.

5 Comparison of head thicknesses obtained by the A.S.M.E. rule and the bending-stress theory.

BENDING-STRESS THEORY OF HEADS FOR DOUBLE-RADIUS HEAD PROFILES

All the mathematical work for this is shown in Appendix No. 1. Table 1 contains the formulas for the different stresses existing in the head. Table 2 consists of a list of the symbols used in Table 1, together with their physical meaning.

On Fig. 1 are plotted curves showing all the important bending and membrane stresses for a typical drum and double-radius head. Its dimensions, etc., are given, and it is discussed from a different standpoint, under the heading "Comparison of Theoretical and Experimental Results."

The following discussion of this chart may be of assistance in giving an insight into the bending-stress theory of dished heads. The curves shown in full lines are bending stresses and those in dotted lines are membrane stresses. A membrane stress may be defined as a stress accompanied by a purely radial displacement of a point in the material. Instances of this would be given by the stresses in a soap bubble or a bladder subjected to internal pressure. The material consists of a flexible continuous envelope or surface, which can be stressed by stretching. By a continuous surface is meant a surface whose radius of curvature undergoes no abrupt changes in either the unstrained or the strained state. It can easily be seen that if points on such a surface move out in directions normal to the surface, their distance apart (measured on the surface) will increase, and the material will be stretched. The radius of curvature of the surface will increase, so that the material can be considered as "bent," but a flexible surface offers no resistance to bending, and no bending stresses occur.

The foregoing applies to a thin steel shell, with a continuous surface. The membrane stresses exist as described, and since the material is not flexible, there will be bending stresses. As, however, the normal or radial displacements are very small, the change in radius of curvature is relatively insignificant and the bending stresses almost negligible. When, however, one comes to the kind of surface involved by the combination of a cylindrical shell, attached to a double-radius head, there are discontinuities or sudden changes in the radius of curvature. One of these occurs at the junction of the knuckle and crown, and another at the junction of the knuckle and shell. The shell, knuckle, or crown, considered alone, is a continuous surface, and would have only radial displacements, but those in the sharply curved, stiff knuckle would be exceeded by those in the less curved, more flexible shell or crown. Supposing no separation at the junctions to occur, it is easy to see that the knuckle would be bent outward near the junctions, like a trumpet, and the shell and crown would be bent in. Bending stresses of con-

TABLE 2 LIST OF SYMBOLS

A	= radius of crown
a	= radius of cylindrical shell
b	= depth of dished head
e	= base of natural logarithms
H	= membrane hoop stress
H'	= bending hoop stress due to shell-knuckle edge
H''	= bending hoop stress due to crown-knuckle edge
K	= ratio $(A/r - 1)$
k	= ratio a/r
K	= ratio a/b
m	= Poisson's ratio
P	= internal pressure
R	= hoop radius of curvature of knuckle
r	= meridional radius of curvature of knuckle
s	= distance measured from either edge of knuckle, along knuckle, shell or crown surface
S	= membrane meridional stress
S'	= bending meridionol stress due to shell-knuckle edge
S''	= bending meridionol stress due to crown-knuckle edge
t	= thickness of metal—the same in head and shell
u	= ratio (depth of head)/(shell radius) = b/a
w	= radial displacement accompanying bending stresses
w'	= radial displacement accompanying membrane stresses.

1.0	10.00	10.0	0	1.47	1.47

NOTE: See Table 2 for meaning of symbols used.

siderable magnitude are set up in this way. Furthermore, such bending must be accompanied by changes in diameter and consequent large hoop stresses. These are tensile in the knuckle and compressive in the shell and crown.

Consider the curve A on Fig. 1. This represents the outside bending stresses set up by the mutual constraints of the shell and knuckle. It is zero at the junction, since along this boundary the shell and knuckle load each other somewhat after the manner of cantilevers. Going away from the boundary, along the shell or along the knuckle, the stress reaches a maximum and then dies away, as would be expected. The trumpet shape assumed by the knuckle would imply compression, and the inward bending of the shell tension.

Curve B, for the knuckle and crown, is of a character precisely similar to curve A, and the same features apply to it. Curves A and B are combined in the knuckle under S' and S''.

Curve H', in the shell, is the compressive hoop stress set up by the bending inward of the shell end. It is greatest at the boundary, where the decrease in diameter is greatest, and dies away as the decrease becomes less. Curve H'' for the crown is precisely similar. These curves are compressive at any point in the thickness of the plating, and do not change sign for the inside and outside, as the bending stresses do.

Corresponding tensile hoop stresses exist in the knuckle. They are combined under H' and H''.

As these bending hoop stresses are not zero at the boundaries, they illustrate well the discontinuities due to abrupt changes of curvature.

The dotted horizontal lines in the shell are the ordinary hoop and axial stresses in a thin cylinder under internal pressure. They are computed by well-known simple formulas.

The dotted curve in the knuckle marked "S Meridian" is the stress acting tangent to the surface in a plane containing the drum axis. The dotted curve in the knuckle marked "Hoop H" is the membrane hoop stress. It is not evident at first sight that this should be compressive. Consider, however, the shell and crown to be displaced radially outward. Their centers of curvature will still remain on the drum axis, as in their unstrained state, but points on their junctions with the knuckle will be further apart. The knuckle must adjust itself so as still to connect the shell and crown. From a consideration of Fig. 12, it seems almost certain that it does this by shifting the inner end of the knuckle radius and also assuming a flatter curvature. This flattening of the curvature appears to imply a reduction in diameter, with consequent hoop compression. With this and with the trumpet shape due to bending stresses, the strain displacements in the knuckle are of a complicated character, and it is not surprising that, with a sharply curved, stiff form, great stresses result. An inspection of the broken head, Fig. 13, will show that the complete line of fracture lies wholly within the knuckle.

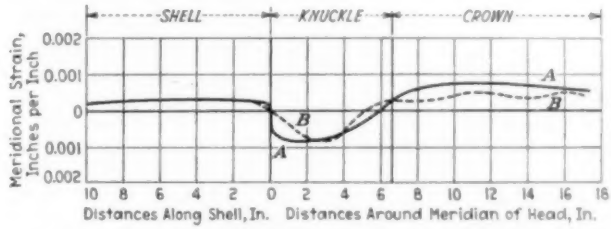

FIG. 2 OUTSIDE MERIDIONAL STRAINS IN HEAD AND SHELL OF 6-FT. BY 40-FT. SOAKING DRUM, PRESSURE 500 LB. PER SQ. IN.
(A, calculated—modulus of elasticity 30,000,000 lb. per sq. in., Poisson's ratio 0.3; B, measured.)

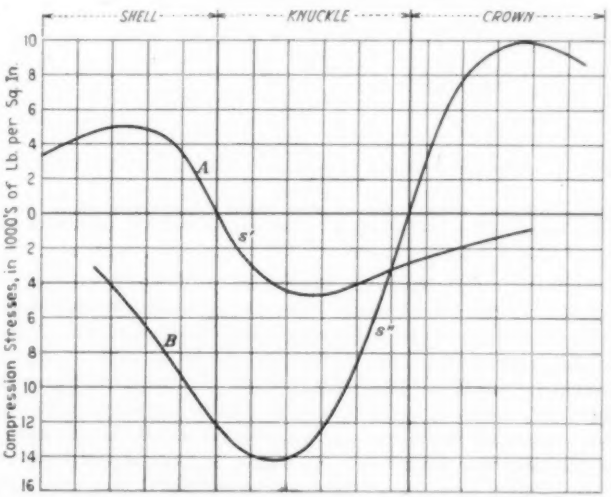

FIG. 3 BENDING STRESSES IN 6-FT. BY 40-FT. SOAKING DRUM
(Knuckle radius, 9.4 in.; crown radius, 55 in.; pressure, 500 lb. per sq. in.; metal, 2 in. thick. A, effect of shell and knuckle; B, effect of crown and knuckle.)

The dotted horizontal line in the crown marked "Meridian and Hoop S and H" (see Fig. 1) represents membrane stresses in a spherical shell under internal pressure. The radius of curvature is constant all over this part of the surface, and the stresses are the same in all directions. All the curves on Fig. 1 are calculated from the corresponding formulas in Table 1. The symbols S, S', etc., H, H', etc., occurring in both Table 1 and Fig. 1, will assist identification.

COMPARISON OF THEORETICAL AND EXPERIMENTAL RESULTS

The following data were taken from a drum subjected to a hydraulic test:

Diameter of cylindrical shell, ft	6
Length, ft	40
Crown radius, in	56
Knuckle radius, in	7

Thickness of head or shell, in.	2
Ratio, head radius to head depth	2
Internal pressure, lb. per sq. in.	500

The stresses plotted in Fig. 1 were calculated from the foregoing. From these, by the usual stress-strain relations, were obtained the strains which are shown in Fig. 2 in comparison with strain-gage readings taken from the drum while under load. The good agreement of theory and experiment in Fig. 2 has already been pointed out.

It will be seen from Fig. 1 that the largest unbalanced stresses are the meridian bending stresses, which reach a value in the

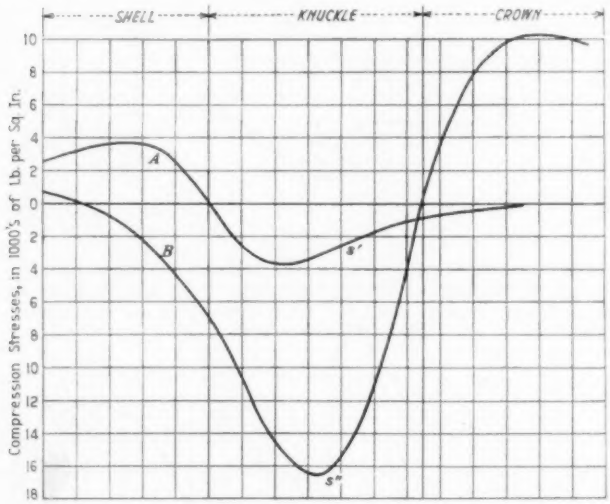

FIG. 4 OUTSIDE BENDING STRESSES IN 6-FT. BY 40-FT. SOAKING DRUM

(Knuckle radius, 12.7 in.; crown radius, 66.5 in.; shell radius, 36 in.; pressure, 500 lb. per sq. in. *A*, effect of shell and knuckle; *B*, effect of crown and knuckle.)

knuckle of about 25,000 lb. per sq. in. This is for an internal pressure of 500 lb. per sq. in. The pressure was increased up to 1600 lb. per sq. in., when failure of the head took place. If the stress-strain ratio remained constant, the stress at this pressure would be 75,000 to 80,000 lb. per sq. in. As is well known, however, the theory only applies up to the elastic limit (in this case about 32,000 lb. per sq. in.), beyond which the calculated stress in general comes out too high. In the present instance the ultimate strength of the material is 50,000 lb. per sq. in. Although the test data do not permit of any direct check as to stress magnitude, the theory at least indicates that rupture would be expected for the pressure which actually accompanied it. The photograph of the broken head (see Fig. 13) has every indication that failure was caused by a high meridional bending stress in the knuckle.

Following are given some examples of applying the formula

$$S'' \text{ max} = \frac{0.147\, PA^2K}{at}$$

to the results of tests. Although the stress equations do not apply beyond the elastic limit of the material, the following results show that failure would be expected.

A head of the dimensions

Crown radius	= 56	in.
Knuckle radius	= 6	in.
Shell radius	= 36	in.
Thickness	= 1.62	in.
Depth of head	= 18	in.

failed at a pressure of 1200 lb. per sq. in. Applying the formula

$$S'' \text{ max} = \frac{0.147\, PA^2K}{at}$$

there is obtained

$$S'' \text{ max} = \frac{0.147 \times 1200 \times 3136 \times 8.33}{36 \times 1.62} = 79{,}000 \text{ lb. per sq. in.}$$

This would certainly indicate rupture, and the nature of the fracture corresponds with failure by meridional bending stress.

After breaking, this head was replaced by one with a 10-in. knuckle radius. From Table 3 it is seen that this is very close to the "best head," which would have a knuckle radius of $\frac{2.59 \times 36}{10} = 9.4$. At 1800 lb. per sq. in., leakage at the shell joints began to occur, and the test was interrupted to make provision for preventing this. Applying the formula, there is obtained, for the stress at this juncture

$$S'' \text{ max} = \frac{0.147 \times 1800 \times 3136 \times 4.6}{36 \times 2} = 53{,}000 \text{ lb. per sq. in.}$$

On continuation of the test, this head finally broke at 2350 lb. per sq. in. From the formula a stress would be indicated of

$$S'' \text{ max} = \frac{0.147 \times 2350 \times 3136 \times 4.6}{36 \times 2} = 69{,}000 \text{ lb. per sq. in.}$$

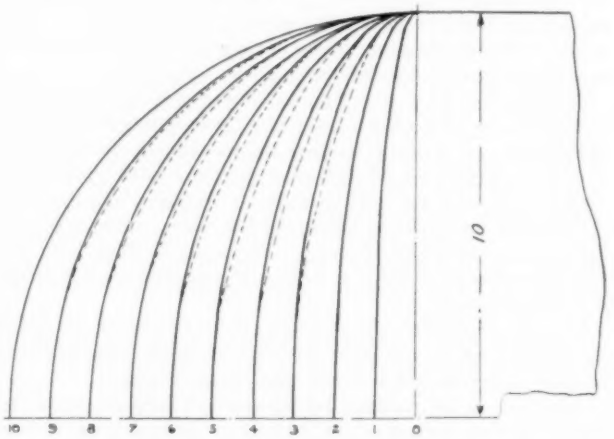

FIG. 5 LEAST-STRESS TWO-RADIUS HEADS COMPARED WITH ELLIPTICAL HEADS

(Broken lines, optimum two-radius heads; solid lines, elliptical heads.)

The head corresponding with the chart of Fig. 1 has a knuckle radius of 7 in. and a crown radius of 56 in. Fig. 3 shows what the bending stresses become when these radii are made 9.4 and 55, the meridian being now approximately an ellipse. The ratio (radius of head divided by its depth), or 2.1, remains the same. The stresses are reduced by about 33 per cent. Looking at the equation for S'' max in the knuckle (Table 1), it is seen that the stress varies directly as A^2K. As shown in Appendix 1, A^2K has a minimum value, with which the latter pair of radii above correspond. For the original head $A^2K = 56 \times 56(56/7 - 1) = 21{,}952$, while for the approximately elliptical head $A^2K = 55 \times 55(55/9.4 - 1) = 14{,}670$. This illustrates the change of stress with the change in knuckle radius. Fig. 4 shows bending stresses with 12.7 in. and 65 in. radii. They are somewhat more than for Fig. 3, as would be expected.

The greatest value of the combined bending-stress curves in Fig. 3 is 18,500 lb. per sq. in. At the inside surface there must

be added to this the meridian membrane stress (see S, Table 1) of

$$\frac{500 \times 36}{2 \times 2} = 4500 \text{ lb. per sq. in.}$$

giving 23,000 lb. per sq. in. in all.

The calculations and curves discussed in the foregoing appear to show good agreement with the results obtained from the 6-ft. by 40-ft. head by actual measurement. In practical design, however, the time involved in going through all this would be prohibitive, and a simpler method of analyzing head stresses must be sought.

If the expression for S'' max is taken from Table 1 and is applied to the foregoing case, there is obtained

$$\text{max bending stress} = \frac{0.147 \times 500 \times 55^2 \times 4.85}{36 \times 2} = 15{,}000 \text{ lb. per sq. in.}$$

and if there is added to this the 4500 lb. per sq. in. membrane stress, there is obtained at once a total of 19,500 lb. per sq. in. as against 23,000 obtained by more elaborate methods. This result is probably very much on the safe side. The crown-knuckle bending stress (curve S'', Figs. 1, 3, or 4) is derived using the hypothesis that there exists a sudden, sharp change of radius at the crown-knuckle edge. A very slight consideration of the manufacturing processes of drum heads will show

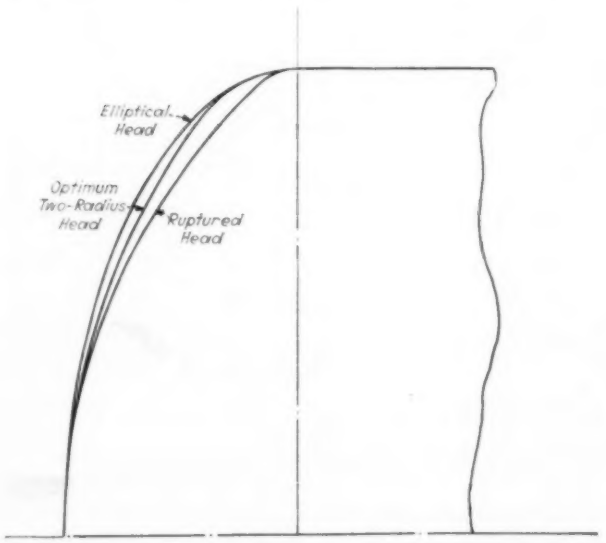

FIG. 6 FAILED HEAD OF A 6-FT. BY 40-FT. DRUM COMPARED WITH THE ELLIPSE AND THE OPTIMUM DOUBLE-RADIUS CURVE

that any such discontinuity as this is almost inconceivable. The knuckle and head almost certainly merge into each other much more gradually, with a consequent reduction in the bending stress. It also has to be remembered that the distortion of the head under pressure has the effect of still further reducing the stress.

From the foregoing considerations it is proposed that the equation

$$S'' \text{ max} = \frac{0.147\, PA^2K}{at}$$

be taken as giving the stress which governs the design of the head.

As an example, this will be applied to the 6-ft. by 40-ft. by 2-in. thick drum with the 400 lb. per sq. in. pressure, for which it was originally designed. (See Tables 1 and 2.)

For the original head, 7-in. knuckle radius, 56-in. crown radius, K would be $56/7 - 1 = 7$. Then the maximum bending stress in the head would be

$$S'' \text{ max} = \frac{0.147 \times 400 \times 3136 \times 7}{36 \times 2} = 18{,}000 \text{ lb. per sq. in.}$$

which is somewhat high. For 500 lb. this would be 22,500 lb. per sq. in. See (*) near S'' curve in Fig. 1 for comparison with

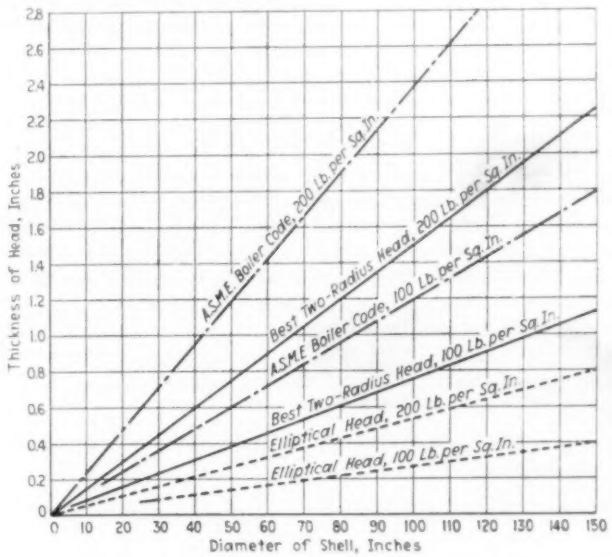

FIG. 7 THICKNESS OF HEAD VERSUS DIAMETER OF SHELL FOR ELLIPTICAL HEADS

(Allowable stress, 11,000 lb. per sq. in. All cases calculated by bending-stress formula.)

more elaborate method. For the 1600 lb. per sq. in. at which the head gave way, the stress would be 72,000 lb. per sq. in. As before pointed out, the stress-strain equations cease to apply accurately beyond the proportional limit, but such a result at least indicates a stress far exceeding this limit, with accompanying grave danger.

The other important stresses in the head are arrived at as follows:

There will be a bending hoop stress in the knuckle of

$$H'' \text{ max} = \frac{400 \times 3136 \times 7}{4 \times 36 \times 2} = 30{,}400 \text{ lb. per sq. in.}$$

and a membrane-hoop stress of

$$H = \frac{400 \times 56}{2 \times 2}(2 - 8) = -33{,}600 \text{ lb. per sq. in.}$$

These two stresses both occur at the knuckle-crown edge, and practically balance each other. Other stresses in the knuckle are relatively unimportant. (See Fig. 1.)

In the crown the maximum bending stress is given by

$$S'' \text{ max} = \frac{0.147 \times 400 \times 56 \times 7}{2} = 11{,}500 \text{ lb. per sq. in.}$$

There would be a bending hoop stress of

$$H'' \text{ max} = \frac{-400 \times 56 \times 7}{4 \times 2} = -19{,}600 \text{ lb. per sq. in.}$$

and a membrane hoop stress of

$$H = \frac{400 \times 56}{4} = 5600 \text{ lb. per sq. in.}$$

leaving a net hoop stress of —14,000 lb. per sq. in. which rapidly decreases as the boundary is left. This result is probably somewhat too high due to the non-existence of really sudden change of curvature.

In the shell, $k = 5.14$ (see Table 2) and the maximum bending stress is

$$S' \text{ max} = \frac{0.147 \times 400 \times 36 \times 5.14}{2} = 5430 \text{ lb. per sq. in.}$$

to which must be added the membrane axial stress of

$$S = \frac{400 \times 36}{2 \times 2} = 3600$$

giving a total meridian stress of 9030 lb. per sq. in. In this case the sudden change of curvature actually exists, as the shell and head are two separate pieces. The efficiency of the riveted joint between shell and head has also to be considered, which will make this stress somewhat more.

There is a bending hoop stress of

$$H' \text{ max} = \frac{-400 \times 36 \times 5.14}{4 \times 2} = -9250 \text{ lb. per sq. in.}$$

which rapidly dies away, as the boundary is left and a membrane hoop stress of

$$H = \frac{400 \times 36}{2} = 7200 \text{ lb. per sq. in.}$$

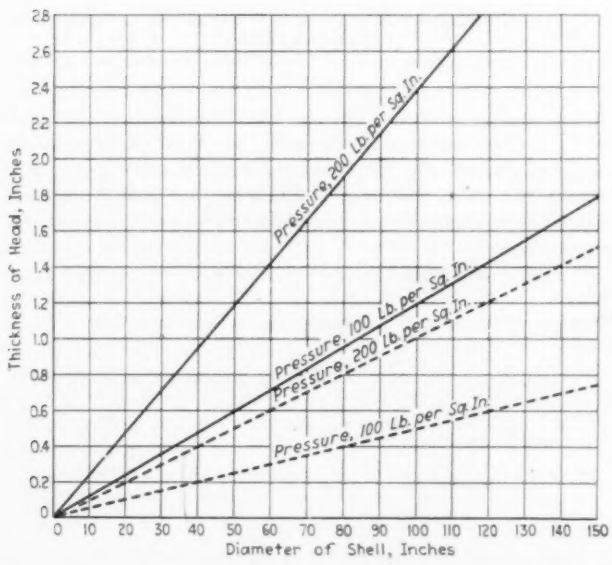

FIG. 8 THICKNESS OF A.S.M.E. HEADS VERSUS DIAMETER OF SHELL
(Knuckle radius = 6% of shell diameter. Solid line, thickness by bending-stress formula; broken line, thickness by A.S.M.E. rule.)

which is the same everywhere. The riveted joint efficiency also increases this.

From the foregoing, the 18,000 lb. per sq. in. bending stress in the knuckle is the stress which should govern design. For the head considered, it is considerably too high. If a head is taken of approximately elliptical form, the knuckle and crown radii would be 9.4 in. and 55 in., respectively (see Table 3), or $K = 55/9.4 - 1 = 4.85$. The maximum bending stress in the knuckle would be

$$S'' \text{ max} = \frac{0.147 \times 400 \times 3025 \times 4.85}{36 \times 2} = 11{,}900 \text{ lb. per sq. in.}$$

Other stresses would change correspondingly. The different stresses in the two cases are given, for purposes of comparison, as follows:

k	5.14	3.82
K	7	4.85
Knuckle radius, in.	7	9.4
Crown radius, in.	56	55
Shell radius, in.	36	36
Ratio radius to depth, in.	2	2
Maximum bending stress in knuckle, lb. per sq. in., S'' max.	18,000	11,900
Maximum bending stress in crown, lb. per sq. in., S'' max.	11,500	7,850
Maximum hoop stress in crown (net), lb. per sq. in., $H - H''$ max.	—14,000	—7,800
Maximum meridian stress in shell, lb. per sq. in., $S + S'$ max.	9,030	7,650
Maximum hoop stress in shell, lb. per sq. in., H	7,200	7,200

For the large knuckle radius, the bending stress in the knuckle still governs the design. If 70 per cent is taken for the efficiency

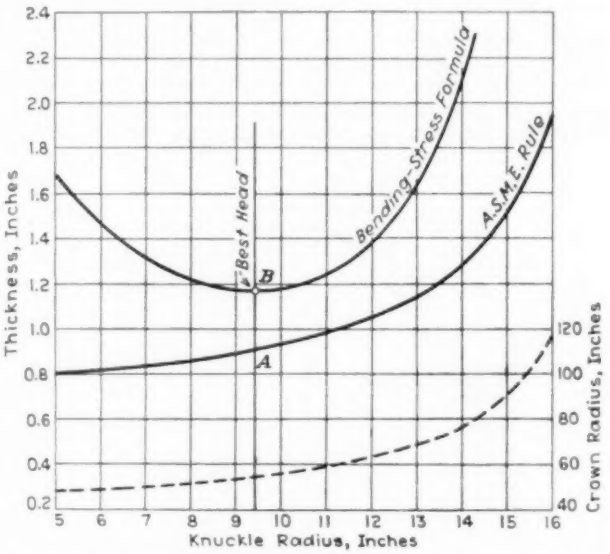

FIG. 9 KNUCKLE RADIUS VERSUS HEAD THICKNESS AND CROWN RADIUS
(Shell diameter, 72 in.; depth of head, 18 in.; pressure, 200 lb. per sq. in. Solid line, head thickness; broken line, crown radius.)

of the riveted joint, there is a hoop stress H in the shell of 10,300 lb. per sq. in. This may be further increased by the effect of manheads, showing that, taking

$$S'' \text{ max} = \frac{0.147\ PA^2K}{at}$$

as the governing stress, gives maximum stresses in the head and shell, which are in fair agreement. In the above, the stresses have been calculated from the given dimensions. If the maximum stress be decided upon first, the thickness can of course be obtained by simple transformation, or

$$t = \frac{0.147\ PA^2K}{a.S'' \text{ max}}$$

If the meridian were formed by one continuous curve, such as an ellipse, so that the radius of curvature varied gradually, the bending stresses due to the crown-knuckle joint would disappear altogether. It might be pointed out, however, that a perfect

ellipse is just about as unlikely as a sudden change of radius. The treatment adopted in this report is based on the assumption of conditions somewhere between these two improbabilities. The results show good agreement with the facts brought out in testing the 6-ft. by 40-ft. soaking drum to destruction, and the discrepancies are on the side of safety.

Profile of Least Stress

From the foregoing it will be seen that, for a given diameter and depth of head, more than one "two-radius" meridian curve can be used. There can be any number of such curves, and, as shown in Appendix No. 2, one of them will give the lowest value for the maximum bending stress. Table 3 has been prepared, from which the crown and knuckle radii for the best "two-radius" head can be selected. The formulas for the greatest bending stresses are also given. For the sake of comparison and completeness, the formula for an elliptical head is included. It

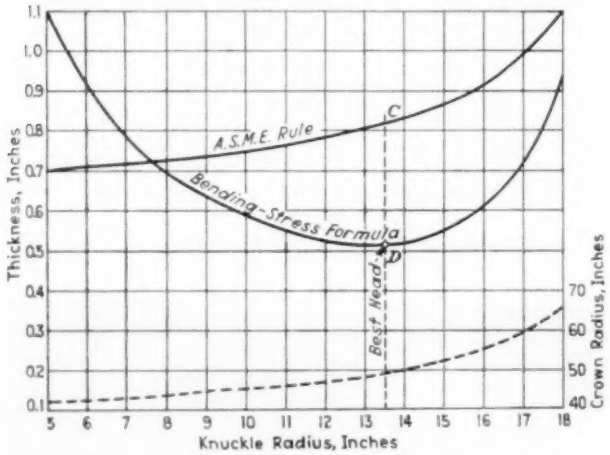

Fig. 10 Knuckle Radius Versus Head Thickness and Crown Radius

(Shell diameter, 72 in.; depth of head, 21 1/2 in.; pressure, 200 lb. per sq. in. Solid line, head thickness; broken line, crown radius.)

might be noted that for the two-radius head, the bending stress is set up by the crown-knuckle junction. For the elliptical head it is set up by the head-shell junction.

In Table 3 the shell radius is taken as 10 in., the internal pressure as 1 lb. per sq. in., and the plate thickness as 1 in. For other values the numbers in the table will change in proportion. Thus for a head where $u = 0.5$, $a = 36$ in., $P = 400$ lb. per sq. in., and $t = 2$ in., there would result

$$S'' \text{ max} = \frac{16.5 \times 3.6 \times 400}{2} = 11{,}900 \text{ lb. per sq. in.}$$

as in the previous example.

Columns 4 and 5 in Table 3 refer to stresses in double-radius heads. Note that in very deep heads, column 5 may give the governing stress. Column 6 is for elliptical heads, and the use of the table for these is self-evident from the foregoing.

Fig. 5 shows the optimum (or least-stress) two-radius heads compared with elliptical heads. As will be seen, the correspondence is close, being almost exact in the knuckle, where the important stresses come. As will be seen from the chart, when the crown is displaced radially under load, the head profile is brought still closer to the elliptical shape. It is of interest to note this coincidence, as it agrees with results of experiments made by Continental investigators.

Fig. 6 shows the head of a 6-ft. by 40-ft. drum, which failed under test, compared with the ellipse and the optimum double-radius curve. The very marked divergence of the ruptured head from the other two, especially at the knuckle, can be readily noted.

Procedure for Practical Design

For practical design the following procedure is tentatively proposed.

Assuming the depth of the head and the shell diameter to be known, the knuckle and crown radii for the optimum head can be selected from Table 3 from columns 2 and 3. For most heads the governing stress is found by means of the formula for S'' max in column 4. For very deep heads as stated in the explanation of Table 3, the governing stress may be that given for S' max in column 5. Column 6, in the table, brings out the great advantage of elliptical heads, except in cases where the hemispherical form is approached.

The internal working pressure being known, a thickness can now be assumed and the governing stress can be calculated, or the stress can be assumed and the thickness can be determined. The other stresses can now be computed, and it can be seen whether the principal stresses in the head and shell (usually the head bending stress and the shell membrane hoop stress) show no great discrepancy. In making this comparison, the increase in the shell hoop stress due to the riveted-joint efficiency should be allowed for and the effect of manheads considered. The

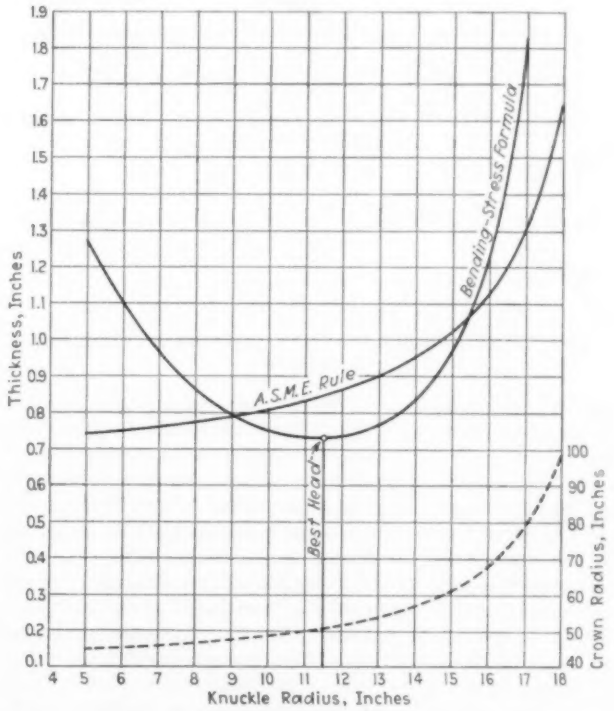

Fig. 11 Knuckle Radius Versus Head Thickness and Crown Radius

(Shell diameter, 72 in.; depth of head, 20 in.; pressure, 200 lb. per sq. in. Solid line, head thickness; broken line, crown radius.)

+ and — membrane and bending hoop stresses also can be checked against each other, the largest difference appearing to be in the crown at its junction with the knuckle. As shown in the foregoing, a radius-to-depth ratio of 2 to 1 gives good results, but special cases may arise in practice which are better suited by different proportions.

Comparison of Head Thicknesses by A.S.M.E. Rule and Bending-Stress Theory

In Fig. 7 are plotted thickness of head against diameter of shell for elliptical heads, "best" two-radius heads (see Table 3), and heads with a knuckle radius of 6 per cent of the shell diameter as permitted by the A.S.M.E. Boiler Code. The last named have an exceedingly small knuckle radius, which gives a meridian curve considerably different from an ellipse. It will be noticed

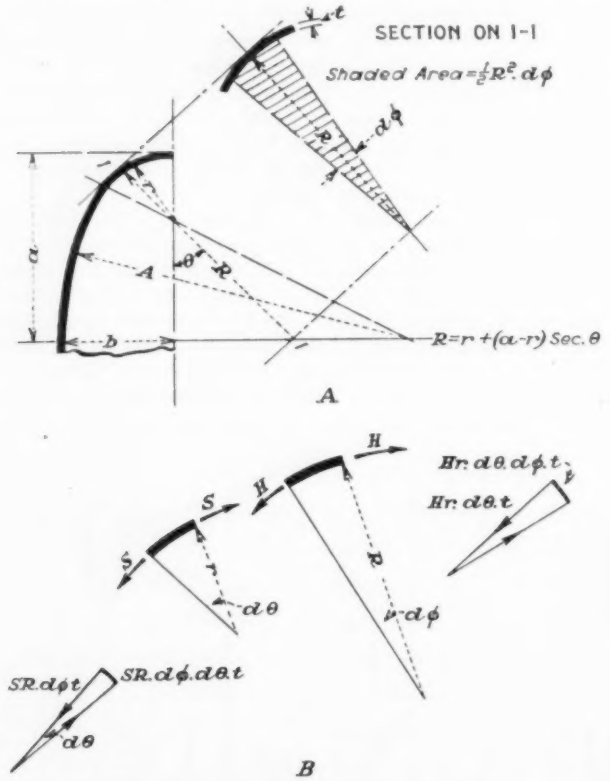

Fig. 12 Head Sections and Force Diagrams for Stress Calculation

that the thickness for the "best" two-radius heads (which is obtained by means of Table 3) lies between the A.S.M.E. head on the one hand and the exactly elliptical head on the other.

The thickness formulas for the three heads plotted reduce to A.S.M.E., 0.000119 *DP;* best two radius, 0.000075 *DP;* elliptical, 0.0000268 *DP*—where *D* is the shell diameter in inches and *P* the internal pressure in pounds per square inch. For other pressures than those given the thicknesses are obtained by simple proportion. For instance, take a "best head" of diameter 72 in. for 400 lb. per sq. in. pressure. For the 200 lb. per sq. in. line on the chart (see Fig. 7) 72 in. diameter corresponds with 1.08 in. thickness, so that 400 lb. per sq. in. would require 2.16 in. thickness. The chart is based on a fiber stress of 11,000 lb. per sq. in. Compare the 2.16 with 2 in. for 11,900 lb. per sq. in. given previously. Again, calculating from Table 3 there should be obtained

$$S'' \text{ max} = \frac{16.5 \times 3.6 \times 400}{2.16} = 11{,}000 \text{ lb. per sq. in.}$$

For any other stress than 11,000 lb. per sq. in., the thicknesses will be obtained by simple proportion.

Fig. 8 shows the thickness required for A.S.M.E. heads with a knuckle radius of 6 per cent of the shell diameter, as calculated by the meridian bending-stress formula and the A.S.M.E. rule. The great increase of thickness required to take care of the crown-knuckle bending stress will be noticed. The knuckle radius is so small that the bending stresses become very high, and these are not taken into account in the A.S.M.E. rule.

With a larger knuckle radius the bending stresses are reduced, and the discrepancy between the A.S.M.E. rule and the bending-stress formula tends to disappear. As an instance, take a head 72 in. in diameter and 18 in. deep. From Table 3 it is seen that $u = 0.5$, and the best shape would be given by a knuckle radius of $2.59 \times 3.6 = 9.35$ in. and a crown radius of $15.2 \times 3.6 = 55$ in. Let the internal pressure be 200 lb. per sq. in., and the tensile strength of the steel be 50,000 lb. per sq. in. Applying the A.S.M.E. rule, for the thickness there is

$$t = \frac{8.33 \times 200 \times 55}{2 \times 50{,}000} = 0.92 \text{ in.} \quad \text{[A]}$$

Calculating from Table 3 and using a factor of safety of 5 (or S'' max = 10,000) there would be

$$t = \frac{16.5 \times 200 \times 3.6}{10{,}000} = 1.19 \text{ in.} \quad \text{[B]}$$

If the depth of the head is increased to $21\frac{1}{2}$ in., or $u = 0.6$, the crown radius for the best shape becomes $13.6 \times 3.6 = 49$ in. The A.S.M.E. rule then gives

$$t = \frac{8.33 \times 200 \times 49}{2 \times 50{,}000} = 0.82 \text{ in.} \quad \text{[C]}$$

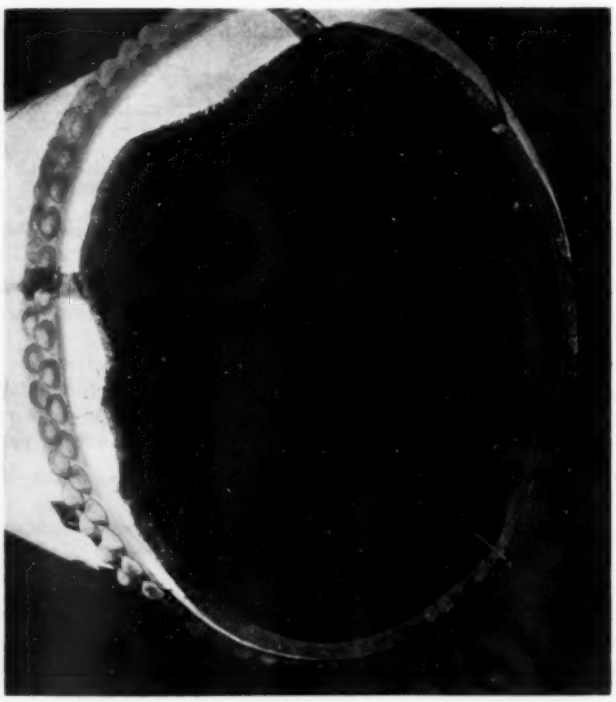

Fig. 13 Broken Head, Showing Line of Fracture Wholly Within the Knuckle

and, calculating from Table 3,

$$t = \frac{7.12 \times 200 \times 3.6}{10{,}0000} = 0.52 \text{ in.} \quad \text{[D]}$$

It thus is seen that, for a value of u (the depth of head/shell radius ratio) somewhere between 0.5 and 0.6, the A.S.M.E.

rule agrees with the bending-stress formula for the best-shaped two-radius head. A head of such proportions would be in accordance with good modern practice. It is interesting to note that the A.S.M.E. rule, the result of long and widespread practical experience, conforms with a bending-stress formula derived from purely mathematical considerations. It is further noteworthy that this conformity occurs only when rule and formula are applied to that head whose meridian contour is theoretically the best.

The foregoing calculations correspond with points *A*, *B*, *C*, and *D* on Figs. 9 and 10. These charts, together with the chart of Fig. 11, illustrate the effect of the small 6 per cent knuckle radius, as shown by the bending-stress formula. They also bring out clearly the existence of an optimum head, or one which requires the least thickness, either a small knuckle radius or a large crown radius accompanying high bending stresses. This can be seen by inspection of the formula for S'' max, reference being made to Table 2 for the full significance of the symbols. These charts also demonstrate how the A.S.M.E. rule and the bending-stress formula approach each other in the neighborhood of the "best head" for heads of about the proportions shown.

If it is desired to compare the A.S.M.E. rule for elliptical heads with the theory, one can proceed as follows: Take a head 72 in. in diameter, 18 in. deep, and 200 lb. per sq. in. pressure, as before. Let the safe working stress be taken as 10,000 lb. per sq. in.

The A.S.M.E. rule requires that, for such a head, the thickness shall be the same as that of the accompanying (seamless) shell. This is given by the formula

$$t = \frac{36 \times 200}{10{,}000} = 0.72 \text{ in.}$$

Applying Table 3, the required thickness would be

$$6 = \frac{5.88 \times 3.6 \times 200}{10{,}000} = 0.425$$

or, for the 0.72 in. thickness, an application of Table 3 would give a fiber stress of

$$S = \frac{5.88 \times 3.6 \times 200}{0.72} = 5860 \text{ lb. per sq. in.}$$

From the first two equations preceding, it is easy to see that the thickness would be 0.72 in each case, if the value 5.88 (see column 6 of Table 3) were changed to 10. This would correspond with a value of u (column 1 of Table 3) of slightly less than 0.4. It is thus seen that the A.S.M.E. rule would require a dish depth of about 25 per cent more than that called for by the theory, for the same thickness of metal.

From these considerations it would appear that the A.S.M.E. specifications for elliptical heads are well on the safe side.

It might be noticed that for any head diameter to dish-depth ratio there is one and only one ellipse, instead of an indefinite number, as in the case of the two-radius head. Such charts as those of Figs. 9, 10, and 11 are therefore impossible in this comparison.

Appendix No. 1

Derivation of Stresses in Heads and Shells of Pressure Vessels

CONSIDER a cylindrical drum with dished heads. Let a be the radius of the shell or cylindrical portion, r the knuckle radius, and A the crown radius; let t be the thickness and P the internal pressure; R is the radius of the curvature in a direction at right-angles to the knuckle curvature $1/r$.

For the shell, considered alone, the stresses are given by the well-known simple relations:

$$\text{Hoop stress} = H = \frac{aP}{t} \quad \ldots\ldots [1]$$

$$\text{Axial stress} = S = \frac{aP}{2t} \quad \ldots\ldots [2]$$

The strain displacements are radial only. If a point in the shell is moved from radius a to radius $a + w'$, the circumference will increase from $2\pi a$ to $2\pi(a + w')$, and the hoop strain will thus be

$$\frac{2\pi\ (a + w') - 2\pi a}{2\pi a} = \frac{w'}{a}$$

There can then be written, by the usual stress-strain equation:

$$\frac{w'}{a} = \frac{1}{E}(H - mS)$$

$$= \frac{aP}{2Et}(2 - m)$$

from [1] and [2], or

$$w' = \frac{a^2P}{2Et}(2 - m) \quad \ldots\ldots [3]$$

In the head, it is seen that the total pressure acting normally to a small sector of area $\frac{1}{2} R^2 \cdot d\phi$ (see Fig. 12-A, section 1-1) would be

$$\frac{1}{2}PR^2 \cdot d\phi \quad \ldots\ldots [4]$$

and this would be accompanied by a normal tension over an area of metal equal to

$$tR \cdot d\phi \quad \ldots\ldots [5]$$

so that the stress in the direction of a tangent to the head, in a plane passing through the axis, would be [4] divided by [5], or

$$S = \frac{PR}{2t} \quad \ldots\ldots [6]$$

Fig. 12-B represents an element of the knuckle. It has radii of curvature r and R for directions at right-angles. The edges are subjected to forces of $SRd\phi t$ and $Hr \cdot d\theta \cdot t$. Their radial components are $SRd\phi d\theta t$ and $Hr \cdot d\theta d\phi t$. They are balanced by the total pressure over the area or $PR \cdot d\phi \cdot r \cdot d\theta$. Putting the pressure equal to the sum of the two radial components, and transposing, gives

$$Hrt = PRr - S \cdot Rt$$

$$H = PR/t - SR/r$$

Substituting from [6], gives

$$H = S(2 - R/r) \quad \ldots\ldots [7]$$

By the same procedure as for the shell, the radial displacement is

$$w' = \frac{PR^2}{2Et}(2 - R/r - m) \quad \ldots\ldots [8]$$

In the crown, R and r are each equal to A, and the radial displacement is

$$w' = \frac{PA^2}{2Et}(1 - m) \quad [9]$$

These displacements are for the shell, knuckle, and crown acting alone. From [3] and [9] it is seen that the displacements are the same, everywhere in the shell and everywhere in the crown. Equation [8] shows that displacement varies in the knuckle, since R changes gradually from A at the junction of the crown and knuckle to a at the junction of the shell and knuckle. There then are, for these edges, proportional radial displacements as follows:

Crown	$(1 - m)$
Knuckle	$(2 - A/r - m)$
Shell	$(2 - m)$
Knuckle	$(2 - a/r - m)$

The radial displacement is positive outward. It is thus seen that the crown and shell expand. Since, for all reasonable proportions, a/r and A/r are numerically more than 2, the knuckle, if free to do so, would contract. This agrees with [7], which shows that the hoop stress would be compressive if R/r exceeded 2. As the crown, knuckle, and shell are not free of each other, it is easy to see from the foregoing that the knuckle will tend to be bent outward at the edges, like a trumpet, while the shell and crown will tend to be bent in. The bending moments will be zero at the edges, since they change sign there. This can also be seen from the fact that the meridian curve will have points of inflection at the junctions of the crown, knuckle, and shell, and the bending moment will there be zero, as in a beam fixed at the ends.

Accompanying bending will be a hoop stress, quite apart from that already derived for simple pressure. The trumpet shape assumed by the knuckle sets up hoop tension. The corresponding inward bending of the shell and crown bring about hoop compression.

There will also be the usual shear stresses, which occur with bending moment.

Let s be the distance measured along the meridian of the knuckle from the shell-knuckle edge. There would then result by the fundamental equation of bending moment (see "Calculus for Engineers," John Perry, p. 108, or other textbook)

$$\frac{d^2M}{ds^2} = F \quad [10]$$

where M = bending moment and F = the force, acting normally to the knuckle surface, per unit of length s. This corresponds with the distributed load on an ordinary beam; i.e., so many pounds per inch.

In a thin cylinder or shell, the bending hoop stress can be taken as constant over the thickness t. Let the bending hoop force per unit of length s be called h, so that h/t = bending hoop stress. The radial component of h is obtained by the method described in the paragraph following Equation [6], and is h/R per unit of length s for a strip of unit width. It is easy to see that this is numerically equal, though of opposite sign, to the force (or distributed load) per unit of length accompanying bending. There is thus obtained from [10]

$$\frac{d^2M}{ds^2} = \frac{-h}{R} \quad [11]$$

Since the hoop strain is w/R, the usual stress-strain relation gives

$$\frac{w}{R} = \frac{1}{E}\left(\frac{h}{t} - S'm\right)$$

where S' is the stress in the s direction and m is Poisson's ratio. Since t is relatively small, and the + bending stresses are equal to the — bending stresses, there can be used the average value of S' or O. Then

$$\frac{w}{R} = \frac{h}{Et} \quad [12]$$

or

$$\frac{h}{R} = \frac{Etw}{R^2}$$

and there is obtained from [11]

$$\frac{d^2M}{ds^2} = \frac{-Etw}{R^2} \quad [13]$$

To get M, the bending moment, take the well-known equation

$$\frac{d^2w}{ds^2} = \frac{M}{EI} \quad [14]$$

A little consideration will show that the narrow meridional strips, considered as beams, cannot deform laterally, as does an ordinary beam. The stress-strain equations would then be of the form

$$\text{Strain in the } s \text{ direction} = \frac{1}{E}\left(S' - \frac{hm}{t}\right)$$

$$\text{Strain in the } h \text{ direction} = \frac{1}{E}\left(h - \frac{mS'}{t}\right) = 0$$

or it can be stated that the net lateral strain for a thin strip is taken as 0, the + strains for one half thickness canceling the — strains for the other half thickness. In any case, from the foregoing equations

$$\text{Strain in the } s \text{ direction} = \frac{S'}{E}(1 - m^2)$$

or E is replaced by $\dfrac{E}{1 - m^2}$ in calculating the bending moment.

I = the moment of inertia of a strip section of unit width = $t^3/12$ (unit width is taken for convenience, since the width cancels out in the final result), and from [14]

$$M = \frac{Et^3}{12(1 - m^2)}\frac{d^2w}{ds^2} \quad [15]$$

Differentiating twice

$$\frac{d^2M}{ds^2} = \frac{Et^3}{12(1 - m^2)} \cdot \frac{d^4w}{ds^4}$$

Substituting this in [13] and transposing, gives the differential equation

$$\frac{d^4w}{ds^4} + \frac{12(1 - m^2)}{R^2t^2}w = 0$$

If there is taken

$$4n^4 = \frac{12(1 - m^2)}{R^2t^2} \quad [16]$$

or

$$n = \sqrt[4]{\frac{3(1 - m^2)}{R^2t^2}}$$

the differential equation becomes

$$\frac{d^4w}{ds^4} + 4n^4w = 0$$

Symbolically $(D^4 + 4n^4)w = 0$

The four roots of this are $n(1 + i)$, $-n(1 + i)$, $n(1 - i)$ and $-n(1 - i)$, which give the solution

$w = b_1e^{-n(1+i)s} + b_2e^{-n(1+i)s} + b_3e^{n(1+i)s} + b_4e^{n(1-i)s} = e^{-ns}(a_1 \cos ns + a_2 \sin ns) + e^{ns}(a_3 \cos ns + a_4 \sin ns)$

Experiment shows that the bending moment dies out as s gets large. This can be possible only if a_3 and a_4 vanish.

By differentiation

$$\frac{dw}{ds} = ne^{-ns}\left[(a_2 - a_1)\cos ns - (a_2 + a_1)\sin ns\right]$$

$$\frac{d^2w}{ds^2} = 2n^2e^{-ns}\left[a_1 \sin ns - a_2 \cos ns\right]$$

At the edge, where $s = 0$, there is a point of inflection (see second paragraph following Equation [9]) or $\frac{d^2w}{ds^2} = 0$ there. The last equation then shows that $a_2 = 0$, or

$$\frac{d^2w}{ds^2} = 2a_1n^2e^{-ns}\sin ns \quad \ldots\ldots\ldots\ldots [17]$$

and

$$w = a_1e^{-ns}\cos ns$$
$$= a_1 \text{ when } s = 0 \quad \ldots\ldots\ldots\ldots [18]$$

Note that n is a function of R, so that this solution applies for a small arc, over which R may be regarded as constant. At the edge $R = a$. Anywhere in the shell $R = a$, corresponding with $n = n^\circ$, and the equation

$$w = A'e^{-n^\circ s}\cos n^\circ s \quad \ldots\ldots\ldots\ldots [19]$$

applies anywhere in the shell, since a and n° do not change with s. For the shell w is negative. The shearing force is given by the well-known relation

$$\text{Shear} = \frac{dM}{ds}$$
$$= \frac{Et^3}{12(1 - m^2)} \cdot \frac{d^3w}{ds^3}$$
$$= \frac{Et^3a_1n^{\circ 3}}{6(1 - m^2)} \cdot e^{-ns}(\cos n^\circ s - \sin n^\circ s) \text{ from [17]}$$
$$= \frac{Et^3a_1n^{\circ 3}}{6(1 - m^2)} \text{ when } s = 0 \quad \ldots\ldots\ldots\ldots [20]$$

This is for the knuckle at the edge. Using [19] there is found for the shell at the edge

$$\text{Shear} = -\frac{Et^3A'n^{\circ 2}}{6(1 - m^2)} \quad \ldots\ldots\ldots\ldots [21]$$

and since [17] and [18] both represent the shear at the edge, $-A' = a_1$.

Now collect from [3], [8], [18], and [19], and obtain

$$\left.\begin{array}{l}\text{Total radial deflection of shell at the edge } \dfrac{a^2P}{2Et}(2 - m) - a_1 \\ \text{Total radial deflection of knuckle at the edge } (R = a),\ \dfrac{a^2P}{2Et}(2 - a/r - m) + a_1\end{array}\right\} \quad \ldots\ldots [22]$$

These deflections must be equal, since the shell and knuckle do not separate. There thus is given $a_1 = a^2Pk/4Et$ if $a/r = k$.

For the knuckle, the bending deflection due to the shell-knuckle edge is, anywhere near the edge,

$$w = \frac{a^2Pk}{4Et}e^{-n^\circ s} \cdot \cos n^\circ s \quad \ldots\ldots\ldots\ldots [23]$$

and

$$\frac{d^2w}{ds^2} = \frac{a^2Pkn^{\circ 2}}{2Et}e^{-n^\circ s} \cdot \sin n^\circ s$$

The section modulus is $t^2/6$, so that the bending stress becomes, using [15]

$$S' = \frac{3a^2Pk\ n^{\circ 2}}{12(1 - m^2)}e^{-n^\circ s}\sin n^\circ s \quad \ldots\ldots\ldots\ldots [24]$$

or since

$$\frac{3(1 - m^2)}{a^2t^2} = n^\circ 4$$

$$S' = \frac{3Pk}{4n^{\circ 2}t^2}e^{-n^\circ s}\sin n^\circ s \quad \ldots\ldots\ldots\ldots [25]$$

for the head.

As already stated, [21] only applies near the edge for the head. To obtain an equation which applies for any distance s from the edge, the procedure is as follows: n is now a function of R. One can then write [24], for points close to the edge, as

$$S' = \frac{3a^2Pkn^2}{12(1 - m^2)} \cdot e^{-ns}\sin ns \quad \ldots\ldots\ldots\ldots [26]$$

which is correct when s is small and n differs very little from n°. When s is not small, one must replace ns by $\int n.ds$. There is also $\sqrt{3(1 - m^2)} = n^2Rt$, so that [26] can be written

$$S' = \frac{3a^2Pk}{4Rt\sqrt{3(1 - m^2)}}e^{-\int n.ds}\sin\left(\int n.ds\right) \quad \ldots\ldots [27]$$

Bending Hoop Stress. This is h/t, and it is seen from [12] that this is Ew/R, or Ew/a at the edge.

Substituting from [23] the hoop stress can be given as

$$H' = \frac{aPk}{4t}e^{-n^\circ s}\cos ns \quad \ldots\ldots\ldots\ldots [28]$$

close to the edge. Remote from the edge, Ew/R must be substituted in [23] and ns be replaced by $\int n.ds$. This gives

$$H' = \frac{a^2Pk}{4t\ R}\left(e^{-\int n.ds}\right)\cos\left(\int n.ds\right) \quad \ldots\ldots\ldots [29]$$

For the bending stresses set up by the knuckle-crown edge, Equation [22] becomes, using [8], [9], and [18] with $R = A$ instead of $R = a$:

Total radial deflection of crown at the edge,

$$\frac{PA^2}{2Et}(1 - m) - a_1$$

Total deflection of knuckle at the edge,

$$\frac{PA^2}{2Et}(2 - A/r - m) + a_1$$

Since these are equal, there is obtained

$$a_1 = \frac{PA^2}{4Et}(A/r - 1)$$

$$= \frac{PA^2K}{4Et} \qquad \text{if } A/r - 1 = K$$

There then are, for the stresses, remembering that s is now measured from the crown-shell edge, equations of the same form as [25], [27], [28], and [29], A being substituted for a and K for k.

The stress formulas derived in the foregoing are collected and arranged in Table 1.

Maximum Stresses

As will be seen from Figs. 1, 3, and 4, the meridional bending stress (due to the crown-knuckle edge) in the knuckle, is the most serious stress. This is S'' for the knuckle in Table 1. Considering the part of the formula $e^{-X} \sin X$, it is seen that this has a maximum value when

$$\frac{d}{dx}(e^{-X} \sin X) = 0$$

$$\cos X = \sin X$$

$$X = \frac{\pi}{4}$$

and the maximum value is

$$e^{-\frac{\pi}{4}} \sin \frac{\pi}{4} = 0.324$$

As this occurs near the shell-knuckle edge, one would be a little on the safe side in taking $R = a$, or

$$S'' \max = \frac{0.147\ PA^2K}{at} \qquad [30]$$

where $m = 0.3$.

By the same method the maximum values of S' for the shell and knuckle and S'' for the crown can be obtained.

The greatest value of the function $e^{-X} \cos X$ occurs when $X = O$, when the function equals unity. Consequently

$$H'' \max = \frac{PA^2K}{4at} \qquad [31]$$

with similar expressions for H'.

Membrane Hoop Stress. The greatest value of this occurs at the crown knuckle edge, and is

$$H = S(2 - A/r) \qquad [32]$$

Membrane Meridional Stress. The greatest value occurs when

$$S = \frac{PA}{2t} \qquad [33]$$

The foregoing maximum stresses are included in Table 1.

By taking the shell radius a as the value of R for the stress S' max in the head, the answer is a little too high. However, a stress of this amount must occur in the shell, since a is constant all over it.

The use of S'' max as the governing stress has already been discussed in the body of the paper.

Appendix No. 2

Best Shape of Meridian Curve Made Up of Two Arcs of Circles

THE maximum stress in any head whose meridian curve is composed of two arcs is

$$S'' \max = \frac{0.147\ PA^2K}{at}$$

and for any given (head radius) : (depth) ratio, or a/b, there can be an infinite number of such meridian curves.

If $r = 0$, there is obtained $A^2K = A^2(A/0 - 1) = \infty$

If $r = b$, A = infinity, there is obtained $A^2\left(\frac{\infty}{b} - 1\right) = \infty$

from which it would appear that somewhere between these two extremes there are values of r and A which make A^2K a minimum. This would give a head for which S'' max would have the least value.

Between A, r, q, and b, there is the relation (see Fig. 12-A)

$$(A - b)^2 + (a - r)^2 = (A - r)^2$$

from which

$$A = \frac{a^2 + b^2 - 2ar}{2(b - r)}$$

and

$$A^2K = \left[\frac{(a^2 + b^2 - 2ar)}{2(b - r)}\right]^2 \frac{(a^2 + b^2 - 2ar - 1)}{2(b - r)r}$$

Differentiating with regard to r, simplifying, and equating to zero, gives

$$2r(b - r)^2 + (a - r)^2(a - b)^2 - (a^2 + b^2 - 2ar)2ar^2 - (a^2 + b^2)(2r - b) = 0$$

Putting $b = ua$, this becomes

$$r^3 - \frac{a(5 - 2u + u^2 + 2u^3)}{2[1 + (1 - u)^2]} r^2 + \frac{a^2(2 - u + 2u^2)(1 + u^2)r}{2[1 + (1 - u)^2]} - \frac{a^2(1 + u^2)^2u}{4[1 + (1 - u)^2]} = 0$$

which is of the form

$$r^3 + C^\circ r^2 + C'r + C'' = 0$$

Put $r = X - C^\circ/3$. Then by the usual procedure for solving cubic equations, there are obtained

$$X = \sqrt[3]{g + \sqrt{g^2 - P^3}} + \sqrt[3]{g - \sqrt{g^2 - P^3}}$$

$$P = \frac{(C^\circ)^2}{3} - \frac{C'}{3}$$

$$g = \frac{-(C^\circ)^3}{3} + \frac{1}{2}C'\frac{(C^\circ)}{3} - \frac{C''}{2}$$

$$C^\circ = \frac{-a(5 - 2u + u^2 + 2u^3)}{2[1 + (1 - u)^2]}$$

$$C' = \frac{a^2(2 - u + 2u^2)(1 + u^2)}{2[1 + (1 - u)^2]}$$

$$C'' = \frac{-a^2(1 + u^2)^2u}{4[1 + (1 - u)^2]}$$

From these equations the knuckle and crown radii in Table 3 have been calculated.

Elliptical Heads. The meridian curve is continuous, so that only the shell-knuckle junction (stress S') has to be considered. S'' will not exist.

The radius of curvature of the ellipse at the junction is well

known to be $a/\underline{K}^2$ if $\underline{K} = \frac{a}{b}$. This is the r of Equation [22] which will read:

$$\text{Total deflection of shell at edge} = \frac{a^2P}{2Et}(2 - m) - a_1$$

$$\text{Total deflection of head at edge} = \frac{a^2P}{2Et}(2 - \underline{K}^2 - m) + a_1$$

From which

$$a_1 = \frac{a^2P\underline{K}^2}{4Et}$$

so that the equations in Table 1 hold for elliptical heads, $\underline{K}^2$ being substituted for k. As before pointed out, the expressions in K do not apply to elliptical heads.

Discussion

W. M. Coates.[3] The results which the author has obtained are rather surprising. The exception is that the method which he has used would show the discontinuity effects introduced by joining knuckle and crown to be of less consequence than those by joining cylinder and knuckle, especially if the head is of favorable form. The results of experiments also point in this direction, but inasmuch as the demonstration here is a purely theoretical one, it will be criticized on that basis. The explanation of the discrepancy between results and expectations lies in an incorrect application of the method.

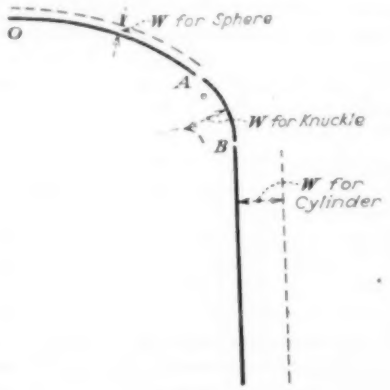

Fig. 14

To show this, consider the accompanying Fig. 14. The heavy lines show the meridional sections of the vessel, and are broken where geometrical changes occur in the nature of the shells. The dotted lines indicate to an exaggerated scale the normal displacements w in each part,[4] the magnitudes being laid off along perpendiculars to the contour. In the figure, the parts are considered as membranes under uniform inner pressure, stretched at their edges by the tensile forces necessary to maintain equilibrium. Then the first state of stress to be considered is the state in the membrane, given by the usual formulas for the case of cylinder and spherical cap. It is clear from the figure that in addition to this, a consideration must be made of the state of stress caused by the mutual restraints at points A and B which prevent the occurrence of the indicated discontinuities. This second group of effects is the one referred to as "discontinuity effects." There are very significant errors in the computation of both sets of effects in this paper.

Turning to Appendix No. 1, Equations [1] to [3] and [6] and [7] represent the well-known membrane formulas for the stresses and displacements, [1], [2], and [3] for the cylinder, [6] and [7] for the general curved shell. The last two hold for both crown and knuckle, the latter being the zone of a torus, starting from the equator.

Equation [8] represents the membrane normal displacement of the knuckle surface, but is true only for points on the equatorial circle. The correct value for points off this edge circle may be derived by the general method[5] and is very different from that given. To illustrate, the values of w at the top of the knuckle, point A in Fig. 14, are:

From data at bottom of third page	by Equation [8]	$-\frac{p}{Et}$ (9880)	error is approx. 70 per cent
	correct value	$-\frac{p}{Et}$ (5790)	
From data at bottom of fourth page	by Equation [8]	$-\frac{p}{Et}$ (11,970)	error is approx. 60 per cent
	correct value	$-\frac{p}{Et}$ (7450)	

The error in this expression is of fundamental importance, since w is used to determine the constants which enter the final expressions for the discontinuity stresses; see the work at the bottom of the eleventh page and the top of the twelfth page. It is much too high, as are also these stresses. Equation [30] is consequently incorrect, and the discussion which is based upon it in Appendix No. 2 and in the body of the paper loses thereby its significance.

It is to be regretted that the author has done so much work without proper study of the literature. This general method of attack will work if correctly applied; however, it should not be assumed that either its derivation or its application is new. Geckeler, for example, has given both in "Über die Festigkeit achsensymmetrischer Schalen," Forschungsarbeiten a. d. Gebiete des Ingw., V.D.I., No. 276. He uses a slightly different method of applying the boundary conditions at the junction of crown and knuckle.

In applying the method used in this paper, it should be kept in mind that the fundamental differential equation which is to give the discontinuity effects,

$$\frac{d^4w}{ds^4} + 4n^4w = 0$$

is strictly true only for the thin cylinder. However, it is approximately true also for the equatorial zone of the knuckle, if the thickness is not too great and the radius not too small. In going to the top of the knuckle, n is variable and the equations take the form of [27] and [29]. Although the author states these equations, they are not used, and additional errors are the consequence.

In comparing heads in the group of "favorable shapes," it must be shown that the small quantities neglected in the foregoing simplified form of the differential equation are of higher order than the differences to be expected between the results for

[3] Professor of Engineering Mechanics, University of Michigan, Ann Arbor, Mich.

[4] For the sake of the figure the values shown for w in the knuckle are made smaller than the actual ones, in comparison with those shown for crown and cylinder.

[5] See, for example, the reference quoted at the beginning of the paper, Höhn-Huggenberger, "Über die Festigkeit der gewölbten Böden," etc., part II, Equations [69a] and [69b], and note the misprint in the latter. This method applies also to the case of the cylinder, but is unnecessarily complicated there, and is generally replaced by that given in the paper, between Equations [2] and [3].

heads which are themselves only slightly different; otherwise the conclusions based upon the computation may give false testimony as to the actual state of affairs. Some discussion on this question has been given elsewhere.[6] The tangential displacement at the top of the knuckle, point A, should be investigated in connection with the determination of the constants of integration; also, the discontinuity hoop bending stress should be included among the stresses.

There are other points in the paper with which it is not possible to agree, but in view of the seriousness of those mentioned, it is not thought worth while to list more.

E. O. Waters.[7] Engineering practice with regard to pressure-vessel heads has passed through an interesting process of development. Starting with the flat head, it was realized at an early stage that a head of this form has no membrane strength whatever, and it has been abandoned for pressure-vessel use, excepting those cases, such as tanks for liquid storage, where the pressure is low and external reinforcement can be provided. Next came the spherical sector head with sharp knuckle; this had a membrane strength which was easily calculable, but it was obvious that it set up very severe stresses in the shell even if the junction between head and shell were assumed to be flexible; and, if the joint were not flexible, severe bending stresses were encountered in both shell and head in the vicinity of the junction. The first of these disadvantages led to the adoption of hemispherical heads, as in water tanks and steam accumulators, but that did not remove the second source of weakness, i.e., the bending stresses.

This condition was mitigated by the next step in development, the use of a knuckle having a small radius of arbitrary amount, together with a spherical crown, and more recently, the evolution of this type into (*a*) the spherical crown with large radius knuckle and (*b*) the full semi-elliptical head. Having reached this point, there may be some who have been misled into a belief that now we have only to design for the membrane stresses and the bending stresses will take care of themselves. To disprove this, one has only to study this very admirable paper, which shows that, as far as double-curvature heads are concerned, the critical stress exists near the shell-knuckle junction rather than in the crown where the membrane stress is the highest. This paper and a recent one by W. M. Coates, "The State of Stress in Full Heads of Pressure Vessels," (Trans. A.S.M.E., APM-52-12) are most timely in that they bring emphatically to the attention of American engineers a condition which, until recently, has received mention only in foreign literature.

Mr. Coates confined his analysis to elliptical heads, and in consequence his method of computing the boundary stresses is quite laborious; the present author has gotten around this by assuming the head to have constant radii of curvature, between limits. This raises the question as to whether the bending stresses at the edge of an elliptical head could not be computed by the method which the author gives for double-radius heads. Assuming that the radii of the ellipse do not vary greatly over the region in which the bending stresses exist, and assigning to them an average value in Mr. Rhys' formulas, results would be obtained with, perhaps, a sufficiently high degree of accuracy, and certainly with much less labor.

Both Mr. Coates and Mr. Rhys have emphasized the bending stresses near the junction of the head and shell. It is the writer's belief, however, that where the surface has a continuously varying curvature, these stresses may continue right up to the center of the crown and have a magnitude that is far from negligible. A series of strain-gage measurements on elliptical heads which he has observed during the past year has indicated that the apparent stress at the center of the crown is 5 to 10 per cent higher than the values obtained by the membrane formulas, and he is at a loss to explain them in any other way. The following analysis will throw further light on this question.

The meridional bending moment on an element of the head is (see W. M. Coates, loc. cit.):

$$M_1 = -\frac{Et^3}{12(1-m^2)}\left[\frac{d^2w}{ds^2} + \frac{m\tan\beta}{R_2}\frac{dw}{ds}\right]$$

where

E = Young's modulus
t = thickness of head
m = Poisson's ratio
w = radial displacement of the element
s = distance from the extremity of the major axis to the element, measured along the meridian
β = angle between the axis of the pressure vessel and a tangent to the meridian at the element
R_2 = radius of curvature of a section perpendicular to the meridian, at the element

The foregoing equation assumes that the displacement of the element under stress is purely radial. Precise calculation shows that this is sensibly true near the center of the crown; it is of course exactly true at the center. E.g., compare the values of u and w in columns 9 and 10, Table 1, of Coates' paper, for $\beta > 70$ deg. Then, from the relations (see W. M. Coates, loc. cit.):

$$w = \frac{R_2}{E}(S_2 - mS_1)$$
$$S_1 = pkav/2t$$
$$S_2 = S_1\left(2 - \frac{1}{v^2}\right)$$
$$R_2 = kav$$
$$\frac{ds}{d\beta} = R_1 = kav^3$$

where

S_2 = hoop stress on the element
S_1 = meridional stress on the element
p = fluid pressure per unit area
k = major axis/minor axis
a = semi-major axis
$v = 1/\sqrt{1 + (k^2 - 1)\cos^2\beta}$
R_1 = meridional radius of curvature

it may be shown that

$$M_1 = -\frac{(2-m)(k^2-1)}{24(1-m^2)}pt^2\left[\frac{k^2-1}{2}\cos^2 2\beta + (k^2+1-m)\cos 2\beta + \frac{k^2-1+2m}{2}\right]$$

and the bending stress at the outside

$$S_b = \frac{6M_1}{t^2} = -\frac{(2-m)(k^2-1)}{4(1-m^2)}p\left[\frac{k^2-1}{2}\cos^2 2\beta + (k^2+1-m)\cos 2\beta + \frac{k^2-1+2m}{2}\right]$$

When $m = 0.3$, $k = 2$, and $\beta = 90$ deg. (center of crown), $S_b = 1.96\ p$. Moreover, $v = 1$, and hence the membrane

[6] See the closure to the discussion of the paper, Coates, "The State of Stress in Full Heads of Pressure Vessels." Trans. A.S.M.E., APM-52-12, p. 130.

[7] Associate Professor of Mechanical Engineering, Yale University, New Haven, Conn. Assoc-Mem. A.S.M.E.

stress $S_1 = S_2 = pa/t$; accordingly, the bending stress is 196 t/a per cent of the membrane stress. For low pressures, where t/a is small, this may be an insignificant percentage; but for high pressure drums, where t/a is of the order of 1/20 to 1/10 or more, the bending stress appears to be far from negligible.

T. McLean Jasper.[8] The tests presented in this paper will add considerably to the knowledge of vessel phenomena dealing with riveted construction. The results indicate something of the real factors of safety which have prevailed in the past for such construction and will help to clear up the misconceptions which seem to prevail in the minds of a great number of engineers. It was the writer's privilege to obtain some of the original test results and to see some of the test work in progress. It is believed that the test specimens were prepared with great care and that the results were obtained with painstaking skill. It therefore should represent a very good picture of a type of construction which has given fine service over a great number of years.

May it be added that the stationary steam service, which has used this construction for a great number of years, has consistently designed on the basis of a factor of safety of 5. These tests therefore indicate very clearly the real factors of safety which have prevailed so far as heads are concerned, and are therefore exceedingly valuable contributions to the knowledge of vessels.

The thing which is very clearly brought out by this paper is that a dished head 72 in. in diameter, 2 in. thick, and with a knuckle radius of 7 in. failed at a hydraulic pressure of 1600 lb. per sq. in. With a uniform shell section of this thickness and diameter, the calculated stress at the failure of the head would be around (1600 × 72)/4 or 28,800 lb. per sq. in. The steel used is given a minimum specification strength value of 50,000 lb. per sq. in. The head undoubtedly failed when the stress reached the ultimate strength. The best that the writer can see to this head is that its value was not above 28,800/50,000, or 0.576 of what it should be for the cylinder providing a joint of 100 per cent could be made. It is presumed that the metal used had a strength somewhat above the minimum specification.

The writer ventures to state that today vessels can be constructed with joints as strong as the plate without increasing the thickness of the vessel section at the joint.

A second head with a knuckle radius of 6 in. and a thickness of 1.62 in. failed at a pressure of 1200 lb. per sq. in., or a calculated stress of 26,600 in the cylinder wall of the same thickness. This gives an efficiency for this head of about 53.2 per cent.

The third head, with a knuckle radius of 10 in., showed a value of 42,300/50,000, or 84.5 per cent. Undoubtedly this last head is as good as a riveted vessel with an 85 per cent joint efficiency needs. However, with no more metal, or at least very little more, an elliptical head can be constructed which will fail a vessel in the cylinder away from a properly constructed joint if properly attached.

May it be said that an elliptical head of 2 to 1 ratio when used with a riveted joint is so restrained at the joint by a double thickness of metal that it cannot develop the strength that it would develop with a vessel of uniform thickness at the joint.

The writer is sure that the author is in error when he states that the A.S.M.E. is well on the safe side with the elliptical heads recommended. They are just right in their recommendations for elliptical heads.

He wishes also to correct the impression that there is only one elliptical head design. Elliptical heads of 2 to 1 ratio will fail a cylinder wall of the same thickness if properly made and attached. An elliptical head of a ratio less than 2 to 1 will be even stronger, and such heads have been made on occasion for special reasons such as to avoid excessive reinforcement when openings are introduced into them, etc.

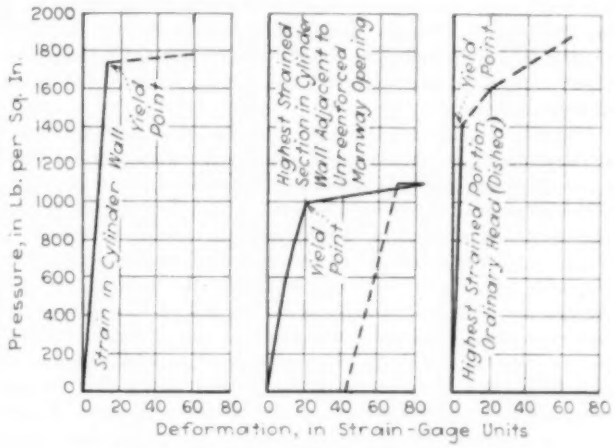

Fig. 15 Graph Showing Strain Values

(Given, under the same pressure conditions, in the main cylinder, at the most stressed situation around manway openings, and in the most stressed situation in a dished head. The yield point indicates when the metal has reached the same stress at each position where the strain measurements were made.)

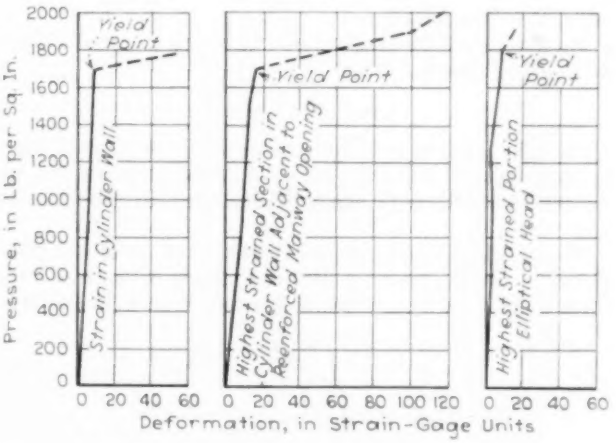

Fig. 16 Graph Showing Strain Conditions

(The appropriate conditions are shown when manhole openings are reenforced and when an elliptical head is used in place of the ordinary dished head.)

The writer desires to present Figs. 15 and 16, which indicate how a vessel design within the elastic limit of the steel behaves. These tests were made on a 72-in. welded vessel with 2-in. wall thickness and without a double thickness at the joint. The results on a large-radius dished head check very closely the author's results. The failure results on these tests checked the elastic results very closely.

D. S. Jacobus.[9] The paper is a valuable contribution, as it compares theory with experiment and shows the forms to be preferred in the construction of dished heads. The advantage secured by employing a longer knuckle radius than 6 per cent of the shell diameter, as specified in the A.S.M.E. Code, is brought out, and a statement is made that the A.S.M.E. specifications for elliptical heads are well on the safe side.

When the rules for dished heads were brought up for revision by the Boiler Code Committee, there was a desire on the part of a number of manufacturers to keep the knuckle radius as small

[9] Advisory Engineer, Babcock & Wilcox Company, New York, N. Y. Mem. A.S.M.E.

as practicable in order to use a flatter head than would be possible with a longer knuckle radius. The rules finally adopted called for heads with a knuckle radius of 6 per cent of the diameter of the shell and a thickness considerably greater than for elliptical heads. In the revised rules the knuckle radius was increased to about twice that formerly used and the thickness of the heads was also increased.

Professor Jasper has brought out an important feature—namely, that where the elastic limit of the material in the head is exceeded, the elastic formulas no longer hold. There are many designs based on the results secured in practice rather than on any particular theory; for example, in the case of a staybolted boiler, the structure should be strong enough to allow one of the staybolts to rupture without rupturing the others. If this feature were taken into account in the design of a staybolted structure and an endeavor were made to use an elastic formula and to keep within the working stresses, it would be found to lead to impractical results. Long use has shown that certain formulas give safe results for structures where the form is such that on exceeding the elastic limit at certain points there is an advantageous redistribution of the stresses.

In structures operated at the higher temperatures, where the effect of creep is the governing factor, the elastic formulas do not hold and the redistribution of the stresses due to creep is advantageous in all structures which tend to distort to a stronger rather than to a weaker form.

The author is to be congratulated on having prepared a useful and highly interesting paper.

Author's Closure

The principal criticism in the discussion by Mr. Coates relates to the validity of Equation [8]. The author presumes that the "correct values" given by him have been obtained in the following way:

The equations for determining displacement, [69a] and [69b], quoted by Mr. Coates in his discussion, appear in the paper "The State of Stress in Full Heads of Pressure Vessels" in the form,

$$\left.\begin{aligned} u &= \cos\beta \int^{\beta} \frac{\epsilon_1 R_1 - \epsilon_2 R_2}{\cos\beta}\, d\beta \\ w &= r\tan\beta + \epsilon_2 R_2 \end{aligned}\right\} \quad \ldots\ldots\ldots [20]$$

For a two-radius head R_1 would be the knuckle radius r, and R_2 would be given by the equation

$$R_2 = r + (a - r)\sec\beta$$

as shown in the Coates paper, at the top of page 10. ϵ_1 and ϵ_2 are the strains. By means of the usual stress-strain relations [21], the equations for membrane stress and the foregoing expression for R_2, the strains can be written as functions of β. Inserting all this in [20] and performing the necessary integrations, there results for the radial displacement,

$$w = \frac{Pr^2}{2Et} K \sin\beta \left\{ \tan\beta \left[2m + \frac{K^2}{3}(\sec^2 B + 2) \right] + K\left(m + \frac{1}{2}\right)\left[\tan\beta\sec\beta + \log(\tan\beta + \sec\beta) \right] \right\} + R_2\epsilon_2$$

where $K = a/r - 1$ and $m = 0.3$, Poisson's ratio.

From the data at the foot of the third page of this paper, there would be, at the knuckle-crown junction,

$$\sec B = 1.69,\ \sin B = 0.085,\ \tan B = 1.36,\ K = 4.15$$

and the quantity in the bracket above would become

$$1.36\ [0.6 + 5.72\ (2.84 + 2)] + 4.15 \times 0.8\ [1.36 \times 1.69 + \log 3.05] = 38.4 + 11.3 = 49.7$$

From the relations above, $R_2E_2 = \dfrac{PR_2}{2Et}\left(2 - \dfrac{R_2}{r} - m\right)$

$$= \frac{P}{2Et}(3136)(-6.3)$$

$$= \frac{P}{2Et}(-19{,}750)$$

and

$$w = \frac{P}{2Et}\left[49 \times 4.15 \times 0.805 \times 49.7 - 19750 \right] = \frac{P}{Et}(-5800)$$

which agrees closely with the result obtained by Mr. Coates.

When the membrane displacement of the crown is calculated, and the quantity a_1 is found from the bending and membrane displacements of the knuckle and crown (lack of space forbids giving this work in full), there results

$$a_1 = \frac{P}{Et}(3450)$$

and the bending stress becomes, for 400 lb. per sq. in. pressure, $\dfrac{P}{at}(2020) = 11250$ lb. per sq. in. There would also be a membrane stress of about 4600 lb. per sq. in. (using average of hoop radius R in knuckle), which brings the tensile stress up to 15,850 lb. per sq. in. It would appear that something should be added to this for the bending set up by the knuckle-shell discontinuity, though this may be dying away at the point considered.

In the list of stresses, see the second column on the sixth page, the stress governing design, calculated from the formula $S' \max = \dfrac{0.147\ PA^2K}{at}$ is given as 18,000 lb. per sq. in. Comparing this with the foregoing, it will be seen that results from the simplfied formula for practical calculation do not differ much from those obtained by the complete theory. As indicated elsewhere, Mr. McLean Jasper has found a correspondence with experiment.

The results given in the paper can be obtained without using membrane displacements.

At the crown-knuckle joint, the membrane hoop stresses, calculated from the dimensions of the knuckle and crown, respectively, are, by Equation [7],

$$\frac{PA}{2t}\left(2 - \frac{A}{r}\right) \quad \text{for } R = A$$

$$\frac{PA}{2t} \quad \text{for } r = R = A$$

If the head be considered to act as a membrane only, this would mean two different hoop stresses acting simultaneously round the crown-knuckle edge. Such an impossibility can be averted by bringing in the bending hoop stresses.

From [12] and [18] the bending hoop stress is, at the edge:

$$\frac{h}{t} = \pm\frac{Ea_1}{A} \text{ for the knuckle or crown, respectively.}$$

Then the total hoop stresses become, at the edge:

$$\text{For the knuckle } \frac{PA}{2t}\left(2 - \frac{A}{r}\right) + \frac{Ea_1}{A}$$

$$\text{For the crown } \frac{PA}{2t} - \frac{Ea_1}{A}$$

Equating these, and solving for a_1,

$$a_1 = \frac{PA^2K}{4Et} \quad \text{if } K = \left(\frac{A}{r} - 1\right)$$

This is the result given at the top of the first column of the twelfth page, from which the crown-knuckle bending stresses are obtained. The expression at the top of the second column of the eleventh page, for the shell-knuckle edge, can be obtained in the same way. In the foregoing no use has been made of expressions for membrane displacement.

The point brought out by Mr. Waters, regarding bending stresses near the center of the crown, is of great interest. As, however, they are relatively small as compared with those at the surface discontinuities, the latter would always govern design.

Mr. McLean Jasper mentions in his discussion the impression that there is only one elliptical-head design. The last paragraph before the Appendix, on the ninth page, to which this appears to refer, means that there is one ellipse for a given major and minor axis. It is gratifying to note the close check which he finds with the results given in the paper.

The discussion by Dr. Jacobus emphasizes the very important principle that a theory should be considered much more as a guide than a dogma. The author has tried to keep this in mind during the preparation of the paper, letting at least the general results of experiment be the determining factor.

Practical Application of Alloy Steels to Locomotives

By C. E. BARBA,[1] NORTH BILLERICA, MASS.

In the critical railroad situation, methods for reducing costs are important. The reduction of locomotive-maintenance costs by the judicious use of new ferrous-metal products is advised—those very products developed by steel-mill research for the industries aided by the railroads. The best of engineering practice should be applied to the design of built-up assemblies that will realize maximum strength and will reduce wear and tear of joinings, such as the integral bed frame for the locomotive foundation. The high initial cost of using nitrided steel and other special materials, as advocated in the paper, is expected to be justified by the reduced costs of maintenance and loss of service of locomotives.

ECONOMICAL and dependable transportation has been responsible in a great degree for our social, economic, and industrial development. For 75 years the railroads have provided such facilities, with only the competition of waterways and horse-drawn vehicles. For the last 25 years they have remained the main channel over which goods and people have been moved, but during this period the development of the automotive and the aviation industries has contributed in no small measure to the critical transportation situation now termed "the railroad problem."

The following discussion aims to focus attention upon the reduction of locomotive-maintenance costs by the judicious use of new ferrous-metal products developed by extensive research in the mills of the steel producers for those very industries built up by the railroads.

Carbon Steel

A special grade of plain carbon forging steel for heavy forgings, such as axles, driving rods, and equalizers, with rather close limits on carbon, manganese, and silicon, has been extensively used for a number of years. The degree to which this becomes a special steel rests with the customer, as to how narrow are the limits in chemical analysis he imposes upon the steel maker, and with the steel maker as to how much care and time he takes to produce a clean, sound material. More time in the furnace for refining and deoxidation adds to the net cost of the material, and the customer who buys the cheapest product will undoubtedly get the poorest product.

The chemical analysis of the ordinary carbon steel is generally within the following limits: Carbon, 0.40 to 0.55; manganese 0.50 to 0.80; sulphur, 0.04 (maximum); phosphorus, 0.04; silicon, 0.15 to 0.25. This steel is generally normalized and drawn after forging.

The following physical properties are representative of this material as heat treated: Yield points, 47,300; ultimate, 81,900; elongation, 25 per cent; reduction, 50 per cent; Brinell, 170; Izod, 10 to 20 ft-lb.

Carbon Vanadium

Modern locomotives brought about a demand for higher-grade steels. A carbon-vanadium steel was the next step in the forging-steel development. The chemistry of this steel is practically the same as the ordinary carbon steel, with the exception that manganese is increased and vanadium is added to show 0.15 to 0.18 in the steel. Vanadium in this amount helps as a scavenger to clean out the manganese oxides and iron oxides, and leaves very minute particles of finely divided vanadium oxide in the metal. These fine particles act as mechanical obstructions to prevent the growing of large grains in heating operations, producing a much finer grained steel than the plain carbon grade. It is generally stated by railroad men that their experience has shown that increasing the vanadium content above 0.25 does not improve the steel, and many go so far as to say that higher vanadium is even detrimental.

An average analysis of carbon-vanadium forging grade is as follows: Carbon, 0.50; manganese, 0.90; phosphorus, 0.030; sulphur, 0.040; silicon, 0.27; vanadium, 0.23.

The best practice on this steel has been found to be as follows: After forging, heat slowly to 1600 deg. fahr. to break up forging grain size; cool in still air; reheat to 1475 deg. fahr. to refine grain; cool in air; draw at 1100 deg. fahr.; cool in furnace.

The following are representative physicals after this treatment: Yield point, 58,000; ultimate, 105,500; elongation, 25 per cent; reduction, 54 per cent; Brinell, 185; Izod, 10 to 25 ft-lb.

These physical properties offered a distinct improvement over the plain carbon steel, and a large tonnage of carbon-vanadium steel has been applied to locomotives in the last 10 years.

Nickel and Nickel-Manganese Steels

About five years ago the need was felt for still better physical properties in the way of toughness and shock resistance. The nickel-manganese steel was the result of this search for better materials. Its production has steadily increased over the last four years as more railroads have specified its use in new engines and in repairs to existing locomotives. Nickel atoms displace iron atoms in the iron-space lattice and increase the toughness of the ferrite. Manganese is specified from 0.75 to 0.95, which raises the physical properties, while carbon is reduced to a range of 0.20 to 0.27, thus producing a steel with only half as much of the carbon—the hardening and embrittling element. The higher manganese neutralizes the effect of the lowered carbon and the nickel toughens the whole mass. The result is a steel that when normalized and drawn shows physical properties well up with carbon vanadium, but the ductility and toughness are very appreciably increased.

The following values were observed on a normalized and drawn piston rod, 5¼ in. in diameter: Yield point, 61,900; ultimate,

---

[1] Mechanical Engineer, Boston & Maine Railroad. Mem. A.S.M.E. Mr. Barba was graduated from Lehigh University in 1901, with the degree of Mechanical Engineer. His engineering activities have been equally divided between manufacturing and railroad engineering—in the former as superintendent of manufacturing enterprises and in the latter as draftsman to mechanical engineer. He studied manufacturing methods in England and Scotland and railroad practices in Germany.

Contributed by the Railroad Division and presented at the Birmingham Meeting, Birmingham, Ala., April 20 to 23, 1931, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

91,300; elongation, 28 per cent; reduction, 68 per cent; Brinell, 183; Izod, 90 to 93 ft-lb.

The Izod value or shock resistance of this steel is from five to ten times greater than carbon or carbon-vanadium steel.

The possibilities of this nickel-manganese steel, from the standpoint of heat treating to obtain higher physical properties and reduce the weight of moving parts, are just beginning to be realized. A $5^1/_4$-in.-diameter piston rod was water-quenched and drawn at 800 deg. fahr., and the following physicals were found in a test taken midway from surface to center: Yield point, 90,000; ultimate, 113,000; elongation, 23 per cent; reduction, 66 per cent; Brinell, 241; Izod, 92 to 95 ft-lb.

This high elastic limit with the high impact figure opens up the possibilities of weight reduction of reciprocating parts. A set of rods based on a 90,000 elastic limit, and calculated on the same factory of safety as a 45,000 elastic limit steel, would show a net reduction of 40 per cent in the weight of the reciprocating parts. When adopting this specification, it is necessary to redesign the rods so as to produce a full streamlined effect and get away from all short corner fillets and to use the thin-sectioned, wide and high I-beam section for the center parts of rods. A weight reduction of 40 per cent in reciprocating parts would be of incalculable benefit in the reduction of vibration, pound on rails, and in the bending moments on axles, which matters are at present receiving some attention.

Boiler Plate

Boiler plate for shells has been increased in strength by addition of nickel, and engines can now carry higher pressures without increase in shell thickness and boiler weight. Nickel-steel fireboxes are still in the experimental stage, some showing up well and others very poorly.

Chromium iron, with 18 per cent chromium, is under test for heat-resistant side sheets in fireboxes, and so far appears to be the answer to the fire and corrosion cracking experienced where engines are operated at a high rate of evaporation.

Wrought Iron and Steel

Low-carbon steels and irons are rapidly replacing the old wrought-iron staybolt. Canadian railroad operators have for nearly 10 years been using a low-carbon steel or ingot iron—on one road with a nickel content of 5 per cent and on the other of 2 per cent. The ingot iron with 2 per cent nickel is rapidly gaining on United States railroads.

Copper-Bearing Steels

Copper-bearing steel with copper up to 0.25 has many adherents as a staybolt material. Another type that is standing up well in service is an ingot iron with 0.50 copper and 0.10 to 0.15 molybdenum. The latter analysis is also used in heavy tonnage in the form of boiler tubes in stationary boilers and is proving very satisfactory in districts where corrosion and pitting of locomotive flues is a serious factor. For firebox plates in corrosive waters, it is showing definite superiority over ordinary steel plate.

Carburizing Material

A recent development in carburizing material suitable for case hardening in general use on railroads is the 2 per cent nickel iron. This material can be quenched in water direct from the carburizing pot and will always produce a hard case and a very tough core. Wrought iron is the only other iron that will do this. Steel invariably shows a brittle core when quenched direct from the carburizing pot. The 2 per cent nickel iron, for this reason, is distinctly a railroad material and has been developed as such, both for staybolts and for case-hardened brake rigging, spring rigging, and motion work pins. It has some application in the form of case-hardened liners for driving rods to protect them against wear from floating bushings.

Special Steels

In the matter of bolts used in frames and boiler studs, wrought iron grew up with the railroads, but increased stresses are gradually eliminating its use. The elastic limit of wrought iron is too low to carry the loads imposed upon it in modern locomotive construction, and when overloaded, it stretches, then becomes brittle (crystallized), and fails without stretching.

Wrought iron physicals are about as follows: Yield point, 35,000; ultimate, 48,000; elongation, 30 per cent; reduction, 40 per cent.

To replace this material for bolts subjected to nominal strains, we have turned to the S.A.E. 2115 analysis. This shows about 0.15 per cent carbon and 1.50 per cent nickel. It is generally found to show about the following physicals: Yield point, 43,000; ultimate, 62,000; elongation, 28 per cent; reduction, 65 per cent.

This analysis is doing very well when applied to boiler studs, cylinder studs, and frame bolts in the lighter engines; but there are applications requiring still higher physical properties, and these are met by using various analyses, such as S.A.E. 2320, 3120, 3130, 6130, and 1330 (carbon manganese), and the $2^1/_2$ per cent nickel-manganese steel used by one of the Canadian railroads. Chromium steel 5130 is used by one road in this country.

The general treatment is to quench the forged bolts or parts in oil or water and draw back to the required physical properties. The final properties are generally about as follows: Yield point, 90,000; ultimate, 105,000; elongation, 20 per cent; reduction, 60 per cent; Brinell, 225; Izod, 50 to 70 ft-lb.

The following parts are often made from the foregoing steels: Superheater bolts, cylinder bolts, frame crosstie bolts, binder bolts, coupler bolts, piston keys, driving-rod collars. Many other applications have been found where a heat-treated alloy analysis will stop breakage and renewal of parts.

Nitrided Steels

About the last word in the steel world are the special steels that have been produced to use in applying the super-hard cases that are built up by heating the finished parts in ammonia gas. These are known as nitrided steels.

The ammonia gas dissociates into nascent nitrogen and hydrogen at about 850 deg. fahr. The parts to be hardened on the surface are first formed, then heat-treated, and then finish-machined, ground, and polished before placing in the retort for nitriding. The nascent nitrogen at 925 to 975 deg. fahr. combines with the iron, chromium, and molybdenum in the steel to form nitrides of these elements, and these nitrides form the hardest wearing surface that science has been able to develop, excluding the carbide cutting tools. It has been known as early as 1907 that nitrogen would, under certain conditions, combine with iron to form iron nitrides and that these iron-nitride grains were exceedingly hard. But the hard cases formed were brittle and spalled off from the base metal easily.

Various investigations worked to bring out steels that would form tougher cases with nitrogen. The result has been a steel containing chromium, molybdenum, and aluminum. The chrome and molybdenum toughten the case, and the aluminum acts as a catalyzer and stabilizer to maintain the high surface hardness. The steel is produced in four carbon ranges, running as low as 0.12 to as high as 0.65.

The heat treating and machining are all completed before the hardening operation, and that is conducted at low temperatures, 950 to 1075 deg. fahr., so that distortion and subsequent grinding are eliminated and parts may be machined to very accurate di-

mensions or fit and then hardened with little danger of warping.

This case is the hardest and most uniform structure ever produced on steel, and as such its great wear resistance is opening up undreamed-of possibilities of long-lived parts for locomotives.

The basic idea in the application of nitrided steels to locomotives is to select for its application those parts in which frictional wear causes heavy expense for renewals.

The fundamental law in bearing metals is that if the two parts are of equal hardness they will both wear. If one is hard and the other soft, the softer will take the greater wear.

In applying nitrided steel the endeavor should be to replace those parts that are most expensive to replace and to throw the wear over on the least expensive part.

Where a rotating shaft or pin is to be considered, it is generally cheaper to make the bushing take the wear.

The metallurgists have some restrictions as to microstructure, effects of time and temperature, gas pressure in retorts and their effects on the hardness, depth of case, toughness, etc., but the mechanical engineer is mainly interested in two things:

(1) Can wear be reduced without sacrificing strength?
(2) Will the increased life of wearing surface compensate for the higher cost of the material used?

In preparing a wearing surface of nitrided steel one must remember that he is dealing with a surface hard enough to cut glass. Nitrided wearing surfaces must be lapped in or polished, or glazed, before the nitriding treatment is applied. After the nitriding it is too hard to do much with, and furthermore the best wearing part is on the surface, and grinding after nitriding is considered detrimental and as poor practice. As to the selection of bearing metals to be used against nitrided surfaces, this is of vital importance. New and harder bearing metals are being used with great success. Any application of nitrided steel should also be considered from the standpoint of the bearing metal to work with it, and the men who are building up test data and experience should be consulted.

Theoretically, all moving parts should be on a par with each other as to wear-resisting qualities, so that the weakest link, all other things being equal, in the maintenance and replacement of parts becomes the locomotive tires.

The service life of wearing details by the judicious selection of materials and improvement of design to best utilize these materials then becomes a multiple rather than a fractional part of the tire-service l fe.

The following parts in the running gear of a locomotive are enumerated in the order in which renewals due to wear take place: Piston rings, valve rings, cylinder bushings, valve-chamber bushings, piston heads, piston-valve parts, piston rods, valve rods, valve crossheads, crosshead shoes, guides, valve-motion pins and bushings, valve links and blocks, locomotive tires, trailing-wheel tires, crown brasses (driver box), hub face (driver box), side-rod bushings, wrist and knuckle pins, crankpins, shoes and wedges, driving axles, hub of driving-wheel centers, hub of trailing-wheel centers, hub of engine-truck wheels or centers, swing-motion details of engine truck, spring-rigging details.

Similarly, the boiler may be subdivided into the following renewable details: Grates and appurtenances; firebox sheets, side, crown, back, and flue; tubes and flues; staybolts, rigid and flexible; superheater, header and units; exhaust nozzles; smoke-box netting.

In order to illustrate just what can be accomplished, it might be well to start at the power end of the locomotive, the cylinders, and analyze conditions.

Locomotive cylinders are bushed with cast-iron bushings as a means of preserving the cylinder and saddle throughout the life of the locomotive. Cast-iron cylinder bushings of refined iron are undoubtedly the best practice developed through the years, but due to the unsupported piston, the bushings will wear out of round and in time must be rebored. The same thing holds true of the piston, or of the composite type, the bull ring, which obtains a similar wear and must be built up or replaced with a new one.

This, however, requires dismantling of the cylinder heads, piston, etc., and the tieing up of a locomotive, and it would seem rational to assume that if the present bushings were replaced with nitrided-steel bushings, having a hardness equal to 850 to 950 Brinell, lapped to a very high polish, the hardness would never be disturbed, as the range of temperature is well within that used for nitriding purposes. The same holds true for piston-valve bushings.

Such an installation would undoubtedly mean the elimination of future rebores and the prevention of leaks past the snap rings, thereby conserving steam.

Proposed Manufacture of Cylinder Bushings

The development of nitralloy cylinder bushings, other than forgings, presents a most interesting problem in that plate can be used by rolling into shape and welding by the atomic-hydrogen-arc process, after which it may be machined to size, bore-lapped, and nitrided prior to application. The following methods are used: (1) Welding of $1^1/_4$-in. thick plate; (2) heat treatment of welded assembly; (3) machining and nitriding of welded assembly.

The work was undertaken with an objective of forming large cylinder bushings for locomotives. The bushings were to be made

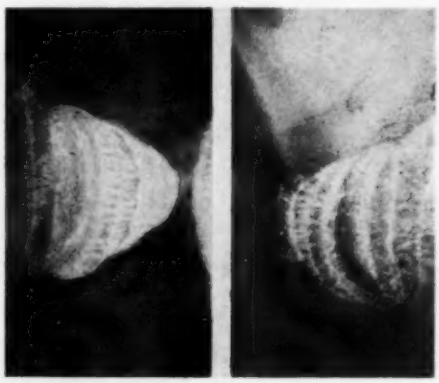

Fig. 1 Microphoto Through the Case
(At left, through the weld after heat treatment; at right, across the weld.)

of $1^1/_4$-in. plate rolled into cylinders, welded, heat-treated, machined, and then nitrided.

After two or three trials the proper technique was developed, and several welds free from blowholes were made. Chemical analyses of the wire used and the plates and welds were as follows:

	C	Cr	Al
Welding wire.....	0.256	01.42	1.13
Plates welded.....	0.26	01.21	0.95
Weld No. 1.....	0.122	01.32	0.86
Weld No. 2.....	0.178	01.30	0.86
Weld No. 3.....	0.139	01.35	0.82

The three welds shown averaged about 10 points less carbon and 27 points less aluminum than the original analysis of the rod. The plates had about the same carbon content as the rod. The aluminum remaining in the welds is well above the 0.60 per cent minimum required to produce a proper case. The drop in carbon is really beneficial, as the weld is more ductile than if the carbon was all retained.

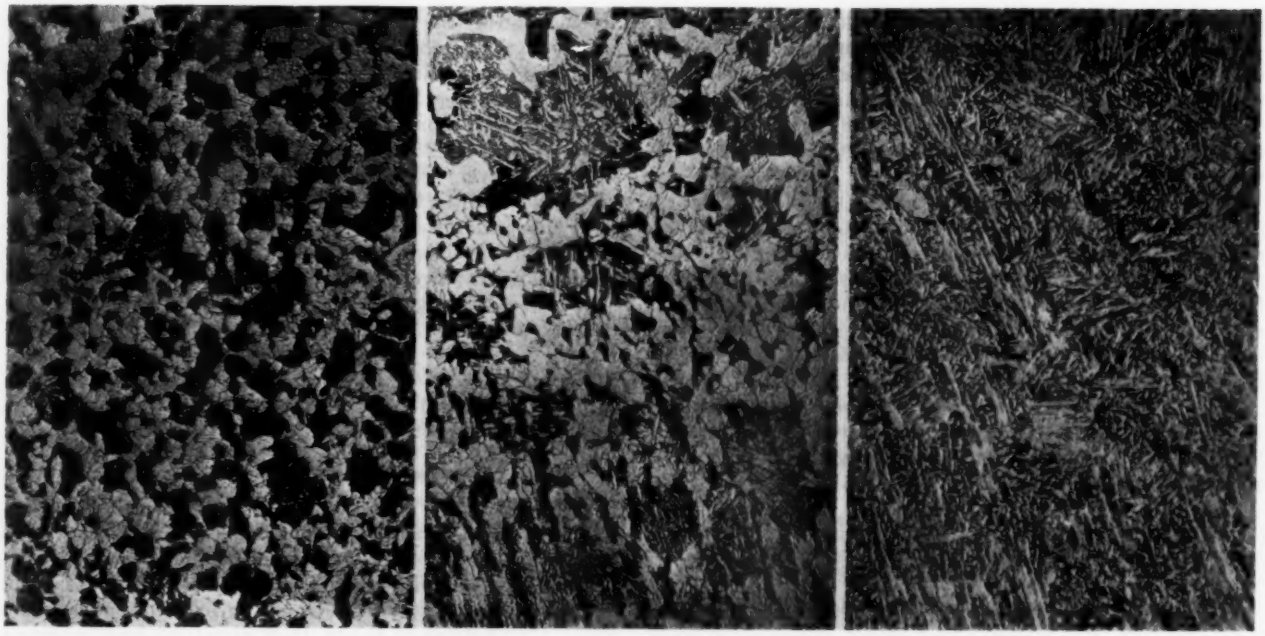

FIG. 2 MICRO-STRUCTURES AS WELDED × 100
(At left, parent plate; in center, weld junction; at right, welded metal.)

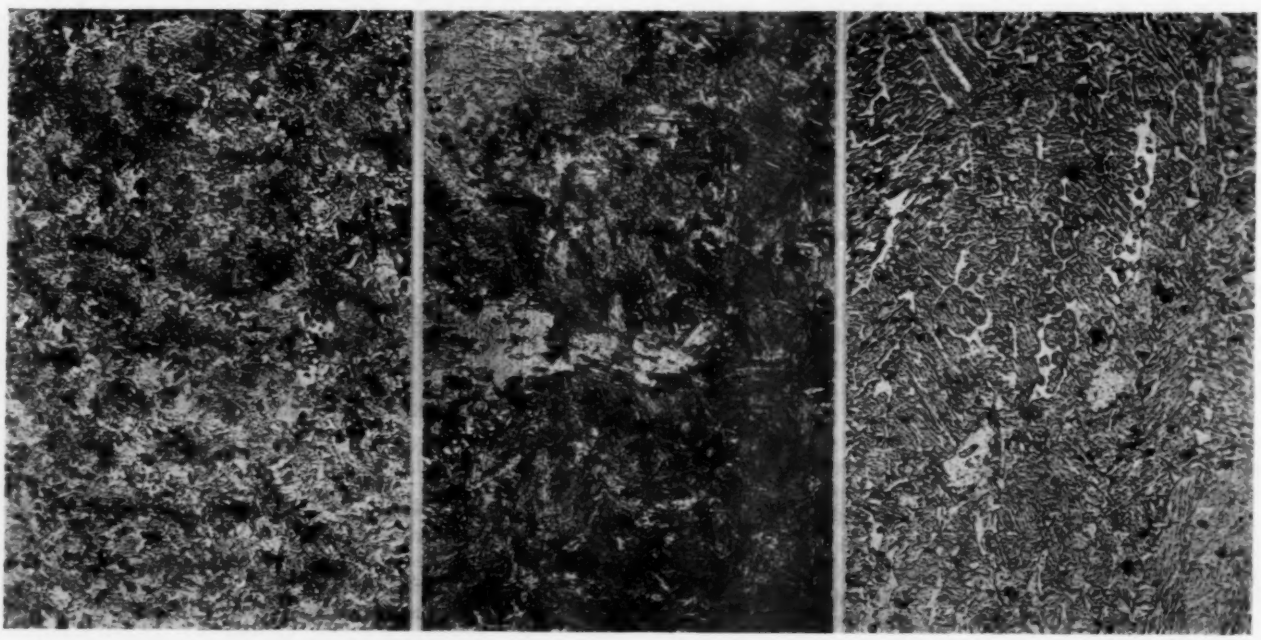

FIG. 3 MICRO-STRUCTURES AS TREATED × 100
(At left, parent plate; in center, weld junction; at right, welded metal. Water quenched at 1700 deg. fahr.; drawn at 1325 deg. fahr.)

A section about 6 in. long with weld running full length of it was heat-treated, 1700 deg. fahr. in water and 1325 deg. fahr. in air, machined from $1^1/_4$ in. thick down to $^3/_4$ in. thick, ground on both flat surfaces, and then nitrided for 42 hours at 925 deg. fahr.

Hardness readings showed around 850 to 900 Vickers Brinell. No difference was apparent between the readings on the welds and those made on the parent stock.

Micro-section through the case showed the same penetration on weld as on parent stock. Microphotos, Figs. 1 to 5, show the various structures.

The atomic hydrogen process can be used successfully to obtain welds of special steel analysis that will produce a nitrided case identical in hardness and micro-structure with the parent metal.

There are dendritic structures retained in the welds that might be broken up by forging, but are not thought to be detrimental where the bushings are under no particular strain and are only applied to obtain a surface for resistance to wear of piston and rings.

The success of the operation is entirely dependent on the skill and art of the welder, and a policy of rapid fusion and the application of small drops of molten metal at a time must be observed. Puddling the metal will invariably cause excessive loss of aluminum and will develop blowholes in welds.

The utilization of special steels and the engineering problems in connection therewith are outlined for various locomotive details as a means of stimulating the art.

Piston Heads and Rods

The piston head, irrespective of design, can be made of a special steel forging or casting and the rim be nitrided after grooves have been machined and lapped to dimensions, so as to eliminate groove wear from snap-ring action; likewise piston-valve parts.

With respect to snap rings, these can be made of a bronze alloy, L-shaped, capable of sustaining temperatures from 900–950 deg. fahr., without removing the snap, which, in contact with a highly polished surface of extra hardness, is bound to give maximum life, as well as that of the piston head.

The possibilities of the use of an extended piston rod should be given further consideration, as the conventional design now in use cannot be sustained as one in which the best of engineering principles have been incorporated.

The weight of the piston should be supported at the rear by the crosshead and at the front by a pivoted bearing for alignment, which undoubtedly would minimize or practically eliminate the wear of the piston-rod packing and the circumferential wear of the piston head, and simplify the work of the snap rings, since we are starting out with a true bore lapped for accuracy and hardened. The only compression variable of the rings would be that created by the vertical and lateral wear of the crosshead.

The extended piston rod is not a new idea, but its abandonment from general use was largely due to the inability of controlling the wear between crossheads and guides, both vertical and horizontal, within limitations which would not affect the bearing surface of the extended piston-rod crosshead, or support, at the front end of the cylinder.

The adoption of nitrided steel for piston rods the wearing surface of which can be hardened so as to eliminate wear should prolong the life of the piston-rod packing, as it is certainly less expensive to replace rings than it would be to grind down piston rods.

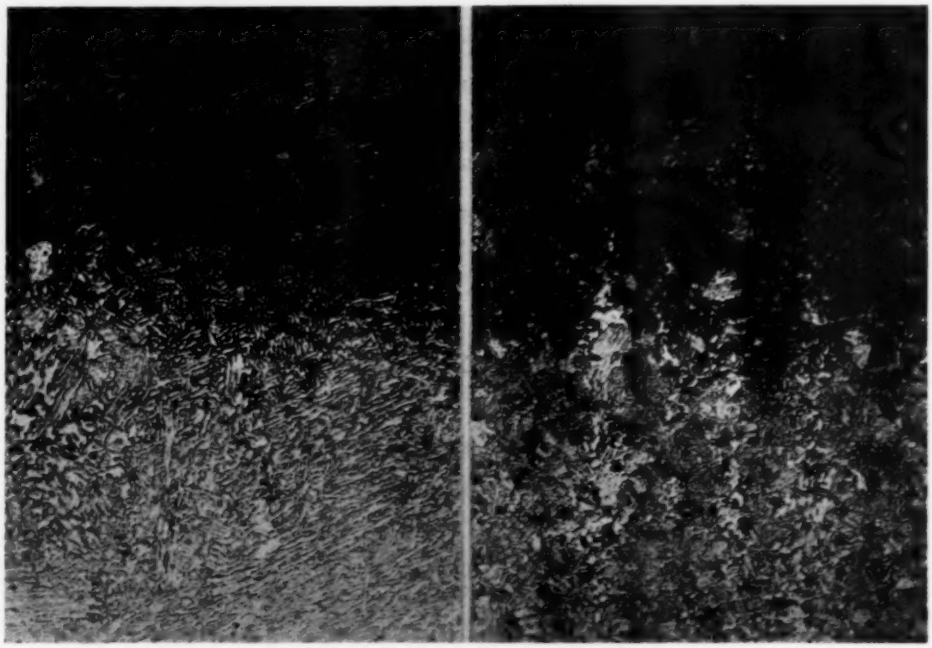

Fig. 4 Nitrided Cases
(At left, welded metal; at right, parent plate.)

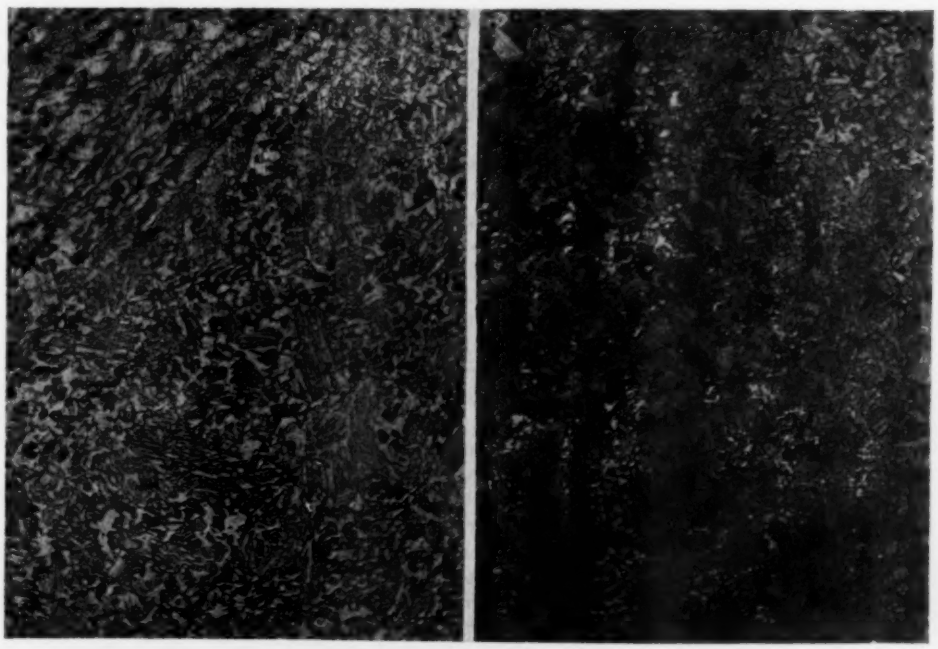

Fig. 5 Core Structures
(At left, welded metal; at right, parent plate.)

Crosshead Shoes and Guides

In the case of crosshead shoes and guides it is considered best to apply nitrided plates to the guides and to apply bearing metal to the crossheads or crosshead shoes in the form of channels,

which can be quickly removed and replaced at very low cost. The present practice calls for removal of worn guides and building them up with welding bronze; then they go to the blacksmith shop to be annealed and straightened, then to the planer and the surface grinders and finally back to the engine, where they must be reset. Generally the boltholes all have to be reamed again and new bolts fitted, so that rehabilitating a worn crosshead guide becomes an expensive job.

The proper selection of steel for controlling the wear of crosshead shoes and guides, or the designing of either on the basis of increasing the bearing or pressure area, thus reducing the pressure in pounds per square inch to a minimum and thereby increasing its life, or the utilization of a special steel and maintaining the present bearing areas, should assist in reestablishing a design of paramount importance in the reduction of maintenance.

As a matter of fact there is no reason why guides and crossheads should not be capable of operating 150,000 miles without the necessity of a take-up during that period. The wear of guides is partly due to having a piston hanging at the end of a rod one end of which is fastened to the crosshead, very much out of balance and ready to drop in its movement equal to the difference in diameter between the piston head and the bore of the cylinder, the tendency of which is to cock the crosshead at the end of the stroke.

Side-Rod Bushings

Side-rod bushings have ever been a source of trouble due to rapid wear. The selection of bearing metals is a matter of utilizing a bronze that can be subjected to a higher working temperature than is now possible, and when used in connection with hardened crankpins the wearing qualities can be increased, while seizure from operating temperatures and lack of proper lubrication will be practically eliminated.

Driver Boxes

Driver boxes as designed at present have not sufficient sustaining qualities for the application of a pressed-in crown brass, due largely to the limitations of present pedestal spacings, all of which can be modified by the elimination of shoes and wedges.

The present use of shoes and wedges is to take care of wear of the box, liners, and shoes. To minimize this wear, so that they will operate between shop repairs within the tolerances prescribed, will necessitate the use of nitrided-steel wearing surfaces. Furthermore, the use of shoes and wedges ofttimes creates improper transverse alignment or parallelism of driving axles, which, if elminated, simplifies shop operation.

The design of the box could therefore be modified by utilizing a portion of the thickness of the present shoes, wedges, and floating liners by increasing the over-all width. The wearing surface of the driver boxes and pedestal fit should be a flanged liner, on both pedestal and box, made of manganese steel not less than $^3/_{16}$ in. thick, the life of which should not be less than 200,000 miles.

Such a design would permit the use of a crown brass, more rugged in design, and which can be applied without pressure, so that replacement is simplified and present costs minimized.

The ever-increasing lateral between driver box and wheel hub can practically be eliminated by the application of nitrided-steel liners inserted into a recess in the hub of the driving wheel and welded on the periphery, in conjunction with a similar liner inserted in the face of the driver box, the hardness of which should be approximately 850 to 950 Brinell. Such liners, when coming in contact, either lubricated or non-lubricated, should be good for 200,000 miles.

Driving Axles

Locomotive-axle failures are an increasing difficulty and expense. There are two types of failures. The one type is a fatigue crack starting in the fillet next to the wheel center. This type of failure generally starts in a rough finished fillet or where the brass cuts a shoulder in the fillet. Anything that will produce a notch effect on the bearing surface of the axle will start a crack that will progress until the heavy starting torque and the bending moment on the axle, when the crankpin passes over the center, will produce enough strain to rupture the remaining portion. The second type of failure is that of hot boxes, which produce thermal checks on the journal surface, and these are starting points for progressive fractures.

Anything that would relieve the axle of the duty of supplying a wearing surface as well as resisting the high fiber stress due to flange pressures would prolong the life of the axle. Axle bushings of nitrided steel, shrunk on the axle, are now being tried out in testing laboratories.

Furthermore, there is no reason that a pair of wheels, when mounted, should have journals re-turned so as to true up the wear or abrasion; as with a pair of driving-wheel centers, properly mounted on a nitrided-steel axle and having journals hardened or bushed together with nitrided-steel crankpins, properly quartered, the unit as a whole should give a maximum life and should never be disturbed exclusive of the replacement of tires.

Locomotive Links and Motion Parts

Locomotive links, the design of which has not been altered for many years, require continual regrinding, due to the movement of the block, but if made of nitrided steel, regrinding can be eliminated if used in conjunction with a hardened block having a Brinell of 500 to 600.

When one considers the importance of proper steam distribution, the ideal valve motion, irrespective of type, would be one in which all parts would never require any adjustment due to wear of pins and bushings. Here again the utilization of nitrided steels will go a long way toward establishing a greater degree of accuracy and more perfect steam distribution than is now possible.

Spring Rigging

The function of a spring rigging is one to take care of track irregularities, tire wear, etc., and the proper distribution of weights on the running gear. Consequently, spring design and the materials selected play a most important part. The gradual elimination of the present elliptic spring and the adoption of a different form of spring suspension than used at present, together with a redesign of hanger that will produce minimum wear and preserve the alignment of locomotive, irrespective of tire or crown-brass wear, is in order.

There is no good reason why the designing and manufacturing of locomotive springs should not follow automotive practices, due to their widespread application and their varied services.

From the foregoing it will be observed that there is opportunity for radical departures from present-day practice; but unless those directly interested in engineering principles covering locomotive design change their viewpoint in the utilization of ideas and materials used so successfully in other lines of industry, we will be unable to profit from the progress which has been made in those industries for our own use, as a possible means of decreasing maintenance.

Firebox Steels

The major problem in the selection of steel is one of temperature, and naturally a steel is required that will resist whatever the maximum temperatures of a firebox may be (under various operating conditions) so as not to break down the structure of the material. This in itself is quite a large contract, and various

grades of steel have been tried with varying results, but not with sufficient assurance that their adoption would eliminate all of the troubles now experienced. It would therefore appear that one of the major problems is one of design, in which the flow of gases over the arch will be similar to the flow of water over a dam—that is, straight-line movement. The influence of the draft-producing medium at the center of the smokebox undoubtedly causes a stream flow of the gases converging toward that center, thus materially lessening gas flow and heat transfer away from the center of the tube sheet, all of which has a tendency toward creating hot spots in the firebox rather than maintaining a uniform temperature throughout.

Furthermore, the percentage of carbon in firebox sheets is believed to require careful consideration and should be a minimum, and excluded if possible, as any unnatural carbon content must have a hardening influence when heated and cooled, sometimes abruptly, under the present operating conditions. Experiments are now being conducted on a brick side-wall lining to determine the effect of controlling the rapidity of temperature change by a more uniform heat distribution.

Grates

The design of grates and the selection of a material that will resist heat at higher temperatures than any material now in use would be a step in the right direction, although a grate may be so designed that its section may be sufficient to reduce the temperature at the top of the grate, well within the confines of the critical range of the material, by the net area and distribution of the air inlets. This, however, requires some experimentation to determine.

Staybolts

Design likewise should more fully enter into the final analysis of the staybolt rather than the mere selection of better material, or type of material, as steel versus wrought iron. The entire firebox (were it not for the attachment of the firebox sheets to the mud ring) is a floating chamber supported by staybolts. The water legs, increasing in width from the mud ring to the crown sheet, with the space between the crown sheet and the wrapper sheet being in excess of that of the widest width of the leg, calls for staybolts of varying lengths, but practically all having the same diameter.

Considering the staybolt as a cantilever beam—that is, by assuming that there is no movement of the wrapper sheet relative to the firebox sheet—the number of pounds required to deflect a long staybolt is naturally less than that for a short staybolt having the same diameter. Consequently there are zones in each firebox side sheet that are restrained due to the constant force of expansion at uniform temperatures, by the shorter bolts not deflecting the same amount as the longer ones, which produce strains within the sheets that in time will produce hairline cracks around staybolts, and eventually failures will result.

As a suggestion why not divide the application of staybolts in a vertical plane into horizontal zones and design the staybolts in certain zones according to their length by assigning diameters so that all staybolts may deflect in unison, assuming that the expansion force is constant. Undoubtedly an application of this character might show some very interesting results.

Wheel Centers

The design of wheel centers and the character of steel used is a subject that, in the author's estimation, requires more research. Taking a concrete example, specifications require that all steel castings must be annealed so as to relieve strains introduced during cooling. This seems to be general practice.

On the other hand, the practice is to take a wheel center, press it on an axle, introducing compressive strains in the hub which may or may not be transferred to the spokes, and then press in a crankpin, the stresses of which go into the hub and spokes, and finally shrink on a tire, which not alone compresses the rim but likewise the spokes, and the result is a wheel center having all sorts of internal strains. As a matter of fact, it is strained far in excess of any strains that may have been introduced originally during the casting and cooling process, and still it is insisted that those strains must be removed and nothing is said of the strains of the completed article.

It would therefore seem that tests are in order calling for the application of extensometers on spokes, hubs, and rims, covering all of these operations for the determination of stresses or for the possible redistribution of metal if it is found necessary, to take care of these strains, which should assist in furthering the life of the present wheel centers.

Locomotive Tires

Present practice in locomotive tires, or for that matter in any tired wheel, irrespective of size, calls for three grades of material—that used in passenger, in freight, and in switcher service—representing graduated increases in carbon content and consequently hardness to resist wear. These materials have undoubtedly stood the acid test for many years. There is a question, however, with metallurgical engineers as to whether the railroad engineering profession has not overstepped its limits with respect to wheel loads, taking into consideration the small contact area that a tire makes with the rail.

This subject undoubtedly covers a great many years of intensive research, primarily metallurgical, but limited in engineering considerations, as mass has not been considered an important item where fluidity of metal (due to great pressures) is concerned. It is believed that better results could be obtained by increasing the thickness of a tire over the conventional thickness so as to have more backbone in assisting the transmission of weight to the rail, and naturally giving more resistance to wear on account of this additional thickness.

Toughness in tire materials is a determinant in wear resistance, but unfortunately in ordinary tire steels toughness is obtainable only by increasing the carbon content, which produces a material of improved wearing characteristic but of a hardness with increased tendency to fracture under shock stress. However, with the change in speeds of freight locomotives narrowing the gap differentiating from passenger-operating characteristics, it is felt that the harder B-grade tires can be used for all A-grade purposes.

Further, to meet the demands of maximum hardness and for high tensile and elastic limit to resist flowing tendencies under heavy wheel loads, and to advance the service life of tires to meet the possibilities of increased life in other wearing parts, considerable attention should be given to alloy-steel development for tires. Tires are now being used with nickel and manganese content, giving harder wearing surfaces without the brittle tool-steel characteristics of high-carbon-content tires. The surface as yet, however, has only been scratched.

Tank Steel

The selection of materials likewise can be extended to the use of tank sheets instead of the present open-hearth steel. Even though copper-bearing steels are being used to a very large extent, other materials can be procured in which corrosion can be eliminated, and therefore the initial cost can be justified, considering the elimination of tank repairs which are now prevalent.

It also would be helpful in designing the slope sheets to have the joints made on the vertical sides instead of where the slope sheet coincides with the side sheets, and providing at least a 6-in. or 9-in. radius in the corners, not alone to assist the coal in

passing to the conveyor more freely, but likewise preventing the corrosive elements from entering the joints made in present-day construction.

The utilization of alloy steels is not the only attack on maintenance. The best of engineering practices and the industrial arts must be drawn upon in the development of integral designs to replace built-up assemblies for the purpose of realizing maximum strength and reducing wear and tear of joinings. This is strikingly exemplified in the design of the integral bed frame for a locomotive foundation.

This represents a radical and bold departure from past practices; yet experience has now been of sufficient length amply to justify the design.

It is believed that the money expended for the initial cost of using nitrided steel and the other special materials referred to, as a means of decreasing maintenance, will be more than justified in the subsequent reduction in maintenance cost and lesser loss of service of locomotives due to required maintenance.

An accounting system should, if necessary, be developed by which the cost of repairs or replacements of individual details of each class of locomotive can be recorded for easy reference and to serve as a source of reliable reference data.

In conclusion it might be well to emphasize the wonderful possibilities in design in conjunction with the utilization of high-grade material which the railroad engineering profession should consider; as the selection of steels to cure all evils that may predominate is only a portion of the problem. Unless the engineer and the metallurgist exchange ideas more freely as to requirements due to present operating conditions, in order that maintenance may be reduced lower than it ever has been in the history of railroading, the advancement of locomotive design will not progress any more rapidly than it has in the past.

The author is greatly indebted to the efforts of the Republic Steel Corporation, through its able assistants Messrs. Morris and Miller, of the Metallurgical Department, for the development of various applications of nitrided steels for locomotive use.

Appendix

INFORMATION TRANSMITTED BY AUBERT & DUVAL, OF PARIS, FRANCE, ON THE REQUEST OF DR. ADOLPH FRY, OF THE KRUPP WORKS, ESSEN, GERMANY

Nitralloy has been used successfully in locomotives for crankpins for driving and for coupling. Some of these pins have been in service for seven years without showing any wear.

A noteworthy fact is that the wear of the bearings has practically stopped on locomotives so equipped; heretofore, when case-hardened pins were used, bearings had to be replaced at least four times a year. During a much longer period of time in using nitralloy, no replacements were necessitated.

On a locomotive of the Deutschen Reichbahn pins have been in service for 350,000 kilometers, or approximately 262,500 miles. These pins showed some wear in places, which necessitated grinding; after grinding the pins were re-nitrided and put back into service, and they gave complete satisfaction.

Nitralloy is also used with success for different parts of the poppet valves of the Caprotti type now being used to replace slide valves. In a poppet the rods, cams, guides, etc., undergo considerable wear, resulting in an ordinary steam loss of about 3 per cent. Tests made to date using nitralloy for these parts seem to show that it eliminates all wear, with the result that there is little or no loss of steam.

Several tests are now being conducted using nitralloy crosshead guides. These tests have not been completed, so that no report can be made at the present time.

Discussion

HOWARD L. MILLER.[2] The intense heat developed by stoker fires of locomotives and the oil-burning locomotive within the past three or four years has proved to be beyond the capabilities of ordinary steel. Firebox renewals have been increasing at a very rapid rate. The main difficulty seems to be in the side sheets, which are exposed to intense heat under the brick arch. This type of failure is distinguished by cracks running from the staybolt holes, mainly in a vertical direction. The rapid rise and fall of temperature in the firebox due to stoker fire is responsible for this type of fatigue failure.

The antidote to this trouble has been proved up in service, and the 18 per cent chrome iron with carbon under 0.10 per cent and silicon around 1 per cent, known as Enduro type A, such as is used for nitric-acid tank cars, has proved to be able to withstand the terrific heat to which the side sheets of the firebox are exposed. This material has a very low coefficient of expansion throughout the range of temperatures involving service and shows about two to three times the creep limit of common steel in the service temperatures of firebox plate. It is also practically non-corrodible as regards boiler water. This material can be welded to common firebox plate using a coated common steel wire.

J. H. HIGGINS.[3] Much success has been achieved during the past 15 years, and the manufacturer feels no little pride in the part he has taken in these improvements, for there has been close cooperation with the mechanical engineer and an earnest endeavor to work out and improve locomotive equipment parts.

The author has covered the progressive steps from carbon steels into the alloy steels, and while these steps have materially reduced failures, some still occur both by wear and fracture, so that we are compelled to continue our experiments along the lines of recent metallurgical discoveries.

Nitralloy steel, with a core hardness up to 350 Brinell if desired and a case hardness of 950 to 1100 Brinell, offers the mechanical engineer opportunities never before at his command.

Many railroads have used nitrided parts on locomotives, such as valve-motion parts, guides, piston rods, and main as well as intermediate crankpins, and outstanding results have been achieved. Many more parts remain to be tried, including driving axles, which undoubtedly could be designed to permit shrinking a nitrided-steel band on the journal. The high surface hardness of this band should aid in lubrication and retard friction. The heat-resisting qualities of Nitralloy steel should be an important factor in reducing, if not eliminating, heat checks. Both these possibilities can be developed without interfering with the present physical requirements of the various specifications. Nitrided steels present opportunities of reducing the present-day cost of maintenance.

AUTHOR'S CLOSURE

With respect to Mr. Miller's comments on firebox steel, the author agrees that the ordinary steels for certain grades of coal and rates of firing do not stand up and that cracks do develop on the water side at staybolts for a distance of approximately 18 in. above the mud ring.

On the other hand, it is believed that the present design of water leg assists in aggravating the conditions, due to the cross-section being too narrow, and that the design must go hand in hand with better grades of steel to minimize failures. The use of high-grade steels alone will not cure all failures, although it may reduce them.

[3] Materials Engineer, Engineering Materials Department, Camden Forge Company, Camden, N. J.

Coolness of firebox sheets is somewhat of a variable, since the volume of water coming in contact throughout the firebox area varies in density, and it therefore cannot be expected that the heat transfer to the water from a uniform thickness of firebox sheet can maintain the same temperatures, resulting in spotty expansion.

This expansion is controlled by staybolts, all of the same diameter, but with varying lengths in the water leg, resulting in varying resistance offered by each staybolt at its attachment to the firebox sheet, thus causing unequal stresses, as the deflection of a staybolt 12 in. long is greater for a given load than one 9 in.

All firebox sheets should expand uniformly, and staybolts should permit of this, irrespective of the grade of steel used in firebox sheets. This is a contributing factor along with the kind of material selected.

Mr. Higgins' review of the application of nitrided steels is an indication of sound engineering principles brought about by intensive metallurgical developments.

Maintenance is a very large factor in operating expenses, and therefore materials and workmanship are the only known means to bring about a reduction.

Increased wearing qualities cannot be obtained from the present grades of bearing metals and steels coming in contact with them, irrespective of the various systems of lubrication now in vogue, without paying some attention to hardened surfaces, either sliding or rotative.

RR-53-2

Metallurgy in the Railroad Field

By A. E. WHITE,[1] ANN ARBOR, MICH.

The alleged conservatism of the railroads toward changes in the materials going into equipment is explained by their strict adherence to a safety-first policy. The subject matter of the paper is discussed under three main headings of manufacturing methods, materials, and specifications. It is pointed out that, in order to improve a given part, changes in design should be considered which would minimize the chances for defects due to improper or improperly controlled manufacturing practices. Next, a plea is made for better steel-mill practice, closer control, and better inspection. After all these points have been considered, further increases in strength and ductility can be obtained through the use of alloying elements. Attention is given to the steps taken in improving some parts which have previously been a source of serious concern to the railroads.

THIS paper on metallurgy in the railroad field is quite definitely a record of the reactions of an outsider, for the author has done most of his metallurgical work in connection with central stations, the automobile industry, and on the metallurgical aspects of materials for ordnance. It was perhaps the intention in requesting such a paper to secure the unprejudiced point of view of one who holds no special brief for either the steel manufacturers or the railroads.

The railway systems of the United States represent one of the largest industries in the country. They are among the largest consumers of metal products. They have, in consequence, been one of the most important factors in the development of the great iron and steel industries and have contributed to the growth of the non-ferrous industries as well. In this paper discussion will be confined entirely to materials of a ferrous character, such as cast iron and steel.

Railroad companies have been criticized for their apparent backwardness in the adoption of materials which have been developed or have come into common use, particularly in the automotive field, during the past 20 years. They also have been criticized for not taking advantage of the possibilities of increasing strength and other physical properties by heat treatment, in order materially to reduce weights and sections. These criticisms have not taken into account the fact that the by-word of railroad transportation is "safety." In view of what would be the results of any other policy, such a conservative attitude is most certainly to be commended. When one considers that he is practically as safe on a railroad train, even though that train may be speeding through the night at the rate of 60 miles per hour or more, as at home, it is easy to appreciate what the railroads have done in assuring their passengers the maximum degree of safety. How correct this statement is may be appreciated by the fact that only about four or five reportable train accidents occur on Class 1 railroads in the United States per million locomotive miles and that all of these do not result in injury or death. The railroad systems of the United States have evidently done wisely to adopt this policy of safety first, and it is easy to understand the underlying causes for their conservatism toward changes in materials or in their treatment.

The discussion of the subject matter of this paper has been divided into three major sections: manufacturing practice, materials, and specifications.

Manufacturing Practice

Under manufacturing practice will be discussed foundry, steel mill, forge shop, heat-treatment department, and machine shop. A résumé of the problems encountered in each department is presented.

Foundry. The foundry is the source of all cast materials and cast products. The quality of the materials produced in the foundry has been somewhat improved in the last few years by the use of alloying elements. A larger portion of this improvement, however, must be ascribed to more careful methods of handling, closer control, and to more rigid standards of inspection. In some cases the source of the increased quality must be traced back to the design. Properly designed sections are much less likely to carry blowholes, inclusions, or other unsound characteristics than improperly designed ones. When the designer does not take into due account the difficulties that may arise in casting, it is obvious that the composition and quality of the metal have little bearing on the actual strength of the finished piece.

Gray Iron: Railroads use both gray iron and malleable iron. Most of the gray iron carries no alloy additions, though without doubt the advisability of such alloys is now receiving considerable attention. One of the most desirable of the possible alloy additions is nickel, for when present it gives a stronger iron without increasing the difficulty of machining. One must appreciate that it produces these properties only when the cast iron is sound, for it does not, like Aladdin's lamp, possess qualities of making unsound material good.

Malleable Iron: The quality of malleable iron has been vastly improved in the past 15 years. This has been largely due to the efforts of the Malleable Iron Research Institute, which has been instrumental in raising the ductility of the iron from values of a few per cent when expressed in per cent elongation to values of 15 per cent or better. This improvement also has been coupled with increased strength without in any way affecting machinability characteristics. Probably no better example of what may be done through cooperative endeavor in the metallurgical field can be found than that which has been accomplished by the Malleable Iron Research Institute and by those with whom it has cooperated.

Steel Castings: The standards of quality of steel castings for railroad work have been notably raised during the past few years. One of the most important cast parts of a locomotive

---

[1] Director of the Department of Engineering Research and Professor of Metallurgical Engineering, University of Michigan. Mem. A.S.M.E. Received his B.A. from Brown University in 1907 and his Sc.D. in 1925. After graduation he served a few years with the Jones & Laughlin Steel Company, Pittsburgh, Pa. He has been at Michigan since 1911, except for two years spent with the Ordnance Department during the World War.

Contributed by the Railroad Division and presented at the Semi-Annual Meeting, Birmingham, Ala., April 20 to 23, 1931, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

is its side frame. This is a large and a difficult casting to make. One of the large railroad companies reports that in 1923 castings of this type showed properties as follows:

Tensile strength, lb. per sq. in.	73,000
Yield point, lb. per sq. in.	40,000
Yield point as expressed as per cent of tensile strength	55.0
Elongation, per cent	29.0
Reduction of area, per cent	47.0

This company then raised these requirements as follows:

Minimum tensile strength, lb. per sq. in.	78,000
Minimum yield point, lb. per sq. in.	43,000
Minimum yield point expressed as per cent of tensile strength	58.0
Minimum elongation, per cent	22.0
Minimum reduction of area, per cent	43.0

Considerable objections were advanced by the manufacturers of steel castings to this new specification, but the company remained firm, and through cooperation with one or more foundries obtained material that met the specification by more careful practice.

In 1925 this company raised its standards still further, calling for properties as follows:

Minimum tensile strength, lb. per sq. in.	83,000
Minimum yield point, lb. per sq. in.	45,000
Minimum yield point expressed as per cent tensile strength	54.0
Minimum elongation, per cent	25.0
Minimum reduction of area, per cent	45.0

This requirement was successfully met by more careful foundry practice and by the use of alloying elements. To show concretely how these increased standards have been met, the comparative results of tests on two alloy steel frames are submitted; one of vanadium steel and the other of nickel steel.

COMPARATIVE RESULTS OF TWO ALLOY STEEL FRAMES

	Medium-carbon vanadium steel	Low-carbon nickel steel
Average tensile strength, lb. per sq. in.	87,590	79,472
Average yield point, lb. per sq. in.	49,442	48,495
Average yield point expressed as per cent tensile strength	56.5	61.0
Average elongation, per cent	28.5	30.4
Average reduction of area, per cent	53.6	55.8

Vanadium	0.19	..

The values in the four preceding tables are given to demonstrate that an improvement in the quality of the castings was produced, first through better foundry control, and then through the addition of alloys. It should be emphasized that nothing is to be gained through the addition of alloys with poor manufacturing practice, but that when the manufacturing practice is satisfactory, considerable benefit may be secured through the addition of alloys.

Another important casting is the truck frame. Failures of this part have been the cause of derailments. The arch bar truck has now been outlawed by the American Railway Association. This action, together with the adoption of new A.R.A. specifications which require 50 per cent more strength than former A.R.A. specifications, should go far toward eliminating failures of this part. These frames are, however, so far as the author is aware, for the most part of plain carbon steel. Possibly the addition of alloys might still further increase the strength of this casting.

Steel Mill. Much depends upon the steel mills for the production of quality material. Steel mills, however, should by no means be held entirely responsible for all metal failures, since design, forging, heat treating, and machine-shop practice are also important factors in the production of fabricated materials. Yet if steel is finished with pipes, seams, laps, inclusions, or has not been properly heated before it is subjected to the various rolling operations, it is apt to fail because of these conditions. In fact, subsequent forging, heat-treatment, or machining operations cannot eliminate these difficulties. Nor should one unduly criticize steel mills for furnishing materials of this type in the absence of adequate specifications or when the prices have been forced down through competitive bidding to a point which discourages rather than encourages careful control and minute regard for all details which lead to the production of metal of the highest quality. One detail of steel-mill practice of great importance in the production of sound steel is the assurance of proper discard of the ingot. This discard should in all cases involve both a top and a bottom discard. The top discard should be of sufficient amount to render the metal free from piping and undue segregation. In the case of top-poured ingots, the discard should probably be 25 per cent or more. In some cases it should amount to as much as 40 or 50 per cent. It should be noted that no metal has yet been produced which does not have a certain amount of segregation. Careful inspection of steel really requires a deep-etch test in order to ascertain if the metal is reasonably free from segregation.

Ingots when cast should be cooled slowly in order to free them, to as great an extent as possible, from internal strain. Conditions of cooling are not the same for all metals. Plain carbon steel can be cooled at a more rapid rate than certain alloy steels. In fact, some of the tender alloy steels should be most slowly cooled. Ingots, when placed in soaking pits preparatory to blooming, should remain in the pit long enough to permit a uniform temperature to be secured between the center and the outside of the ingot. Under no conditions should an ingot be rolled when the metal in the center is in a liquid state, since this would result in a bled ingot. The heating of billets previous to rolling should be carefully and intelligently performed. The metal should not be brought up to heat too rapidly, nor should it be brought to too high a heat.

The rolling operation also should receive careful consideration, as it is unwise to reduce sections too drastically—that is, by too few passes through the rolls.

All of these comments relate to both plain carbon and to alloy steels. Alloy steels, however, as a class, are more tender than plain carbon steels and require, in consequence, more careful handling and treatment. In procuring alloy steels, therefore, considerable weight should be given to the experience and reputation of the manufacturer.

Forge Shop. What has been said with respect to the heating and the rolling operations in the steel mill applies with equal force to the forging operations. Care must be taken to see that the metal is not brought up to the forging heat at an undue rate and that it is not heated above the proper forging temperature.

Further, in the forging operation, care must be taken not to work the metal much below its upper critical temperature. Again, alloy steels, since they are more delicate than plain carbon steels, should be handled with greater care.

Heat-Treatment Department. Various types of heat treatment have been recommended for some of the various classes of railroad steels. These suggested treatments have, in the main, consisted of a water quench, followed by either a low- or high-temperature draw; an oil quench, followed by either a low- or

high-temperature draw; a normalizing treatment, followed by a low- or high-temperature draw; or an annealing treatment. In the main, the most desirable heat treatment is to normalize and to subject the piece to a high-temperature draw. Normalizing consists of heating above the critical temperature and allowing the metal to cool in the air; drawing consists of reheating the material to some point below the critical temperature to remove internal strains. Such an operation does not, of course, bring out the maximum strength possible in the metal, though it does bring out maximum toughness. It is also less likely to produce checks and cracks in the metal and fits it to withstand shocks more successfully. This treatment is probably the best all-round one that can be recommended for railroad material of both the plain carbon and alloy steel grades. There is also a tendency in practice to lower the carbon somewhat so as to still further improve the toughness and ductility of the metal.

Machine Shop. Operations in the machine shop must be performed with care and precision. The author's attention has been directed to a number of failures which have occurred because of tool marks which apparently acted as the foci of failure. It seems hardly possible that these conditions could exist if, when the machining operations had been finished, the materials were subjected to adequate inspection.

Materials

The ferrous materials used for railroad equipment may be classified according to the use to which they are put. It is possible to place them in five general classes: structural steels for bridges and buildings, structural steel for cars and coaches, reinforcing steel for concrete, locomotive steel, and rail steel. It would of course be quite impossible to discuss the materials used for all of the various equipment parts which are purchased. This discussion has been limited to a consideration of a few of the important parts in rolling stock and rails.

Rolling Stock. The material of which a few of the principal parts of rolling stock are made are discussed at this time.

Side Frames: Locomotive side frames, which have been previously mentioned, are usually made of cast steel, either alloy or plain carbon. When alloys are used, they are generally of the carbon-vanadium or carbon-nickel type. The addition of these alloys makes it possible to retain strength, to maintain and, in fact, build up, ductility, and at the time same to permit the lowering of the carbon content. In recent years much attention has been given to these parts, and a very decided improvement has been made in their quality. Carbon-vanadium and plain carbon steels are also used in forged driving rods, crankpins, and similar parts.

Wheels: Car wheels originally were made of cast iron. This practice led to many failures accompanied by derailment as the size and weight of the equipment increased. For the most part, cast-iron wheels are not used on equipment when the weight is over 70 tons. Rolled steel wheels are generally used on all freight cars of over 70 tons, on all passenger cars, and on all locomotives and tenders, except for the driving wheels and the large-sized trailing wheels. Because of the gradual displacement of cast-iron wheels by steel wheels there has been a material decrease in derailments. The railroad engineers are therefore recognizing that, in general, failures due to wheels are no longer a source of serious importance.

Springs: Although many springs are still made of plain high-carbon steel, there is a trend toward the adoption of alloy steel. Many springs are now made of either silico-manganese or chrome-vanadium steel. No indications have come to the author's attention of any great difficulty experienced with springs, so that this matter has not been given prominence in this discussion.

Boiler Plate: The advisability of using nickel and silico-manganese steels for boiler plate is attracting considerable attention at the present time. This has been due to the fact that the designers of locomotive boilers are going to higher operating pressures and temperatures. These designers desire to maintain the same factor of safety as formerly without increasing weight. They are therefore giving consideration to alloy steels of the type mentioned. Already, the Canadian Pacific Railroad has used boiler plates of nickel steel with very satisfactory results. This steel has a further advantage in that it is not apparently subject to aging or recrystallization at operating temperatures. It must be recognized that though, when properly made, it is an improvement over the plain carbon steel, yet it is not as simple a steel to make as a plain carbon steel and requires considerable care in its manufacture and in the inspection of the finished material.

Tubes: The boiler and superheater tubes in locomotives are, for the most part, of plain carbon steel. The author sees no occasion at this particular writing for considering changes in the composition, particularly for boiler tubes, although it is claimed by some railway systems that tubes of nickel steel undergo less deterioration from corrosion. With the increase in operating temperatures and pressures, it may be desirable to resort to some type of alloy which has a greater stability at high temperatures than plain carbon steel. Several alloys of this type are now in process of development, though, so far as the author is aware, there has been no general test, or at least no general adoption.

Axles: The one part of the moving equipment which is still giving considerable trouble is the axles. A large portion of the axle failures result from overheating at the journals. Efforts are being concentrated upon improvements in the quality of lubricating materials, upon shop practices, and upon closer inspection. Some of these failures are attributed to tool marks; others are said to result from a too rapid cooling of an overheated journal which is responsible for checks or cracks. These in time develop into fractures and failures. Many of these axles are of plain carbon steel; others are of alloy steel, frequently of the carbon-chrome type. Some engineers have suggested raising the carbon content of the axles in order to increase their strength. This, however, is not the remedy for failures resulting from overheating of the journals, since higher carbon will decrease the ductility and hence increase the chances of cracking. There is a tendency, therefore, in the production of axles to reduce the carbon and build up the desired strength by means of alloys. Likewise, the heat treatment given to these axles is usually of the normalizing type, followed by a high draw. These changes—the lowering of the carbon content and the alloy additions which do not harden, but toughen, the steel—combined with the type of heat treatment mentioned, produce a steel which is as little affected by service conditions as lies within the power of the metallurgist to produce.

Rails. Rails are, in the main, of three types: plain carbon steel, a semi-alloy steel, and a straight alloy steel. By far the largest tonnage of rails are of plain high carbon. A semi-alloy steel containing from 1.25 to 1.75 per cent of manganese is finding considerable favor in practice. Other alloy steels have been tried out experimentally, although too recently to permit any conclusions regarding their comparative value. A straight alloy steel frequently used by the railroads for frogs and crossings is the manganese steel carrying from 11 to 14 per cent of manganese.

Because of disasters which have occurred due to rail failures, the quality of rails has been continuously and consistently investigated for many years. The one thing most feared in rails is transverse fissures. These fissures vary in size from

sections of small area to sections up to 4 square inches. They are of infinitesimal thickness. As the name implies, they are at right-angles to the length of the rail. Many theories have been advanced explaining the cause, but as yet no one of these theories has gained general acceptance. The railroads have spent hundreds of thousands of dollars endeavoring to develop an inspection method that would detect fissures before rail failures occur. They met with little, if any, success until the problem was given to the late Mr. Elmer A. Sperry, who worked out an electrical resistance method for the detection of these flaws. This method is now being used by a number of systems and represents a very great advance over all previous methods. It was almost, if not quite, the last great piece of research which Mr. Sperry brought to a successful culmination.

Special Purposes. There are a number of places in which alloy steels are used for definite and specific purposes. For instance, the bearings of the generator developing electricity for the locomotive headlights, etc., are alloy steels, some of which are of the carbon-chrome type and others of the carbon-chrome-molybdenum type. The roller bearings on locomotives, tenders, and freight and passenger cars when used are mainly of alloy steel.

Of course, in railroad equipment some parts, particularly freight cars operating in an industrial section, are subject to corrosion. The plate for these cars frequently carries a small percentage of copper, as this type of material is somewhat more resistant to corrosive conditions than plain carbon steel. Stainless steel is too expensive a type for this use, although it is finding some favor today in the fittings of passenger and Pullman cars, particularly the latter.

Distribution of Material. Although in this paper the subject of alloy steels has been extensively discussed, plain carbon steels and ordinary cast and wrought irons still represent the bulk of the material that goes into a locomotive. This fact is well brought out in the table herewith, which gives a material distribution on the basis of weight of one type of modern passenger locomotive.

DISTRIBUTION OF MATERIALS IN A LOCOMOTIVE

(Light weight of engine and tender is approximately 455,200 lb., of which 19,355 lb. represents important specialties such as air pumps, booster, feedwater heater, and stoker. This leaves a balance of 435,945 lb. for consideration.)

	Weight, lb.	Per cent light weight, engine and tender (435,945 lb.)
Alloy steels. Normalized carbon vanadium. Main rods, side rods, trailing-truck equalizers, front and rear main engine transverse equalizers. The equalizers form a part of the spring rigging	4,800	1
Iron, wrought. The principal items consist of wrought iron used for staybolts, engine bolts, piping, drawbars between engine and tender, drawbar pins, safety chains, and engine truck equalizers, the latter being a part of the truck spring rigging	26,300	6
Iron, cast, malleable, and gun. About the only item of importance in cast iron consists of the superheater header. Gun iron is used for cylinder and valve chamber bushings, which, although of considerable importance, represent only a small percentage of the total weight of the locomotive. The use of malleable iron is confined to certain miscellaneous details	4,300	1
Miscellaneous. Bronze, copper, wood, glass, brick, asbestos, etc.	9,500	2
Plain carbon steel, wrought and cast irons. This group covers the bulk of the locomotive and represents such items as boiler and tank steel, main engine frames and cylinders, tender frames, engine and tender trucks, brake and spring rigging parts, valve motion, wheels, axles, pilot, etc.	391,100	90
Totals	436,000	100

Specifications

All of the major railroad companies either have their own specifications or else use those of the American Railway Association or those of the American Society for Testing Materials. In fact, the specifications used by the railroads draw very largely, if not entirely, upon these two latter sources. These specifications have done much toward building up and improving the quality of materials used by our railroads. It is interesting to note that in some micrographic tests are required in order to assure the purchaser of suitable grain refinement.

The specification of one of the large systems for cast-steel truck side frames is likewise most interesting. This specification is unusually thorough and complete and has doubtless gone far toward the great improvement in quality which has taken place in the last few years in this particular part.

Acknowledgments

The author wishes to express his appreciation to Miss M. A. Brook and to Mr. R. Schneidewind for their assistance in collecting the material, and to Mr. Schneidewind for his aid in the preparation of this paper; also to Mr. W. H. Sellew for his kind suggestions and review.

TEX-53-1

Control of Picker-Room Humidity

By NORMAN E. ELSAS,[1] ATLANTA, GA.

This article attempts to deal with the subject in a non-technical manner. The control of the amount of moisture in cotton laps delivered to the card room is highly desirable. Cotton manufacturers desire uniform weights for any given unit of length from the ounces per yard of picker laps to the grains per hank in the final yarn. If laps delivered to the card room contain widely varying percentages of moisture, though a lap scale may indicate identical gross weights, a variation in weight per yard is immediately begun at the cards which must be corrected by gear changes in subsequent operations. By holding picker laps to very close limits as to the net weight of cotton contained for the same number of yards of lap produced, the beginning of evenness or the elimination of variation in subsequent operations is attained.

THE matter of humidity control and "regain" in cotton has been given much more thought and study during the past few years than in the many centuries since the beginning of the cotton-textile industry. At any rate, the thought has been of a constructive nature, rather than merely attempting to get along with the least amount of equipment necessary to aid nature.

The term "regain" as it will be used hereafter has reference to the percentage of moisture in cotton on a basis of weight to a bone-dry condition. While it is possible to work out a quite definite relation between relative humidity and per cent "regain," from a practical standpoint the variation in the nature of the raw stock itself will have as much or more bearing on the final "regain" in stock leaving a picker room as does the variation from a true parallel between relative humidity and this "regain."

The United States Department of Agriculture has set forth the fact that it considers the cotton fiber in its normal condition when it contains $8^1/_2$ per cent by weight of moisture from the bone-dry condition. Cotton manufacturers have found that the friction in drawing one fiber over another causes sufficient heat to decrease the moisture content to such an extent that humidifying apparatus is necessary to prevent this "evaporation." Cotton must have a certain amount of moisture present in the fiber in order to prevent brittleness.

Throughout the Southern States the meteorological bureaus have indicated a variation of relative humidity that would indicate a "regain" as low as $1^1/_2$ per cent to as high as 13 per cent.

With this variation before us, it is evident that there can be a variation in the weight of any given amount of cotton by as much as 10 per cent on account of the moisture content alone. These extremes of atmospheric condition will often take place within a space of 48 hours.

It seems rather peculiar how few manufacturers have paid a great deal of attention to this feature, in view of the usual care taken to see that picker laps weigh exactly alike. (A finisher picker is set up to operate for an exact number of yards, and then the flow cotton is cut off; assuming the same weight per yard, all laps should weigh the same.) In the event that there is a widely different amount of moisture contained in the cotton itself, does it not seem rather futile that the mill men have attempted to hold lap weights within a variation of less than a quarter of a pound from a standard?

With the thought in mind that this particular condition could be greatly improved upon, study was given to some manner of controlling the atmospheric conditions in the picker room.

One of the first ideas that occurred was to determine upon some means of recirculating the air that was exhausted to the dust pit, after relieving this same air of the dirt and lint. This appeared to be rather simple at first, but the opinions of the many different companies that were approached with the definite proposition for accomplishing this were all rather dubious and indicated an expense far beyond any practical amount.

The next idea was to so condition the air introduced into a picker room that it would be unnecessary to recirculate the air discharged through the picker fans. This second thought was taken up also with various other equipment manufacturers, and this cost was also found to be quite excessive.

For the information of those not familiar with the amount of air normally handled by an individual picker it should be stated that each picker fan handles a minimum of 1200 to 1800 cu. ft. of air per minute. The normal picker room for many years has contained three picking operations, Southern mill operations requiring approximately 12 finisher pickers to take care of 50,000 spindles. In addition to the finisher pickers there were as a rule 12 intermediate pickers and approximately 8 or 10 breaker pickers. The total number of fans operating, therefore, exhausting air from the picker room, would be approximately 32 to 34, moving over 40,000 cu. ft. of air per minute.

Several attempts were made to control the weight of laps indicated by the lap scale, to make due allowance for the relative humidity changes in the atmosphere. Several scales were drawn up, so that an indicating hand could be set on the lap scale to allow for "regain" as indicated from a relative-humidity scale. There also was brought out an accurate type of indicator that will read "regain" directly for the indicator on the lap scale. Devices of this kind must necessarily depend on human supervision.

The importance of accurate moisture-content regulation in laps going to the card room warrants close control. Certainly these devices are better than none at all, and quite satisfactory results can be obtained where consistently followed up by the management.

Before leaving the matter of devices that will aid in the maintenance of even numbers through the spinning, it is well to mention "evener drawing." One of the best mills in this country does not attempt to weigh laps except once a day in order to check on the different machines to see that they are in reasonable adjustment. They then make no attempt to hold the sliver from the cards to a definite number of grains per yard. They do use two processes of drawing, however, the first drawing being

---

[1] Secretary, Fulton Bag and Cotton Mills. Jun. A.S.M.E. The author was born in August, 1896, in Atlanta, Ga., and attended local public schools and later military schools locally and in Massachusetts. He was graduated from Phillips Academy, Andover, Mass., in 1914, and Cornell University with M.E. (E.E. certificate) in 1918. He was in the Naval Aviation Corps during the war, and entered the employ of Fulton Bag and Cotton Mills in 1919, being elected director and secretary on Jan. 9, 1922.

Contributed by the Textile Division and presented at the Semi-Annual Meeting, Birmingham, Ala., April 20 to 23, 1931, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

of the ordinary type, but the second drawing being "evener drawing." Of course by the time the cotton fiber has reached this second process of drawing, the amount of moisture contained is quite uniform and in accordance with the controls operating throughout the card room. Therefore the "evener drawing" can be made to operate quite satisfactorily to eliminate any unevenness in the weight per yard of the various slivers being fed to it.

Evener drawing is quite expensive, however, and certainly too expensive for a mill already in operation to install at the expense of throwing out otherwise satisfactory drawing frames. In addition, "evener drawing" requires considerably more attention on the part of the section men and fixers and a higher cost of upkeep in operation.

The first really practical method of controlling the amount of moisture in picker laps resulted from the development in recirculating the air necessary for picker operation, within the picker itself.

The idea which started the investigation of recirculating the air in a picker began with accomplishing this in a soft-waste machine. In one mill it became necessary to move a soft-waste machine to a new location, and the suggestion was made to put it on one of the upper floors of the mill where it could be in proximity to the point producing the soft waste. It then seemed difficult to connect this machine in its proposed location with the dust pit. Since all the stock to be fed through the machine is free from dust and trash, it seemed possible to recirculate the air within the machine. It was then done by mounting the machine on skids and flooring with sheet metal. In addition, since soft-waste machines are a continual source of fire, which spreads throughout the dust pit, this trouble was eliminated.

This was the basic idea on which further developments were carried out.

For the past 10 years tremendously rapid strides have been made in the opening processes, in an effort to eliminate as much of the undesirable fiber and foreign matter as is possible before the stock is fed to picking equipment for making into a lap. Most remarkable results have been obtained in this field, it being possible now to deliver stock that is practically free from all dust, which would often form a veritable cloud in many card rooms.

With the ability to eliminate dust and the heavier types of dirt in the opening processes, it became evident that the air being discharged by the fans in the final picking operations was relatively clean. In fact it is quite feasible for one to breathe comfortably, the air being discharged from a picker where the opening processes are efficient.

It was necessary to experiment to a great extent to develop the proper type of baffles and air passages to insure performance in a picker set-up to recirculate its own air, equal to that obtained from a picker discharging normally into the dust pit. This has been finally accomplished, and continual watching and testing have shown the laps produced on recirculating pickers to be indistinguishable from those produced on the pickers operating in the usual way in the same normal atmosphere.

After equipping a complete picker room with the recirculating device, it was then only necessary to install sufficient humidity and proper automatic control to maintain an approximately constant "regain" in the cotton. Satisfactory results were noted immediately, and they have been continually obtained over a period of more than two years. The necessity for continually changing the draft gearing on drawing and subsequent operations was immediately cut to about 10 per cent in number and magnitude.

Most cotton mills that are carefully run have followed the practice of sizing drawing at least three times a day, and frequently as many as five or six times a day, and making adjustment in the drafting to compensate for the varying weights in the drawing produced. Naturally this showed quite a wide variation, as the laps from the picker room contained varying amounts of moisture according to atmospheric conditions. With control of humidity in the picker room, it is now unnecessary to change the gearing more than two or three times a week, and in each case the changes are of a very slight nature.

The necessity for continual changes of gearing brought about some additional variation in the sliver from that which would normally be brought about on account of varying "regain" in the stock itself. Cutting out the necessity for these changes has eliminated further variations in the weight of the sliver and subsequent rovings.

Naturally the advantages obtained in evenness throughout the card room are transmitted on through the spinning to the weaving. It would be most interesting if a change of this kind in controlling picker-room humidity could be made in a mill and the subsequent benefits checked directly without other mechanical improvements being made during the same space of time. Unfortunately, the author has no way to allocate the benefits derived solely from humidity control in picker rooms, since new equipment was in process of installation in various departments at the same time the development was being accomplished in the picker room.

There is no question of the value of the improvement itself, since the benefits are immediately indicated in the evenness of the lap weights, the evenness of the card sliver, and rovings, during consistent weighing throughout the plant and at widely varying seasons.

Another most important direct saving from the use of recirculating pickers is the elimination of enormous demands for heating steam during cold seasons. The heating of thousands of cubic feet of air per minute in freezing weather is no little expense. This heating also adds a variation factor to the moisture content of the cotton which must be corrected in the gearing changes later. A feature of controlling the humidity in the picking and opening departments that it might be well to mention is the necessity in most mills to transport cotton by means of a condenser from opening equipment or from bins to the final distributing device over the pickers. This cotton has already been thoroughly cleaned in the opening processes, and the atmosphere in the opening room or the bins may be held to a constant relative humidity. Naturally to draw the air from the bin room or the opening room and to discharge it into the dust pit through a condenser located in the picker room itself would constitute a loss in humidity that would have to be replenished by excessive humidifying capacity in the bin or opener room. To prevent this it was found that exhaust from the condenser fan could be returned to the room from which the condenser system is fed, by enclosing the mouth of this discharge pipe in a long burlap bag. This burlap bag acts exactly in the same manner as the ordinary vacuum cleaner bag familiar to every housewife. The efficiency of the burlap for this particular work is practically 100 per cent, and the air escaping is free from lint and dust. Of course, the bags must be cleaned periodically, but once a week is sufficient.

All of this is simple enough where the cotton contains normal or less than normal moisture.

There is one further step in controlling the percentage of moisture in cotton that is rightfully a part of this discussion, but experiments have not been carried sufficiently far to indicate that a definite recommendation toward their adoption would be in order. As originally stated, raw cotton fiber contain varying amounts of moisture but $8^1/_2$ per cent by weight has been accepted as the standard by the United States Government. Unfortunately, the cotton does not know this, and from

actual tests bales may be delivered to a mill with a percentage of moisture varying from as low as 3 per cent to as high as 18 or 20 per cent, without it being readily detected by "feel."

From the fact that the moisture content of the raw cotton can easily vary 15 per cent from bale to bale, it is clear that some recognition should be given this by the cotton manufacturers so as to bring all stock to the same condition of "regain" prior to the picking operation. It is evident that, if cotton contains more than the proper percentage of moisture, this excess cannot be removed merely in the picking operation, where there is a controlled percentage of humidity approaching $7^1/_2$ per cent "regain" for the cotton.

Cotton fiber absorbs moisture most readily, but the rate at which it gives off this moisture is very much lower under normal atmospheric conditions, mainly because the "terminal differences" are not so great.

Many mills provide bins in which cotton is allowed to age after passing through the opening and mixing processes, before being fed to the pickers. Where there is considerable variation in the moisture content of different bales, excellent results can be obtained by having the humidity in the bin room controlled to give a $7^1/_2$ per cent "regain" and by having fans mounted on the bin walls so as to cause a constant circulation of this controlled air over the stock in the bins. The circulation has little effect on cotton at the bottom of a pile in a bin, but it is exposed a sufficient length of time to the controlled atmosphere while the bin is being filled and emptied.

When cotton contains upward of 10 per cent of moisture, there is a strong possibility that some inexpensive method of drying this excess moisture would be of material assistance before the picking operation. Rather crude experiments have been carried on in direct manner to accomplish this where cotton is conveyed over a reasonable distance to a condenser. The method pursued is to pass the air feeding into this conveyer pipe over hot coils that immediately brought the "regain" of air in the pipe down well below 5 per cent, regardless of outside conditions. Naturally, this air being quite warm and in intimate contact with the loosened fibers during the conveying process, a good deal of moisture is removed from the stock. In addition, this hot blast of air must pass through the cotton deposited on the condenser screen before it can be released to the dust pit, so that some additional elimination of excess moisture takes place at this point.

There are probably several simpler methods by which raw cotton, when once opened, can be so treated that its percentage of moisture can be brought down slightly below normal, and when this development is made, with controlled humidity conditions in the opener room, in the storage bins, and in the picker room, certainly great improvement in the regularity of manufacturing cotton into yarn can be expected.

Discussion

R. S. Curley.[2] The control of humidity in cotton prior to and during the picking operation has not been given the attention which its importance warrants. While some attempts have been made to humidify picker rooms where 20 to 30 fans were each drawing out 1500 or more cubic feet of air per minute, the expense entailed and the somewhat negative results obtained have not encouraged any general adoption of this practice. Some experiments have been made to determine the amount of variation in the moisture content of finished laps. Many attempts have been made to vary the standard weight of the finished lap in accordance with variation in relative humidity in the picker room. None of these experiments have given any practical answer, because they did nothing to overcome the evil at its source.

The system described in this paper gives a definite and effective means of control of the humidity from the very beginning. The opening room can be easily humidified to the same degree as the picker room, because the air drawn by the fans in transporting the cotton from one operation to the next is returned to the room of its origin. In this way cotton is subjected while in a finely divided state to enormous quantities of air passing through it during every operation of picking and opening. Cotton in contact with rapidly moving air takes in or gives up moisture very much more rapidly then when simply exposed to still air. A recognition of the value of condensers for removing free dust and for quickly balancing the moisture content in the cotton is apparently one of the foundations on which this system was formulated.

Taking air at 70 deg. fahr. and 65 per cent relative humidity, each cubic foot contains 5.25 grains of moisture. Each fan in a picker moves about 1500 cu. ft. of air per minute. The average production of the modern machine is about 360 lb. per hour, or 6 lb. per minute. That is, 250 cu. ft. of air passes through each pound of cotton going over the screens of the picker. The amount of moisture necessary for $7^1/_2$ per cent regain in cotton is 525 grains per pound. The 250 cu. ft. of air conditioned as described contains 1312.5 grains of moisture, or $2^1/_2$ times the moisture required to bring the cotton from dry to $7^1/_2$ per cent regain. It is seen from the foregoing that a proper condition of the air drawn through the screens has a great influence in maintaining the desired regain in the picker lap.

Another important feature is the control of cleaning. Where cotton is held at $7^1/_2$ per cent regain, its freedom from static during the beating operation permits the elimination of quantities of light particles which under dry conditions would tend to adhere to the fibers. The fibers are not so brittle in themselves and tend to lie straighter under conditions of proper regain, so that there is less possibility of breakage from beating.

Perhaps one of the most important results obtained is the maintenance of nearly constant density during the passage under the evener roll. It is well known that an evener weighs by measuring the thickness of the cotton as it passes between the plates and the roll. It is also known that the evener can only be accurate as long as the density remains constant. It is one of the unfortunate qualities of cotton that its density varies widely with changes in moisture content. A thorough exposure of cotton to large quantities of air with proper moisture content permits delivery of the cotton to the evener at a constant density which gives the evener a chance to function at its highest possible efficiency.

It is in this particular that this system is vastly superior to that of changing the standard weight in accordance with changes in relative humidity of the surrounding air. This latter arrangement leaves the evener operating under conditions of constantly changing density for which it is unable to compensate.

The author states that the humidifying of the bins is only effective during the filling and emptying of the bins. This statement is quite true and should be further emphasized. Cotton in a loose state is an excellent insulator, and air does not ordinarily penetrate far beneath its surface. Because of this fact, cotton does not change its moisture content to any extent while in the middle of a bin. It will change on the surface and on the floor, particularly on a cement floor. It is therefore evident that the benefits of aging cotton in the bins were largely imaginary. The only real benefit came from blending many bales through the stack of loose cotton. Where mixing feeders are arranged to obtain this blending, much better humidity control is possible through the use of extra condensers and fans, which pass the

[2] Saco-Lowell Shops, Newton Upper Falls, Mass.

moist air through the cotton in such large quantities as to insure constant regain.

In view of the advantages gained through this system of humidity control, it is certain that many mills can make definite advance in quality of product by its adoption.

The pioneer work already done must direct attention to this opportunity for sound progress.

C. L. Emerson.[3] The author has described an improvement in cotton-mill operation for which engineers have been searching for some time. Heretofore variations in moisture content of picker laps have introduced irregularities in sliver weight at the very beginning of the process, and subsequent operations were forced to even out the inequalities as best they could.

The system is another and very important contribution to the general progress being made in obtaining uniformity so valuable in manufacturing conditions. It is also interesting to note that this system of picker-room humidification would hardly have been practicable until the improvement in opener-room equipment had reached its present state of efficiency. If the cotton had been fed to the pickers in a condition which 10 years ago would have been considered satisfactory, it is quite probable that the air passages in the recirculating pickers would have been clogged with the dirt and leaf removed by the machine, but which under present conditions is extracted in the opener room before it ever goes to the pickers.

In an effort to supply some humidification to picker laps during particularly dry periods, other mills have previously installed one or two atomizer heads to spray directly on the finished picker. These heads were usually hand controlled and were at best only a makeshift device to provide a certain rough compensation.

The bins for cotton storage between the opening and picking processes which are proposed by the author to permit a considerable amount of the humidification being accomplished in the opener room itself also have certain subsidiary advantages and are frequently used by other mills which do not attempt to humidify their picker rooms. The argument for their use is to permit the aeration of the fibers and also to let them uncurl from their forced compression in the bale. The system here discussed would add another incentive for the use of bins.

The saving in the steam required to heat the picker room in winter is quite an appreciable one. Some mills, in order to save part of this heating expense, allow the picker and opener rooms to remain at a temperature much lower than other parts of the mill. This is not at all conducive to efficiency on the part of the opener-room and picker-room operatives.

H. S. Busby.[4] The thing of outstanding interest about this paper is the method of attack of the problem, which is a purely analytical and engineering one, rather than that of rule-of-thumb procedure so common in textile manufacturing.

[3] Robert & Co., Inc., Atlanta, Ga.

[4] Director, A. French Textile School, Georgia School of Technology, Atlanta, Ga.

The conclusions reached in the paper would seem to indicate the advisability of supplying cotton for shipment wrapped in a moisture-proof container or one as nearly so as possible and practical.

This may bring about a reconsideration of the present method of baling cotton, and suggests a close-mesh cotton-fabric container, if it can be shown that such a wrapper will retain moisture within the package for a considerable period of time.

It also suggests the advisability of the cotton manufacturer purchasing fiber so processed in the field as to secure dependable uniformity in moisture content. An important development has taken place in this field within the past year, and economy in shipping, in manufacturing, and in appraisal value is closely tied to this problem.

It is to be regretted that a more general check is not available of the method of recirculation described in the paper. It seems that if the mills having different types of opening processes were to report results based upon this or similar procedure, most of the information regarding practical ranges of recirculation, cleaning, and net yield could be reported dependably within a reasonably short period of time. There is no doubt that this would cause basic redesign of textile preparation equipment.

It is significant that most of the recent developments in preparation machinery, with the exception of the Lord card, have contributed little, except revision, refinements, and details, for a number of years. The huge tonnage of machinery necessary for the production of a single thread, with its consequent investment burden, suggests a redesign along such lines as indicated by this and similar experiments to be not only of fruitful outlook, but an emergency measure.

Author's Closure

Mr. Curley has brought out a pertinent point not touched upon previously. There is certainly a wide variation in the operation of the evener on a picker due to the moisture content of the stock passing through it. While Mr. Curley does not give any specific figures, nor has the author any available, it has been the experience of a number of mill men that a picker running properly on dry cotton and turning out the proper weight laps will, when switched to stock having a higher moisture content, immediately begin delivering laps that are considerably overweight. This excess of weight is not due solely to the moisture contained in the stock, but, as pointed out by Mr. Curley, is due to the increased density of the stock permitting more actual pounds of cotton to pass through the eveners per revolution.

The author regrets that there were no discussions disagreeing with the proposal of the original paper, since there are undoubtedly a number of able textile manufacturers who do not believe in this proposed method of controlling picker-room humidity, though it is in actual operation at the present. It is only by disagreement and discussion that new features can be brought to light, and the author wishes to take this opportunity to invite correspondence on this matter.

Development in Gaseous Fuels and a New Singeing Application

By R. S. VAN NOTE,[1] BALTIMORE, MD.

Liquefied petroleum gases are finding an application in various process-heating work. In the textile industry butane is available as fuel for singeing, calendering, gas tenter-frame heating, and yarn-singeing operations. New cloth-singeing equipment has recently been developed and is discussed in the paper.

THE customary usage of manufactured gas, gasoline gas, natural gas, and oil as fuels for cloth singeing, calendering, yarn singeing, and tentering operations is too familiar to call for extended discussion here. Their use throughout the industry is general, and knowledge as to their characteristics and methods of application is well known. A brief résumé of the use of these familiar fuels is desirable, however, and recalls that: (1) Manufactured gas, gasoline gas, and natural gas are suitable fuels for open-flame singeing, rotary- and stationary-plate singeing, calender and tenter-frame heating, and yarn-singeing operations; (2) oil is frequently employed in heating rotary- and stationary-plate singers.

The commercial production of the liquefied petroleum gases made available another source of fuel for the operations mentioned. Handled as a gas at the burner, with flame characteristics comparable to those of natural gas, liquefied petroleum gases are, from the application standpoint, capable of performing satisfactorily. The scope of their usefulness centers about the economics involved; in short, it is a question of cost per 1,000,000 B.t.u. of one fuel versus another.

The more important commercial liquefied petroleum gases are propane and butane. These are obtained by "stripping" so-called "wet" natural gas or from by-product still gas as produced in oil-refinery practice. They exist as gases under normal atmospheric pressures and temperatures, but are capable of being stored and transported under pressure in the liquid state.

Propane, in addition to its industrial uses, has found a wide application as a domestic fuel for cooking and water heating in areas removed from manufactured-gas service. Butane, in addition to its industrial application, serves as a source of town gas supply through the medium of the butane-air gas carburetion process, and as an enriching medium for gases of low thermal value.

A partial list of the physical properties of commercial propane and butane (a mixture of normal and iso-butane), as given by one distributor, follows:

	Propane gas	Butane gas
Normal state at 60 deg. fahr., 30 in. mercury		
Specific gravity of liquid	0.51	0.57
Specific gravity of gas	1.52	2.07
Latent heat of vaporization, B.t.u. per gallon	778.2	775.7
B.t.u. per gallon liquid	91.370	101.800
Pounds per gallon at 60 deg. fahr.	4.25	4.78
Cubic feet per gallon	36.51	31.27
B.t.u. per cu. ft. of gas	2500	3260
Vapor pressure of liquid, lb. per sq. in. (gage):		
10 deg. fahr.	32	1
32 deg. fahr.	58	8
60 deg. fahr.	98	24
105 deg. fahr.	192	62
Cubic feet of air required for complete combustion of 1 cu. ft. of gas	23.91	31.1

The utilization of butane or of propane for textile process-heating operations is essentially the same; and for the sake of brevity, discussion will be confined to butane.

Shipped by rail in tank cars of special construction, butane is transferred to storage tanks on the manufacturers' premises. Customarily, storage capacity equivalent to four to six weeks' supply is furnished. From the storage tank butane liquid is conveyed by storage-tank pressure to the point of vaporization, usually a small building or shed adjacent to the main plant buildings. Here it passes through straining, governing, and vaporizing equipment. The vaporizer, or gasifier, is nothing more than a heat exchanger, the heat of vaporization being supplied by hot water or low-pressure steam. In passing through the vaporizer, the butane liquid, with a low latent heat of vaporization, is readily converted to the gaseous state, the amount of vaporization being automatically controlled to correlate the supply to the demand.

At the outlet of the vapor governor, adjacent to the vaporizer, the fuel is completely gasified, containing 3260 B.t.u. per cu. ft. From this point on utilization practice differs somewhat. The gas may be diluted to 525 B.t.u. per cu. ft., the average heating value of city gas; it may be diluted to a completely combustible mixture of 96 B.t.u. per cu. ft.; or it may be carried as a straight 3200-B.t.u. per cu. ft. butane gas, undiluted. The dilution medium is air.

When carried as a 525-B.t.u. gas or as a completely combustible mixture, an automatic proportioning and compressing machine is placed in the line next to the vapor governor. It is supplied with the rich gas undiluted, and discharges, in the one case, a partially diluted 525-B.t.u. gas, and in the other a completely combustible 96-B.t.u. gas. The maximum discharge pressure is 2 lb. per sq. in.

Since complete combustion requires 31 parts of air to 1 of gas, in the former case the remainder of the air is supplied at the point of gas utilization; in the latter, being totally premixed at the machine, no further air is supplied. When totally premixed in this manner and carried through the pipe lines as a mixture approved by the Underwriters' Laboratories, protective devices should be provided to insure against burning back through the line. These protection devices are available.

If conveyed as the straight 3200-B.t.u. gas, leaving the vapor governor at approximately $^1/_2$ lb. pressure, the fuel receives its air supply from air blowers, the air line being tied into the gas line at a point adjacent to the burners.

---

[1] Sales Engineer, C. M. Kemp Manufacturing Co. Mr. Van Note was previously connected with the Public Service Electric and Gas Company, Newark, N. J., in the capacity of industrial-gas representative and assistant to the general industrial-fuel representative. He is a graduate of Rensselaer Polytechnic Institute.

Presented at the meeting of the Textile Division, Providence, R. I., Oct. 6, 1931, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

The basis for recommending which of the three methods outlined should be used depends on the process to which the gas is to be applied and existing plant conditions. If a plant has been using manufactured gas and changes to butane, it is customary to use a 525-B.t.u. butane gas. This is because manufactured city gas has approximately the same thermal value, and existing pipe lines and burner equipment can be utilized without major change. Where the fuel consumption is large or processing requires burner equipment adapted to a complete butane-air mixture, the 96-B.t.u. gas proves advantageous. This method is highly efficient thermally and requires but one pipe line. The use of the undiluted or 3200-B.t.u. gas at the burner requires equipment capable of proportioning a large quantity of air with a relatively small quantity of gas, maintaining these proportions under various rates of flow.

The prevailing cost of other fuels in the particular plant locality as balanced against butane costs, taking into consideration all charges involved in either case, is the predominating factor in determining its use. It goes without saying that in isolated regions the choice of a fuel is narrowed down by the inaccessibility to public-utility manufactured or natural-gas lines. This condition exists in many textile plants, and where fuel consumption is large enough to justify the installation, a butane plant may prove desirable.

FIG. 1 BUTANE TANK CAR AND CUSTOMER'S 13,500-GALLON STORAGE TANK

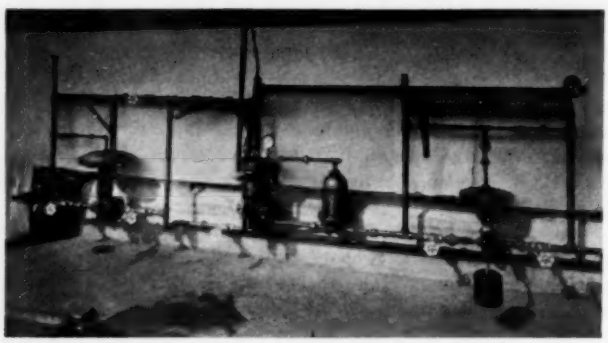

FIG. 2 BUTANE PRESSURE-GOVERNING AND VAPORIZING EQUIPMENT

Butane, as the source of town gas supply, is growing rapidly. The low investment required to build a butane plant makes it economically possible to render gas service in the smaller communities where the higher cost of water or coal-gas plants has hitherto hindered such developments. In certain cases, where obsolete coal or water-gas plants have been in operation, they have been replaced by butane plants.

The single-industry town exemplified by the typical mill village where an industrial load exists can serve both industrial and domestic purposes, the one aiding the other in making the gas-plant installation economically justified.

FIG. 3 FLAME-COMPRESSION BURNER UNIT

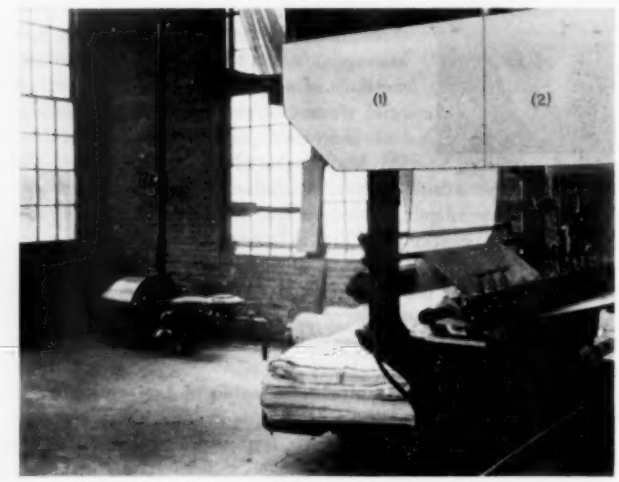

FIG. 4 AUTOMATIC GAS-AIR PROPORTIONING MACHINE AND SINGEING MACHINE, FEED END

In a cotton-finishing plant, the point of heaviest gaseous-fuel consumption is ordinarily in the singe room. Butane is finding applications for this process in open-flame singeing and flame compression singeing.

CLOTH SINGEING

Cloth-singeing operations, in general, have been divided into three classes: (1) plate singeing, (2) open-flame gas singeing, and (3) flame-compression singeing. The first is divided into stationary- and rotary-plate singeing. Plate singeing and open-flame singeing have been in general use for many years. Flame-compression singeing is a relatively new development.

1 Plate singeing depends on cloth contact with heated metal surfaces for its effectiveness. The condition and temperature of the plate surfaces are primary factors in determining the quality of singe secured.

Stationary-plate singeing employs one to seven semi-circular plates, usually of copper, underfired from either side with oil or gas. Thermal efficiency is relatively low due to high radiation losses from the plates and furnace structure. Maintenance

charges are relatively higher than other methods because of the necessity of replacing burned-out plates or of reshaping plates.

Rotary singers are divided into two classes: (*a*) externally fired and (*b*) internally fired. Singeing is effected by cloth contact with a heated alloy rotary plate or roll. In the one case, heat is applied to the external roll surface; in the other, combustion takes place inside the roll itself.

2 Open-flame singeing is done by passing the fabric over a series of gas burners. Singeing is secured by the contact of the flames with the cloth fibers. Gaseous fuel is supplied to the burners in one of the following ways:

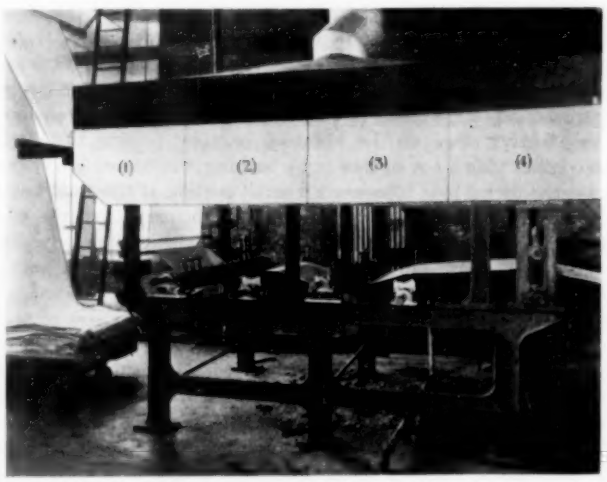

FIG. 5 FOUR FLAME-COMPRESSION SINGEING UNITS, FOR TWO-SIDE SINGEING

a Premixed with air at a central point, a mixture of gas and air under a pressure of $1^1/_2$ lb.

b As straight gas under a pressure of 3 to 10 lb., inspirating air for combustion from the room atmosphere.

c As straight gas, receiving its air supply from a low-pressure air blower, and proportioning near the burner.

3 Flame-compression singeing, developed during the last two years, embodies the principle of liberating a combustible air-gas mixture in a confined space, with the result that combustion takes place in a chamber having a positive pressure. From this it is seen that the flame is not permitted to expand to its normal size, thus the name "flame compression."

In practice, the drilled burner surface forms the bottom of the combustion chamber, water-cooled cast iron the side walls, and the cloth to be singed, the roof. Gaseous fuel, in order to burn in the confined space beneath the fabric, must be fed to the burners as an accurately proportioned and completely combustible air-gas mixture, under an appreciable mixture pressure. This is accomplished by utilizing an automatic proportioning machine, the function of which is accurately to proportion air and gas in the desired ratio, compress and mix to the proper operating pressure, and maintain this pressure and mixture under varying conditions of demand.

Flame-compression singeing is being carried on with city gas, natural gas, gasoline gas, and butane gas as fuels. All of these gases, when proportioned and premixed as heretofore described, are suitable for this work.

To understand the totally different singeing effect secured by flame compression, one must remember that with open-flame singeing good practice calls for a rich gas flame (one containing a deficiency of oxygen for complete combustion), which follows along with the cloth, singeing as combustion completes itself. The operation is carried on in the room atmosphere in the presence of cooling air currents. In addition, when high speeds are run, a current or film of air travels with the cloth. The virtually pressureless soft open flame is unable to penetrate this, and consequently a large amount of the potential singeing effect is lost.

With flame compression the trapped flame exerts a positive pressure on the surface of the cloth, and little heat is dissipated to the surrounding atmosphere. Four flame-compression singers for each singe frame are sufficient to assure high production and a close singe, two units being used for each side of the goods. Each unit consists of a cast-iron, water-cooled combination burner and combustion chamber on which are provided machined cloth-contacting surfaces. Water- and gas-supply valves working in unison enable the operator to control water and gas flow as desired. Flame cut-offs available in every width permit the turning off of any sections of the flame when narrow cloth is being run, and in some installations, permit the operation of two narrow widths of cloth simultaneously over one singer. If independent supply controls are provided for each half of the burner, these widths need not be of the same weight and quality; thus two different singeing effects can be secured on two widths of goods from one singe frame at one time. In an installation such as this, a combined production speed of 600 yd. per min., while singeing face and back, can be secured.

The installation of flame-compression units can be made on existing singe frames with but minor changes in the frame itself. In an installation of four units, alternately facing up and down, cloth is singed both face and back in a single horizontal passage through the singer. By placing the burners off-center, their contact surfaces take the place of carrier rolls and provide the desired contact angle.

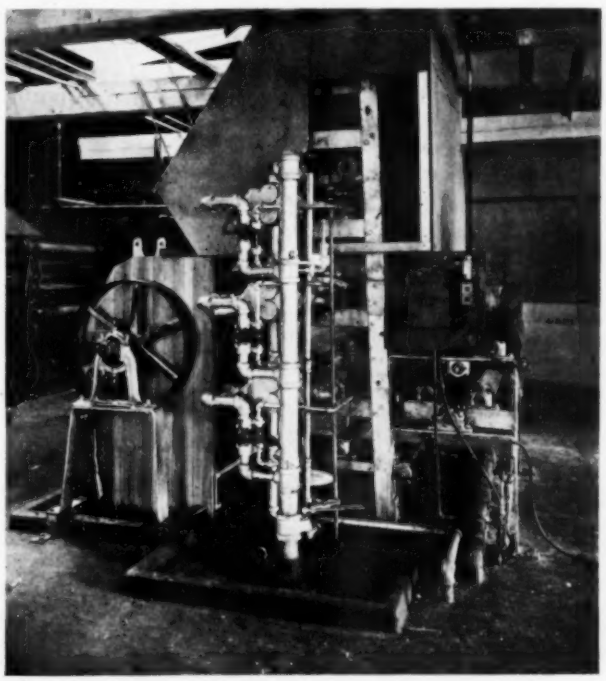

FIG. 6 VERTICAL-SINGEING THREE-FLAME COMPRESSION SINGEING UNITS FOR SINGLE-SIDE SINGEING

An excellent installation of flame-compression units can be secured with the cloth traveling in a vertical plane, the burners being mounted one above the other. This type of singe frame, styled "vertical," occupies less floor space than the conventional horizontal type and facilitates smoke removal.

Discussion

L. E. WAGNER.[2] The author has made some comments on the fuels available for textile operations. The writer is led to make a few observations on the selection of a fuel.

The economy of one fuel over another is probably the most important single factor. It is self-evident that this point must be decided only after a complete study of all the conditions that exist in a given locality. All increments of cost entering into the purchase, delivery, storage, preparation, compression of air or gas, pumping, or cost of auxiliary steam, etc. must be considered. Any tangible savings in labor, production, better quality, and such intangible items which are frequently difficult to isolate must be scrutinized so that the final comparison is made on the basis of fuel burned, balanced against final production.

The physical properties of each fuel must be compared in relation to their effect on the organization and product. Such items as control of combustion, flexibility, cleanliness, etc. all have a definite bearing on the problem, but are sometimes not easy to define.

Present relative values are so disrupted that the problem of selection of fuel is further complicated. For this reason it would seem wise to scrutinize the respective unit costs over a long-time period and to observe past fluctuations in price and to determine if possible the reasons for such fluctuations, so that future trends may be forecast with reasonable accuracy.

In the adoption of a fuel one must be assured of a supply of such fuel, in quantities and at such times as needed. Conditions over which no control is possible frequently affect deliveries. In this respect the public utility is fortunate in that, in case of fuel shortage or other emergency, priority orders are authorized.

Fuel occupying storage space may be at a disadvantage, as space so utilized may earn greater return if put to productive use. Storage of inflammable material always presents a hazard which may affect insurance of the plant as a whole. For instance, liquified petroleum gases are of high gravity, running from 1.5 to 2.0 in the gaseous state as compared to air as 1.0. It is therefore wise to consider the possibility of leaks accumulating as an explosive mixture in basements, etc. Great care should therefore be taken in the design and installation of a handling plant for this material.

Frequently the service rendered by a public utility in assisting its clients in the selection of proper equipment and in following up such equipment has been a deciding factor in the selection of a fuel. A number of large industrial organizations have placed a value of from 11 to 15 cents per 1000 cu. ft. of manufactured gas purchased on such service and on the assurance of a continuous supply of fuel from the gas company.

In the second half of the paper attention is called to a burner which appears to represent a definite improvement in singe burners. The efficiency of this operation always has been low. An effective singe can be obtained only by passing the cloth in contact with a hot surface or by bathing it in flame. In either case the useful heat represents a small portion of the total heat. The rotating plate singer has a greater efficiency than the stationary plate, due to confinement of the heat within insulated walls.

With the new burner, the flame is confined within walls, the cloth to be singed forming the cover. The heat is directed as closely as possible on the work it has to do. Users of this equipment advise that efficiency approaching twice that of open-flame singeing is being secured. Speed of singeing is also greater. In this connection it is only fair to state that greater speed can be secured with gas than with gasoline. The writer would expect this to be true also with manufactured gas over natural gas or liquefied petroleum gases, giving as a reason for this the increased amount of air required for complete combustion of these gases, with the consequent addition of more inert nitrogen to the burning mixture, which slows down the rate of flame propagation and reduces the theoretical flame temperature. Natural gas of 1000 B.t.u. requires nearly twice as much air for complete combustion as does manufactured gas, and butane requires about seven times as much.

This increased amount of inert diluent also may give rise to troublesome carbon deposits within the burner due to the slow-burning mixture coming in contact with the water-cooled burner enclosure. The writer does not think that these deposits would occur in using manufactured gas.

Use of the Butted Seam by Textile Manufacturers[1]

By JOHN M. WASHBURN,[2] HARTFORD, CONN.

Increasing use is being made of the butted seam by textile manufacturers, and this paper defines and illustrates the butted seam, describes many of its inherent properties, and outlines some of the advantages to be gained by its use in the finishing of woolens and worsteds, cottons, silks, and rayons.

IN THE processing of piece goods, it is usually desirable to join one or more "cuts" or pieces in endwise relation. Comparatively recently, the overedge stitch or seam has been adapted to this work, and because of the fact that this stitch permits of end-to-end relations between the pieces of goods, at the seam, it has been termed the "butted seam." Either a one- or two-thread type of overedge stitch may be employed for making these seams, and the appearance of each side of the two types of seams is shown in the accompanying illustrations.

Fig. 1 shows the covering or looper thread side of a seam of the two-thread type. The reverse or needle thread side of this seam is shown in Fig. 2, and the goods are usually seamed so that these threads are showing on the face of the goods. The appearance of the two sides of the one-thread stitch is shown in Figs. 3 and 4. The side shown in Fig. 3 corresponds to that shown in Fig. 1 for the two-thread type of stitch. It will be noticed that the appearance on one side of each stitch, Figs. 2 and 4, is identical.

In making the butted seam the ends of piece goods are usually placed face to face and fed through a machine which trims and feeds the goods simultaneously with the stitching operation. The stitching is applied loosely to the edges of goods so that subsequent processing opens the seam and the goods lie end to end with the overedge threads uniting the pieces, thus producing a flat seam, wherein the cut ends of the goods are confined under the uniting threads.

A processing seam of this type has many inherent properties, among which are:

1 The seam is very little thicker than the goods, particularly when fine threads may be used or when the processing and fabric are such as to make the threads embed themselves in the goods.

2 The uniting threads lie in the direction of the warp threads of the goods, and if shrinkage of the thread occurs, it does not reduce the width of the piece goods at the seam.

3 The formation of the stitch is such that the seam is elastic and may be stretched laterally with the goods without fear of breaking.

4 The seam will thoroughly dry with and in the same drying time as the goods.

5 The practical strength of the seam under longitudinal tension is dependent upon the resistance of the filling threads to pulling from the warp threads of the goods, for a reasonable width of seam. Various widths of seams are available that will hold the great majority of goods through common processes.

6 The one-thread seam may be readily unraveled.

7 The width of the seam is comparatively small, and little goods are wasted.

Inasmuch as the quality of the butted seam is such that it approaches the character of the goods, it may readily be realized that its use for process seaming offers many advantages, but like all developments, its practical advantages and limitations have to be determined by experiment. To gain its full use, it has frequently been found practical to combine processes or slightly revise equipment and method of handling the goods to the end of reducing labor and saving material.

A number of processes in various textile fields, where the butted seam has been found to save labor, material, to speed up the process, or to give a superior result, are hereinafter enumerated and certain advantages given in each case.

Woolens and Worsteds

In the process seaming of woolens and worsteds, the butted seam has been used to advantage for speck dyeing. With the end-to-end relation permitted by the seam, this process may be made continuous, without difficulty in the drying. The seam may be dried in the same time and under the same conditions as the body of the goods, which obviates any shading in color near the seam. For speck dyeing in vat, a number of cuts may be joined, dyed, and subsequently dried as one piece.

In fulling or scouring, joining the ends of the piece goods with a butted seam is not of any particular advantage to the material itself. However, advantage lies in the action of the butted seam on the fulling mill. The elimination of extra bulk avoids the pounding of the rolls as a seam passes through them, thus increasing the life of the rolls and their bearings. If two or more cuts are fulled in the same mill for piece dyeing, this elimination of the pounding of the rolls has a decided advantage in preventing the possibility of wrinkles being pounded into the cloth as the seam of an adjacent cut passes through the rolls.

Use of the flat butted seam through the various extractors permits the liquid to be drawn out at the seam as well as the body of the fabric, which makes it of particular importance in the subsequent drying process. Its use through the crab extractor does not present any particular advantage other than the fact that there are no loose ends to throw liquid as the seam passes through process.

Certain advantages to the material, as the butted seam goes through the drier, have been enumerated. In addition, the seam is elastic and will give filling-wise with the goods, and therefore will not shrink or break as it goes over the tenter frame of the drier. This non-shrinking property helps to keep the selvage

edges of the goods in line, relieving the tenter-frame operator for other work.

The greatest monetary saving of the butted seam is found in seaming for the process of shearing. The great majority of goods seamed with this seam may be processed directly through the shears without raising the revolvers, making it practical to shear the goods to and over the seam, eliminating all waste of material due to incomplete shearing. On certain classes of light-weight, very closely sheared worsted serges, it is necessary to slightly tap the shears when shearing on the back of the goods. In such cases a block of rubber may be inserted between the shear-raising device so that the normal action of raising the shears will only raise them a small fraction of an inch, permitting the shears to go quickly back to place.

Certain manufacturers have found it practical to place four two-blade shears in series, the first shear shearing the back of the goods, a turning cradle being located between the first and second shears, and the remainder of the shears operating on the face of the goods. This entire unit is handled by one shear operator, and the shearing of the goods is completed as the fabric leaves the last shear.

As a rough example of the material saving of a mill shearing 20 cuts per day by the use of the butted seam as compared with a seam which requires raising of the shear blades, it is not unlikely that with this latter seam, at least 9 in. of goods are wasted at each seam due to incomplete shearing. The 20 cuts, requiring 20 seams, would waste 180 in. of goods per day, which, if made at a cost of $2 per yard, would represent a waste of $10 per day. This waste would be eliminated, to which could be added a substantial labor saving.

The elimination, by the use of the butted seam, of the necessity of reducing the weights or raising the cylinder of the press as a seam passes through, permits even pressing throughout the cut, the ends of the piece goods being pressed equally as well as the center.

If the goods are to be decatized, two cuts may be joined and rolled without the use of a leader. A well-butted seam with the proper thread will not "mark off."

COTTON FINISHING

On cotton finishing in general, although there is a distinct saving of material effected by the use of the butted seam itself, this saving does not assume the importance that it does in the processing of more expensive piece goods, such as woolens and worsteds. However, the improvement it brings to the handling of the goods through the various processes saves much material by the reduction of damaged work, and in such cases as the elimination of the pasted seam, a considerable saving in labor is effected.

The fact that the cut ends of material are enclosed within the formation of the stitches is of practical value in singeing operations. This enclosure of the cut ends prevents them from catching fire and "sparking back" on the goods as they are processed over a flame or red-hot rolls.

In bleaching, the butted seam has proved its value due to the fact that the uniting threads lie with the warp threads of the fabric, which prevents reduction in the width of the goods at the seam and at the same time provides an elastic seam, which may be stretched laterally, without fear of breaking during the tentering process. This non-shrinking, elastic seam is of further value in reducing "wrinkle backs" at the selvages of the material as it goes through this latter process. These same properties are of similar value to the processes of mercerizing, dyeing, and drying, where also the butted-seam property of uniform drying is a distinct asset.

The butted seam is processed directly through printing opera-

tions with uniform printing to and over the seam, and the fact that the seam has not shrunk during process and that it is elastic permits printed goods of square or diamond design to be uniform throughout the length of the piece. This seam may be processed without leaving an imprint on the "back gray" material, which might subsequently "mark off" on the printed cloth. The butted seam is also used in the seaming of the "back gray or bump cloth" material itself, making it practical to cut out damaged or heavily inked sections of this material and reseam into a continuous piece.

In the general process of calendering, including such subdivisions as friction, embossing, chase, and shreiner calendering, the inherent properties of the butted seam are of distinct value. For certain calender work, particularly of a drastic nature, it has become usual practice to break the process seams as they come to this operation and replace them with a pasted seam, consuming about 8 in. of cloth, and is of necessity a comparatively slow operation. In some cases, dependent upon the character of the goods, the butted seam is calendered directly as it comes from previous processes, without breaking the seam. In other cases it has been found necessary to reseam for calendering, making a careful butted seam with fine thread. This latter operation is a speedy one and much labor is saved in comparison with the pasted seam.

The butted seam has been found of value to the process of cotton-goods napping, when it is desired to nap both sides of the material. The uniting threads of this seam lie in the direction of the warp threads of the piece goods and do not disturb the wires of the napping brush as the material passes over them, thus increasing their useful life.

When the process of shearing for slubs and loose thread ends is involved on cotton goods, the butted seam is processed directly through such shears without raising the shear blades, thereby shearing all the goods to and over the seam.

This seam is also of particular advantage in the processing of cotton velours, mohairs, and other plush goods, especially for drying operations following dyeing, bleaching, or washing. On these goods the shearing process is rather similar to that employed in worsted shearing, with the addition of the various pile-raising processes between shearing operations, and the advantages of the butted seam for this work are similar to those gained on worsted materials.

Silk Finishing

In the processing of silks for finishing, the butted seam is used to advantage. Such properties of the seam as its flatness and lack of bulk permit proper "steaming out" of the gum from the silk inasmuch as the goods at the seam will respond to this process in a similar manner to the body of the goods. This thorough "steaming out" at the seams materially aids in the subsequent washing and drying processes. This drying process is also benefited by the fact that the seam will dry in the same time and under the same conditions as the goods themselves, making it unnecessary to keep that portion of the goods including the seam at a higher temperature or in the heat a longer time than the rest of the material. Advantages accrue to the printing of silks similar to those that have been described in the printing of cotton. Shearing for slubs and the loose thread ends is, like similar cotton shearing, carried out without the necessity of raising the revolvers as the seam passes through process, thus shearing the material to and over the seam.

Silk velvets and other pile materials are processed to advantage by the use of the butted seam because of its inherent properties, as has been described. Its use for the shearing of such goods makes a worthwhile saving in labor and material.

Rayon Finishing

The uniform drying qualities and the elasticity of the butted seam are of particular value to the processing of rayon materials through the drying and tentering operations. The butted seam is used for the processes of printing and such light calendering as rayon goods receive, gaining substantially the same advantages as have been enumerated under cotton finishing.

Discussion

George E. Bennett.[3] The paper certainly very completely covers the subject and confirms the experience of the writer's company to the extent that there is nothing that can be added to it that will enhance its value. However, one might suggest for the sake of clarity a few slight changes in the description concerning the printing method. Perhaps an explanation of terms used in printing would better serve to illustrate how useful this seam is in printing operations. In printing, the chief advantage of the butted seam is that it prevents "scrimping" at the seam. Scrimping is caused by the seam pulling in to a width that is less than the normal width of the fabric. A "scrimp" is a crease in the fabric that starts at the seam and runs from 1 to 5 yards through the piece and parallel with the selvage. As the printing ink is applied to the face of the goods it does not get into or under the crease, and consequently when the fabric is finally pulled out to normal width a bare or unprinted portion is produced in the area previously occupied by the crease.

Concerning the butted seam in back gray material, since a butted seam is flat it does not in the majority of cases produce a "seam mark" on the printed piece. A "seam mark" is the imprint of the seam in the back gray left upon the printed piece. One also might mention that where scrimps develop in the back gray material they also leave their impression upon the printed piece in a similar way as in the case of seams.

Design of Furnaces and Fuel Feeders for Burning Refuse

By M. A. HOFFT,[1] INDIANAPOLIS, IND.

This paper includes a discussion of (1) a recent development in the design of a furnace for burning dry wood refuse in suspension; (2) factors influencing the design of wood-burning furnaces in industrial plants; (3) the development of inclined-grate furnaces for burning refuse fuels; and (4) the development of automatically controlled dry wood-refuse feeders and storage bins.

THE problems of refuse fuels are usually visualized, especially by wood industries engineers, as the burning of dry wood refuse from furniture plants, body plants, and sash and door plants with a moisture content varying from 6 to 10 per cent. Sometimes the problem includes the burning of sawmill hogged fuel with a moisture content of from 45 to 50 per cent; however, engineers engaged in the design of general refuse-burning furnaces are often expected to provide for the burning of unusual fuels. The wood refuse may have a moisture content as high as 65 per cent. There also are such fuels to be handled as bark from paper-mill logs, tanbark, sugar-mill refuse, fiber and pulp from palmetto palms, the refuse from brush making, and the wet coffee grounds from commercially operated percolators. The moisture content of some of these fuels runs as high as 75 per cent. Sometimes these installations are needed to dispose of a refuse that has been a nuisance; but often this refuse may furnish sufficient steam for the power and process requirements of the plant, and thus become a source of profit instead of causing expense for its removal. In consequence of the large range of problems presented, the design of refuse-burning furnaces is probably less standardized and there are more different conditions to be met than in any other branch of combustion engineering.

The early methods of refuse burning are too well known to require more than passing mention. Woodworking engineers are usually familiar with the flat-grate Dutch-oven setting for burning wet refuse in cone piles. These are still much in use and give fair results. There is also the flat-grate ordinary setting so typical of the furniture factory of a dozen years ago, where the sawdust and shavings were blown into the furnace from a cyclone and piled up unevenly on the grates, leaving many bare spots for cold air to rush through. Such installations are rapidly passing out of existence, and present methods in woodworking plants show much improvement. The amount of waste per unit of production has materially decreased, and the amount of power per unit of production has increased, until refuse that formerly was a nuisance has come to have such a monetary value as makes it profitable to use furnaces of higher efficiency and greater steaming capacity. Inefficient wood-refuse burning was inevitable so long as blowpipe collected refuse was irregularly mixed on the grate with hand-fed waste. A long stride in the right direction was taken when refuse hogs were introduced. It then became possible to grind assorted wood refuse to a reasonably uniform size and to distribute it evenly over the grate surface.

Burning in Suspension

Dry-refuse-burning furnaces are of two principal types—one for burning finely hogged dry wood and sawdust in suspension (this furnace resembles the regular pulverized-coal furnace) and the other burning refuse partly in suspension, but mostly on inclined grates.

The design of an outstanding burn-in-suspension furnace is outlined here to show its adaptability to certain conditions and to show some of the factors that enter into the decision as to which type of furnace should be used. The inclined-grate furnace is more adaptable to the average woodworking factory; hence it will be more completely discussed in this paper.

The burn-in-suspension furnace requires finely ground refuse that is fed in mechanically at a uniform rate and never blown in from a cyclone. This type of furnace is used for extensive woodworking plants where usually there are other boilers for burning an auxiliary fuel or where the auxiliary fuel, if burned in the same boiler with wood, is pulverized coal, gas, or oil. Fuels that are suitable for burning in pulverized-coal furnaces must be used. Raw coal, blocks, sticks, and rubbish cannot be burned in this type of furnace.

The burn-in-suspension furnace is rather expensive, requiring an unusually high boiler setting, with sufficient vertical distance to burn practically all of the fuel before it drops to the floor of the setting, and a large furnace volume for suspension burning, at least as large as is required for pulverized coal for the same ratings. This necessitates a building of corresponding size for housing this unusual boiler setting.

The maintenance of the refractory walls has been a big problem due to the high furnace temperatures and possibly to the erosion caused by the larger particles of fuel which drop part way to the bottom of the furnace and are picked up by the draft and carried back up to the boiler. The flying particles are doubtless partly responsible for the deterioration of these walls. Air-cooled hollow-wall settings improved the conditions materially. For some time after the development of the burning of dry wood in suspension it was thought that water-cooled walls could not be used because they would reduce the furnace temperature to the point where the refuse would not burn completely before dropping to the floor.

The water-wall setting illustrated in Fig. 1 has solved this problem. This setting is at the Mengel Company plant in Louisville, Ky., and is an excellent example of the burn-in-suspension furnace. It has three improvements over the majority

From 1897 to 1909 he was with the Chandler & Taylor Company, of Indianapolis, and then with the Hofft Company, of which he is the head. This concern has specialized in equipment for handling and burning all classes of refuse and low-grade fuels. Mr. Hofft has patents on stokers and flat arches.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

of the burn-in-suspension furnaces; first, the water wall; second, the hollow floor with air inlets to eliminate the piling of partly burned refuse on the floor; and, third, the location of the roof of the furnace relative to the first bank of tubes. The boiler was set sufficiently high in relation to the roof of the furnace to force a longer travel of the fine particles before passing the first baffle of the boiler. An early practice of this type of furnace was to put the roof of the furnace up near the top drum of this type of boiler. The Mengel Company design assures a more complete burning in suspension, even with the water-wall setting, and also prevents some of the carrying over of fine dust. The author spouts and is a factor in the success of the water-wall setting as it helps to maintain a higher furnace temperature. This also eliminates the puffing of the furnace and the possibility of back-firing into the bin. These boilers are 850 hp. each and easily develop 2200 hp. The auxiliary fuel is pulverized coal from a unit pulverizer.

Burning in Suspension Only Adaptable to Large Installations

The plants in which the burn-in-suspension furnace can properly be used are limited. Most woodworking plants are

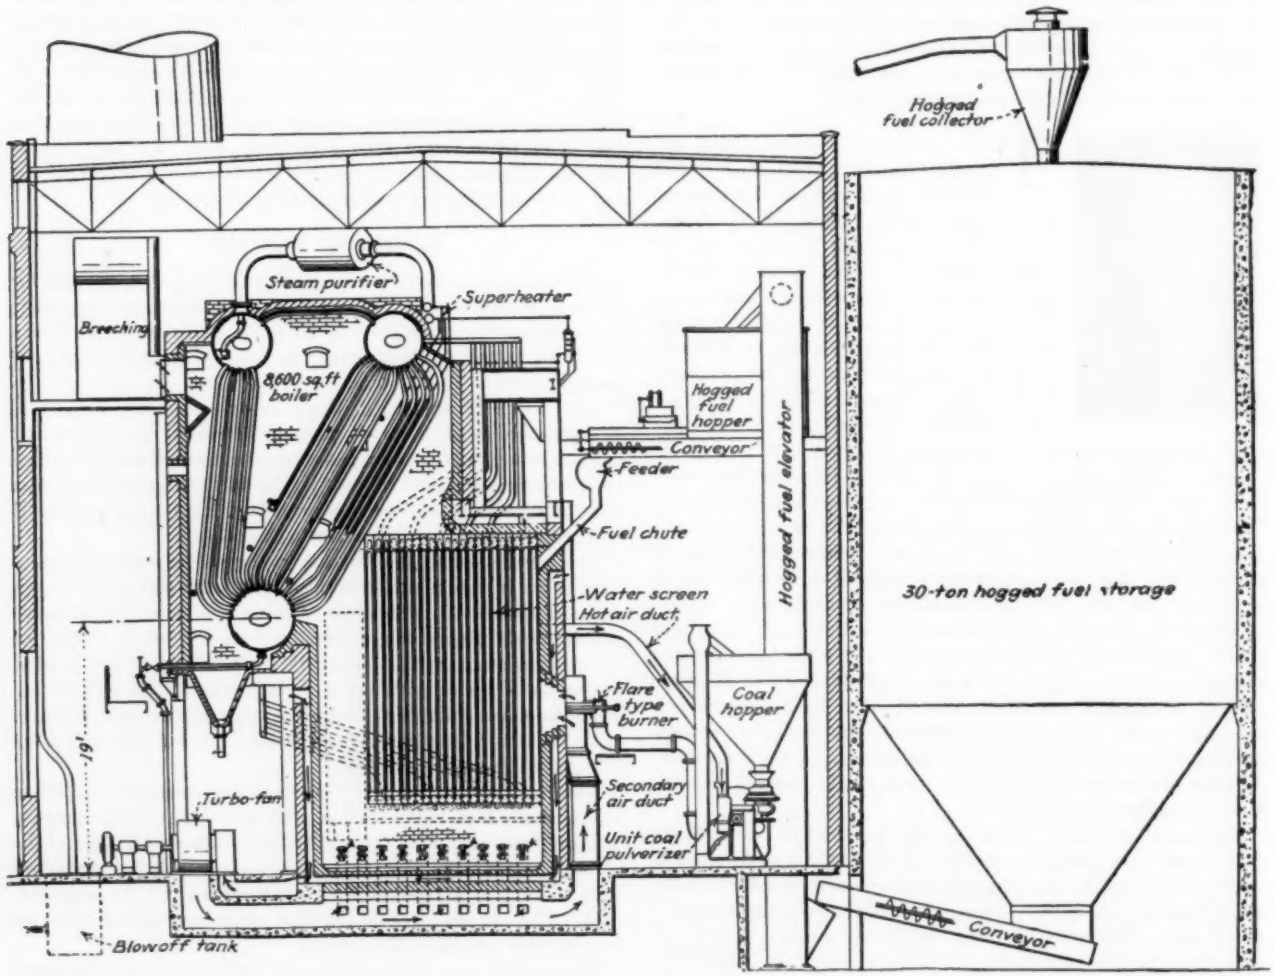

Fig. 1 Design of Burn-in-Suspension Furnace

(For burning kiln-dried refuse in suspension with water-cooled side walls and unit pulverizers for auxiliary fuel.)

believes that this furnace could be further improved by the introduction of air jets at high velocity through the nose of the arch. These small air jets, pointing down, would still further prevent carrying over and would give turbulence.

The sawdust, shavings, and hogged dry fuel are fed into this furnace from the storage bin by an automatically controlled screw feed. Instead of the fuel being delivered by the screws directly into the furnace, with charges of approximately a cubic foot of refuse per turn of the screw, it is fed from the screw through a rotary feeder, the rotary feeder breaking up these comparatively large charges of fuel into a fine spray, allowing an intimate contact of the air and fuel for complete combustion while in suspension. This prevents the introduction of cold air at the feed

not large enough and cannot profitably afford these settings and the equipment necessary for supplying the auxiliary fuel. Further, they must be able to burn blocks, sticks, and rubbish in case anything happens to the hog. The amount of edgings, blocks, and sticks that must be burned may be a fairly large percentage of the fuel. These plants are often unable to accumulate surplus refuse sufficient for holiday and shutdown periods, necessitating the use of coal at these times, even if not during regular plant operation. The installation of good furnaces and feeding equipment would save enough refuse in many of these plants for this night and Sunday firing; however, they must anticipate burning raw coal during holidays and shutdown periods. There also are many plants where the moisture content of the

fuel may be too high or the hogging too coarse to permit burning-in-suspension. For such plants the author has for a number of years been developing the inclined-grate furnace, described herein in detail.

Inclined-Grate Furnace

The inclined-grate furnace does not require the large furnace volume necessary for burning in suspension, since only the fine dust burns in suspension, the larger particles burning on the grates, producing excellent results even on low-set boilers. Fig. 2 illustrates the setting for three 500-hp. boilers. The first boiler in this battery ran a large part of the time for a couple of years at around 300 per cent of rating as it was the only boiler in the plant. In emergencies, steam was obtained from another factory across the railroad track. When the plant was enlarged, two additional boilers were installed. This setting has always met all the requirements of the Smoke Inspection Department and did not have an excessive maintenance cost. A large part of the maintenance cost on this type of setting when operating at a high rating is in the repair to the bridgewall. Some water bridgewalls have been installed with excellent results, holding down the furnace temperature slightly. Water-cooled side walls would be very desirable and would eliminate the maintenance on refractories.

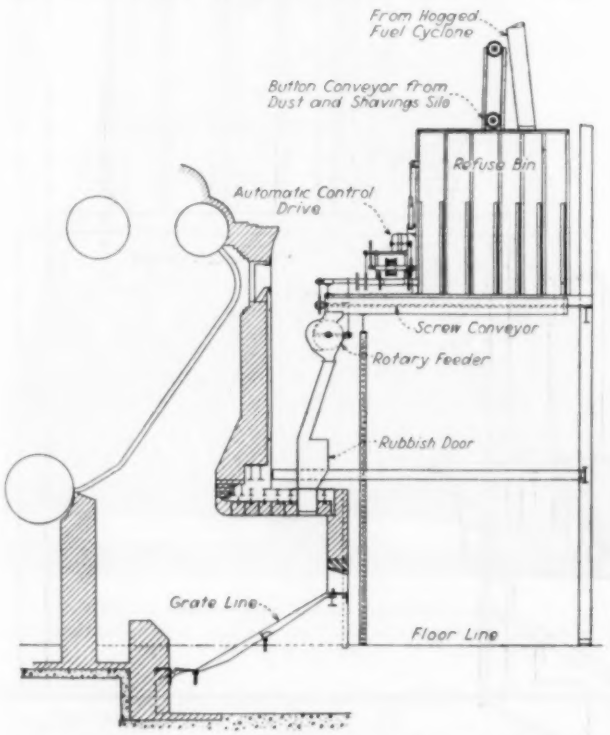

Fig. 2 Dry-Refuse Furnace, Showing Method of Feeding
(Rubbish is fed by hand through the roof of the arch and hogged fuel with an automatic feeder.)

When this plant was operated on one boiler, there was no hog in use; the blocks and sticks were fed through the roof of the arch to the grates, being shoved through a balanced rubbish door. Sawdust and shavings were fed through the same opening in the arch by means of the same type of automatically controlled feeder. During holidays and shutdown periods raw coal was used for fuel. The coal was fired either through the rubbish opening above the arch or through the firedoors as desired. It was fired on the top end of the grates, and the coking method of operation was used. In firing coal these boilers are easily operated at about 125 per cent of rating. The plant now has hogging equipment in use. The hogged fuel is fed through the automatic feeder. The furnace volume on this is 1280 cu. ft., or 2.53 cu. ft. per rated horsepower. The arch on this setting is 18 in. higher than standard.

When this type of furnace is run at high ratings, it is necessary to introduce extra over-air, especially when being fed with the automatic feeder shown, as there is little air admitted with the fuel. Over-air is introduced through a ratchet-operated vent door in the firedoor, or if battleship doors are used, they are tilted slightly. Air admitted in this way is forced by the arch to mix with the gases before coming into contact with the boiler, so there is no appreciable loss in efficiency. The CO_2 may be maintained approximately as desired. However, when resinous woods are used for fuel, it will smoke at approximately 12 per cent CO_2. Oak and similar wood refuse may be fired with a higher CO_2 without smoke.

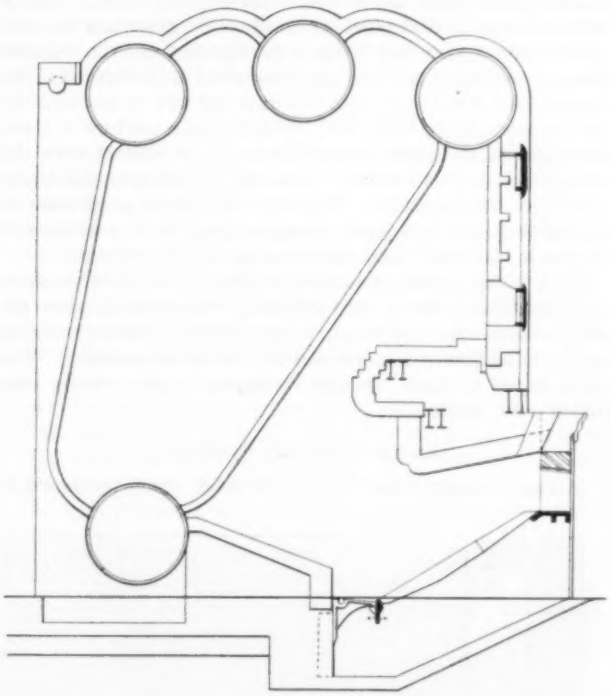

Fig. 3 Efficient Smokeless Dry-Refuse Furnace
(This has an extremely small furnace volume.)

Low Boiler-Setting Installations

While it is not desirable to set a boiler low and a good furnace volume is desirable, it is possible to get smokeless and efficient results with a low setting and restricted furnace volume. The setting illustrated in Fig. 3 is for four 350-hp. boilers at the plant of the M. B. Farrin Lumber Company in Cincinnati. These boilers had been in operation with flat grates for a number of years. Large quantities of charred and partly burned fuel were being carried out of the stack and deposited over the surrounding buildings, causing complaint and legal difficulties, not only with the Smoke Inspection Department, but with the neighbors. It was impossible to raise the boiler, or to make an extension Dutch oven or to lower the floor. The furnace, as illustrated, was installed, and it completely eliminated the carrying over, and incidentally was enough more efficient to make it unnecessary to use coal as an auxiliary fuel. Approximately

$8000 worth of coal had been used each year. These boilers have often operated at 200 to 250 per cent of rating, and normally at 150 per cent of rating, to the entire satisfaction of the Smoke Inspection Department. One would expect to have a high maintenance cost on this restricted setting, but the reverse has been the case. The inclined-grate setting has been in service for 10 years, and the maintenance cost for brickwork and furnace castings for the last three years on these four 350-hp. boilers was $1879.08 for materials and labor.

The furnace volume on this setting is 586 cu. ft., or 1.67 cu. ft. per rated horsepower. This is outlined here to show that unusual results may be obtained even with small furnace volume. This is due to the fact that the fuel is burned on the grate and the arch construction is such that it forces the fine dust and the volatiles that are distilled off the fuel that is deposited at the top end of the grate to pass down over the hotter fuel bed and to mix with the thinner gases at the lower end; thus forcing a mixture of these fine particles and gases before they come in contact with the cooling surface of the boiler. The arch on this setting is about 1 ft. lower than standard. This was done partly on account of limited headroom and partly to more surely force a mixture of the gases, and rather high maintenance cost was expected.

There is also another installation of 500-hp. boilers of the same type and which are set very similarly, with approximately the same results. As mentioned, these restricted furnace volumes are not to be desired, but are used only in case of necessity. The refuse is fed to these furnaces through an automatically controlled screw feeder.

Return-Tubular Settings

A return-tubular boiler setting for small plants is shown in

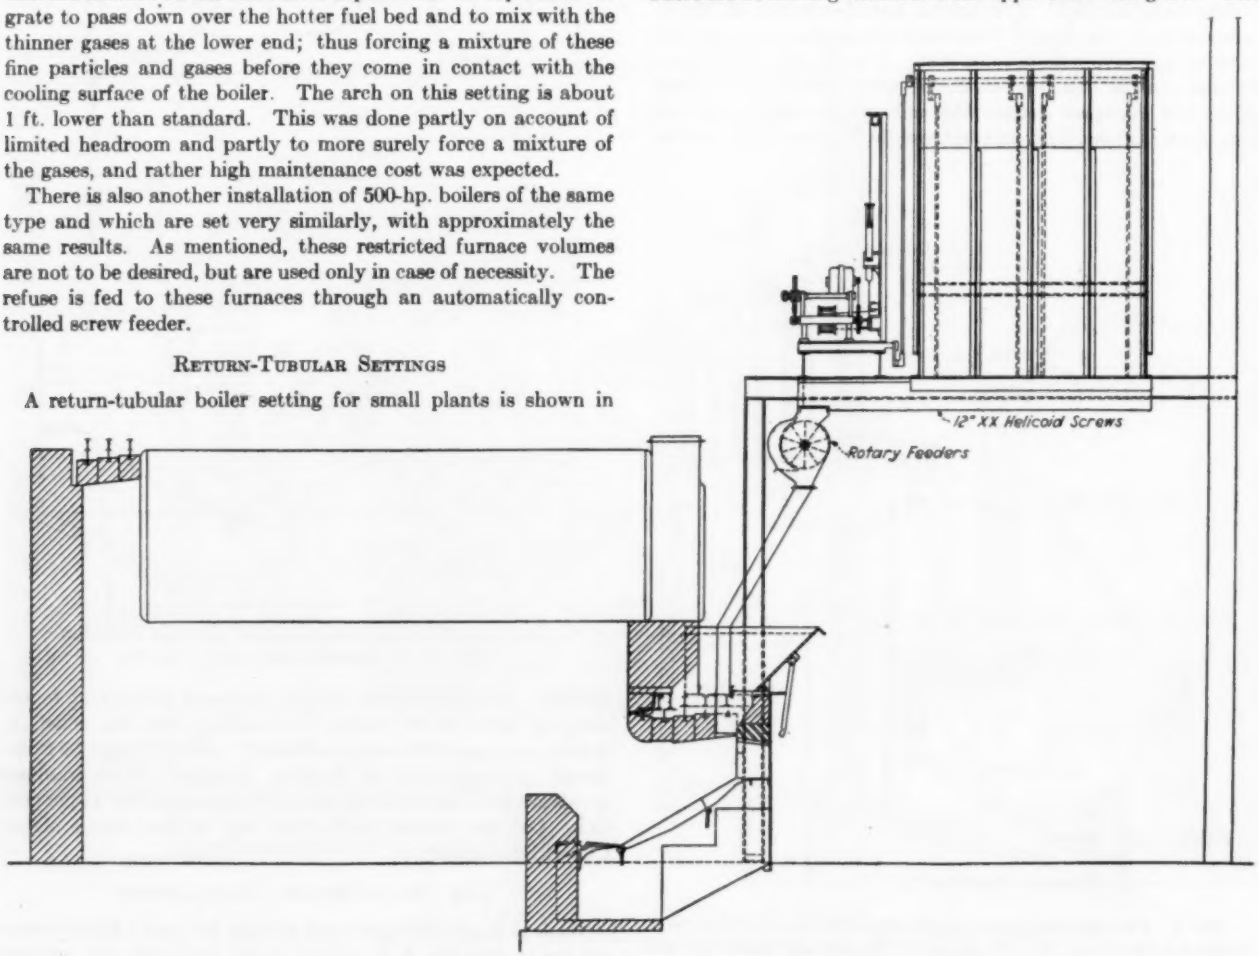

Fig. 4 Furnace for Return Tubular Boiler
(This shows the method of feeding coal and wood refuse through double-feed spout.)

Fig. 4. This illustrates the method of feeding coal through the top of the extension Dutch oven on the inclined-grate furnace. With this setting there is a coal hopper on top of the extension Dutch oven and a double-opening feed spout extending through the arch to deliver the fuel to the top end of the grates. Sawdust shavings, and hogged fuel are fed through an automatically controlled screw conveyor delivering the fuel through one of the openings in the double-opening feed spout. Coal is fed through the other opening of the same feed spout by means of a slide gate which drops it through the arch. The rotary feeder in the automatic feeding device makes an air seal between the feed bin and the furnace. The slide gate permits dropping the coal from the bunker to the top end of the grate when needed and also shuts off the air from the coal bunker. The coking method of firing the coal is used. The firedoors below are still available for firing coal or for blocks and sticks if desired. The firing of the blocks and sticks in this type of furnace is much like throwing them into a hole, as they drop to the rear end of the grates and it is not necessary to shove them through a cone pile of wood as in the case of a flat-grate setting.

Grate and Dump Construction

The construction of the grate, fuel pusher, and dump is shown in Figs. 5 and 6. The grates are longitudinal and stationary, and for dry wood are set on an incline of approximately 30 deg. There are no moving elements in the upper end of the grate. The air spaces at this point are horizontal, so as to prevent dripping of fine fuel into the ashpit. The lower section of the grates is provided with two to six rows of fuel pushers, depending on the length of the grate. Each row of pushers is individually operated from the front by a separate lever. Since the grates are longitudinal and stationary, there are no projections or cross-ridges to hold up the fuel. The refuse fuel deposited at the upper end slips slowly down the grate as it burns, avoiding the necessity of shoving the refuse fuel down the grate. In burning refuse fuels it is very objectionable to agitate the fuel bed, especially at the upper end. This agitation is eliminated with this type of grate.

With the proper angle to the grate, the fuel does not avalanche and make a big pile at the bottom.

There are dumps at the lower end of the grates for the removal of ash. The cleaning of the fire is accomplished by raising the lower row of pushers operating between the stationary grates and dropping the dumps.

The raised lower row of pushers prevents the slipping of good fuel into the ashpit and at the same time kicks off the ash and clinker through the dump opening. The fuel bed on the main body of the grates is not disturbed in this operation. The fuel pushers are 12 in. long and travel through between the stationary grates approximately 10 in., which is ample travel to kick off the ash and clinker without the necessity of poking through the cleanout doors. The dump openings are the full width of the furnace, having no bar across the opening to hold up the ash and clinker. Any sand slag that may be formed will be on the lower

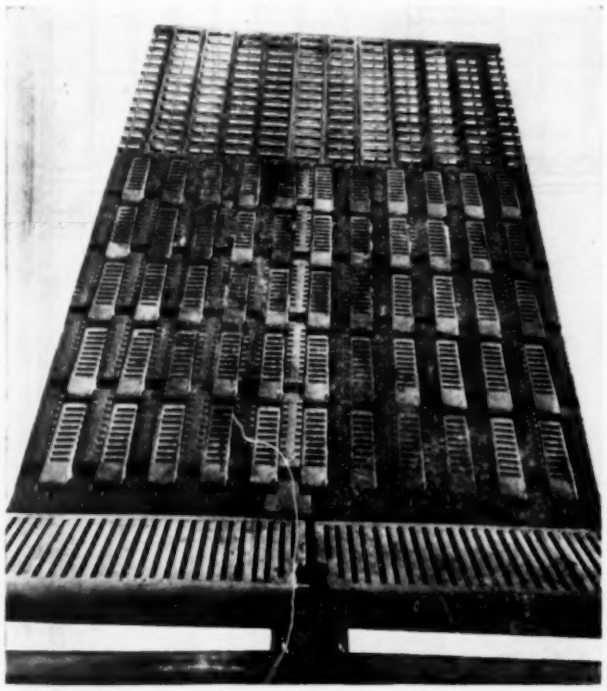

FIG. 5 STATIONARY GRATE CONSTRUCTION
(This has horizontal air spaces in the upper section and fuel pushers in the lower section.)

section of the grate and is removed by the operation of the other rows of pushers.

When clean wood refuse is being burned, the cleaning and pusher operation is only occasional, usually once in several days. At that time it is often advisable to keep the lower end of the grates covered with ash so that the air entering the furnace will be forced to enter at the upper end and mix with the gases under the arch, and not be allowed to short-circuit through the lower end of the grates or dumps. If it becomes necessary to use coal for the auxiliary fuel, this ash can be dumped out quickly and the coking method of firing coal used. The coking method of firing coal and the arch construction which forces the volatiles to travel down over the fuel bed make a practically smokeless fire, even with high volatile coal. Of course with coal firing it is necessary to use the fuel pushers and dumps more frequently, their use depending on the kind of coal and the rate of firing.

It is best to fire coal and wood refuse separately. When firing both at the same time, the temperature created by the burning wood on top of coal will fuse the ash and cause heavy clinkers unless the coal has a high fusing ash.

The illustrations, of course, show but a few types of boilers. There are a great many of these installations under all types of boilers and operating under varying conditions. It is usually possible to very greatly increase the capacity of the boiler, sometimes doubling the previous capacity; also to get practically smokeless operation. The increased efficiency obtained from the available wood refuse is often sufficient to eliminate the use of coal.

The tendency now in designing boiler plants for woodworking industries is to design a boiler setting for the highest possible efficiency on the major fuel, which is wood, and not to burn the wood in a furnace designed for the auxiliary fuel, coal. This often means that very little, if any, coal is needed.

WOOD REFUSE FEEDERS

The result from any refuse-burning furnace largely depends on the feeding method. With the old method of feeding, sawdust and shavings were blown from a cyclone directly into the furnace as they were made in the factory, regardless of the needs for steam. The furnace would be flooded with shavings at one time, and in a few minutes it might become necessary to put in coal, often the cyclone blowing in nothing but cold air. This led to the development of equipment for regularly feeding the refuse to the furnace; first, the use of the chain drag and, later, the automatically controlled screw feeder. In handling the dry refuse with the screw feeder, the sawdust, shavings, and hogged fuel are blown into a bin and fed to the furnace by means of heavy screws, the speed of these screws being controlled by the steam pressure.

The early problems of this method of feed were, first, the fire

FIG. 6 DUMP AND FUEL PUSHER OPERATION FOR CLEANING FIRE

risk caused by possible backfiring and puffing of the furnace and, second, the arching of the fuel in the bin. The first problem was overcome by the use of a rotary feeder between the end of the feed screw and the furnace. This made an effective air seal, keeping any back draft and any sparks and backfire from getting to the bin. In addition to this it shut out the air entering the furnace with the feed, which air was found undesirable. It was found also to effectively break up the comparatively large charges of fuel delivered by the screw spreading it more evenly in the furnace. The second problem, the arching of the fuel in the bin, was overcome by the use of a bin with a flat steel bottom and either vertical or slightly tapering sides. The bottom of this

bin is practically covered with a series of heavy helicoid screws. A typical installation of this kind is illustrated in Fig. 7. The screws covering the bottom of the bin are connected in series of three, any series or all the screws may be operated as desired. These screws slip the fuel forward into a trough extending at right-angles to the screws. This slipping forward and the slight agitation caused by the turning of the screws effectively overcome the tendency of the fuel to arch, even with the use of coarse hogged fuel and ground veneer strips having a considerable quantity of long slivers. These bins have been built as large as 7000 cu. ft. capacity, and there seems to be no reason why bins of much larger capacity cannot be built without arching.

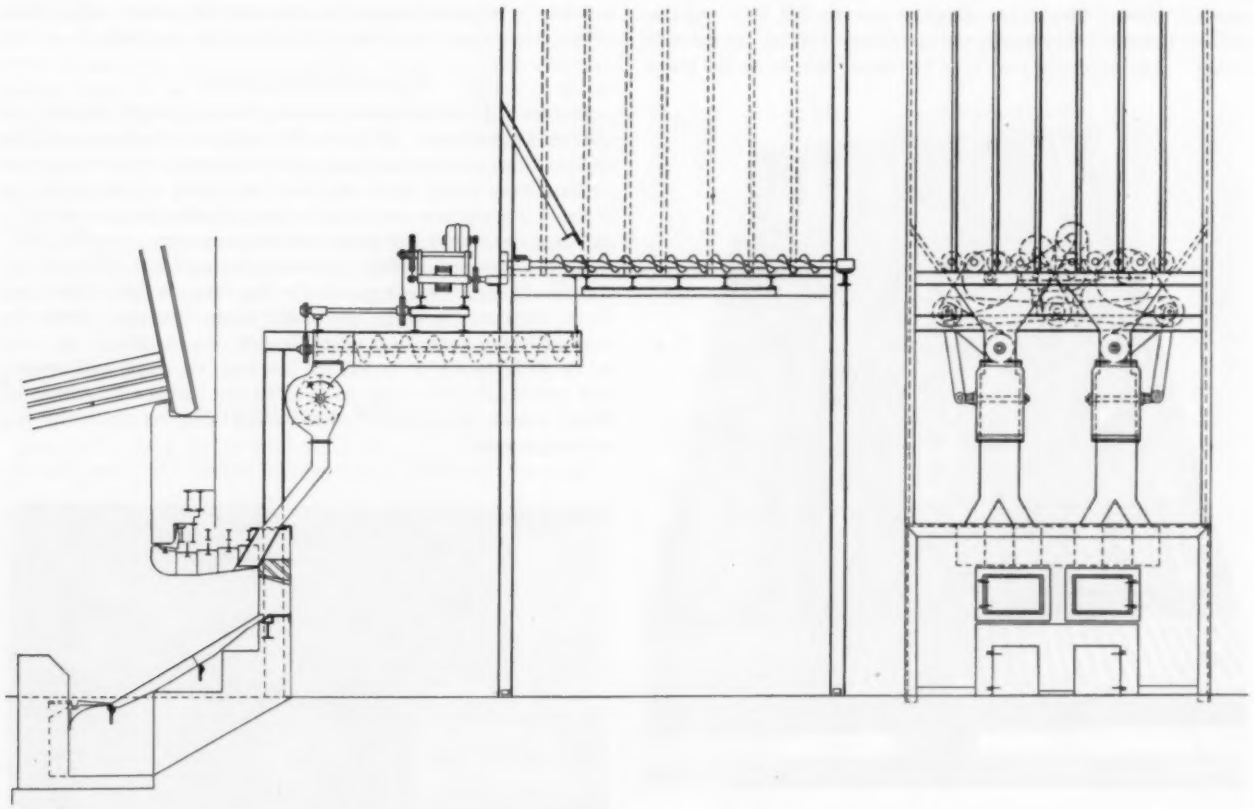

FIG. 7 AUTOMATIC SCREW FEEDER WITH SCREW BOTTOM BIN
(This prevents the arching of hogged fuel.)

This feeding equipment, even for large boilers, is driven by a 3-hp. constant-speed motor driving through the proper reduction gearing a variable-speed transmission. The arm controlling the variable-speed transmission is connected to an automatic pressure-control valve, which moves this arm back and forth, controlling the speed of the unloading screws on the bottom of the bin, and it is able to so control this feed as to hold the steam pressure to within 3 or 4 lb., even with a widely fluctuating load, the speed of the unloading screws on the bottom of the bin being controlled by the steam pressure. The capacity and the speed of the lower feed screws and rotary feeder are sufficient to prevent the fuel from accumulating in the trough, avoiding the possibility of plugging up the feed screws or the rotary feeder. The sides of the rotary feeder are counterbalanced so as to discharge any blocks or pieces of metal that might accidentally get into the machine. A small steam engine may be substituted for the motor, in which case it is advisable to control the speed of the variable-speed transmission rather than by throttling the engine, as the control is closer and the operation more satisfactory.

The automatically controlled screw feeder is not well adapted for burning wet refuse, as the quantity of fuel to be handled is very great and heavy, and there is no fire risk in connection with its handling. This class of fuel can be handled with much lower cost and as satisfactorily with an ordinary drag conveyor in which the control of the feed is accomplished by controlling the depth of the fuel on the grates, as will be described.

FACTORS IN THE DESIGN OF THE FURNACE

In the design of the furnace for burning these widely varying fuels, the moisture content, of course, is the first consideration. The heat value of the fuel, the size of the particles of the fuel as delivered to the furnace, the freedom with which the fuel burns, the tendency to pack densely on the grate, the draft conditions, and the capacity desired are a few of the factors that enter into the design of furnace.

The angle of the grates for this wet refuse varies and is from 30 to 50 deg. The length of the grates also is determined by the moisture content and rate of firing and the width of the boiler setting. The length and contour of the arch also are governed by the same factors. The depth of the fuel fed at the top end of the grate is governed by the nature of the fuel, coarse-ground wet hogged wood refuse requiring about 18 in. of fuel at the top, sawdust about 15 in., and other fuels varying up to bagasse, which requires about 3 ft. 6 in. of fuel at the top end, on account of its being light and porous.

For this type of furnace the volume in the firebox proper need not be as great as on the old-style Dutch-oven furnace because the inclined-grate furnace firebox is really a gas producer, com-

bustion being completed more in the back combustion chamber than is the case of the old-style setting.

It is very necessary to have as much refractory surface as possible to keep drying out the incoming refuse and to help drive out and ignite the volatile gases. In order to accomplish this it is advisable to use two or more furnaces for wide boilers. Boilers of 700 hp. and larger have been equipped with three furnaces per boiler, and settings are now being designed for 1200-hp. boilers with four furnaces to the boiler. This multiple-furnace construction is obtained by building the grates in sections and putting refractory division walls between the sections, not only giving the additional refractory surface needed, but causing the fuel fed to the top end of the grates to spread evenly over the entire section, overcoming the tendency to have thick and thin strata down the grate. With this furnace the cleaning of the fire is done so quickly on each individual section that there is practically no loss of steam during the operation. The ash and clinkers are dumped into the ashpit by the dumping and pusher operation described for dry-refuse furnaces.

Any sand slag that may be formed on the grates is usually formed on the lower or pusher section and is quickly removed by the operation of the fuel pushers between the stationary grates.

It also is possible to operate with one section of the furnace idle or to burn one class of fuel on one section of the grate and another on the other section of the grate. When one section is being cleaned, the draft is shut off of that section, preventing the cooling down of the furnace by the incoming air.

Grate Design

Longitudinal stationary-grate construction with fuel pushers operated between the grates at the lower end has overcome the difficulties with the early inclined-grate furnace. These early furnaces were known as a stepladder design and had grates extending crosswise of the setting, which had a tendency to hold up the fuel and keep it from sliding evenly down the grate, thus developing holes in the fire and causing some avalanching of the fuel.

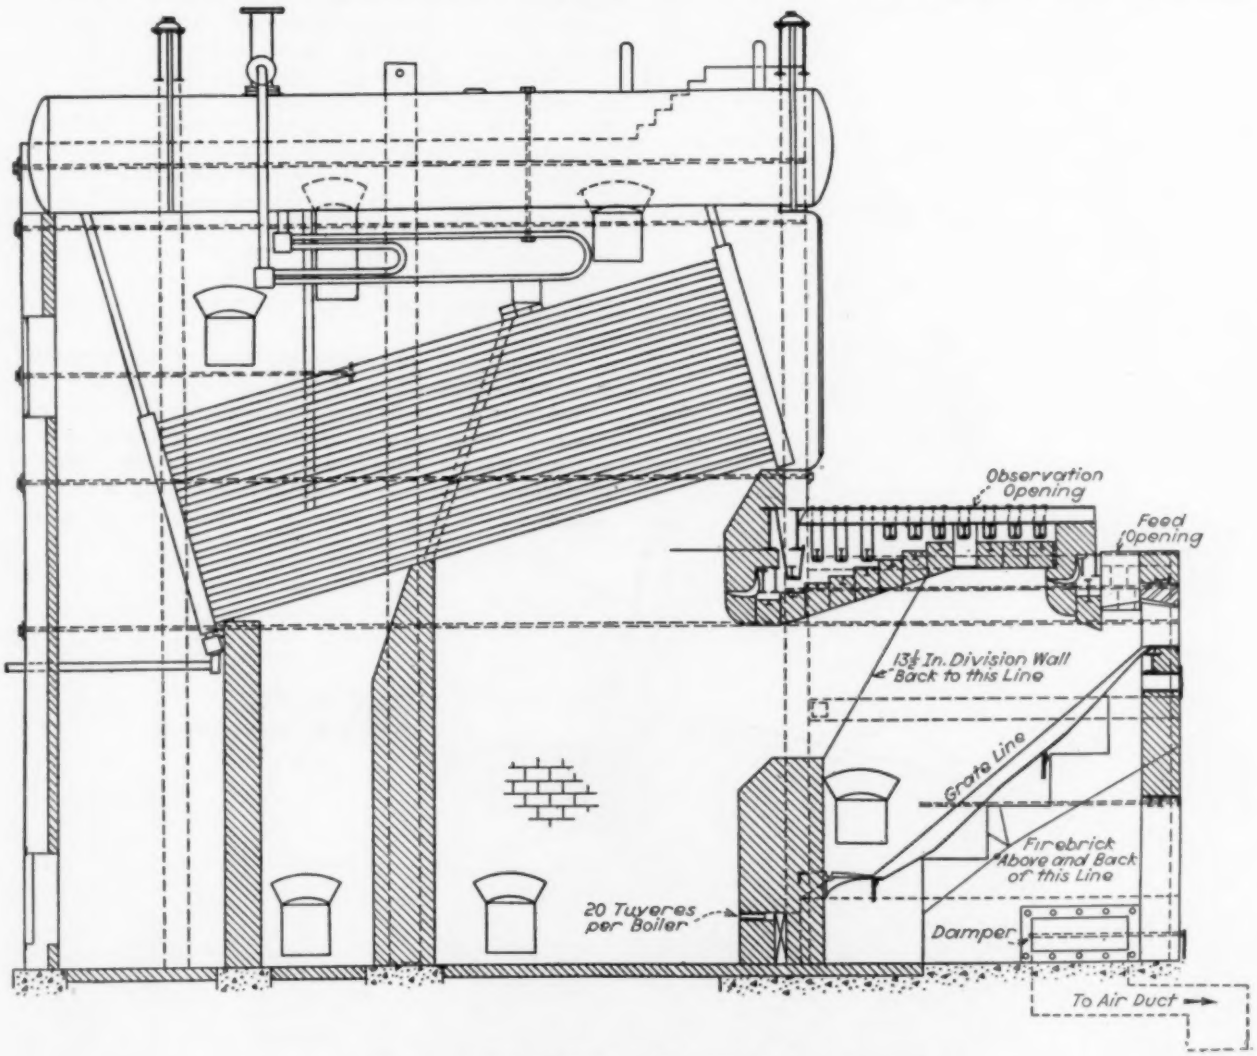

Fig. 8 Typical Design for Sawmill Hogged Fuel

Design for Wet Hogged Waste

A typical setting for burning a good quality of hogged fuel of 45 per cent moisture content for a 600-hp. boiler to operate at 160 per cent of rating is illustrated in Fig. 8. The depth of the fuel bed at the upper end of the grate is regulated by the location of the feed opening in the arch; the arch is then stepped up in as

short a distance as possible to allow the radiation to strike the drying pile of fuel as quickly as possible and to get ignition high up on the pile of drying fuel. The arch is extended back over the grates to just past the bridge wall, and the nose of the arch is dropped at the bridge wall. This arch contour is to force a mixture of the heavy volatile gases distilled off the drying pile with the hotter, lighter gases rising off the lower end of the grate. These gases are finally burned in the combustion chamber back of the bridgewall. The angle of the grate is 40 deg., the furnace volume in the furnace proper is 680 cu. ft., the volume of the back combustion chamber is 2058 cu. ft. This setting is provided with dampers for forced draft. Forced draft is used at the higher ratings. Tuyères are placed in the bridgewall for air at this point.

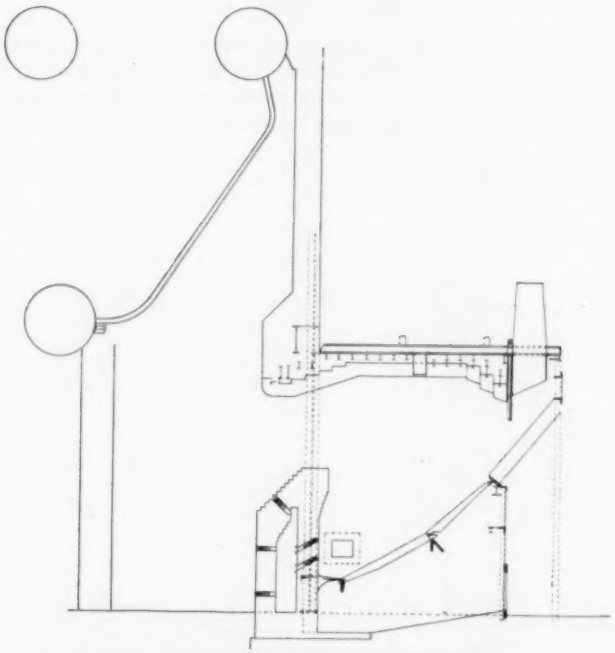

FIG. 9 DESIGN OF FURNACE FOR VERY WET HOGGED FUEL OR BARK

A furnace designed for a wetter fuel and to operate at higher ratings is illustrated in Fig. 9. Under these conditions it is not possible to get sufficient air through the fuel bed to get double rating even with forced draft, as the draft will pick up the fuel and carry it over the bridgewall. This setting also is a 600-hp. boiler. The grate area is much longer than on the furnace for drier fuel. In this design the fuel is dropped on a refractory hearth, the thickness of the fuel bed being regulated by the gate. When once regulated to the fuel to be used, this gate need not be moved unless the class of fuel is changed, the steam output of the boiler being controlled by the air damper. This refractory hearth is set on 50-deg. incline. The next section of the grate is stationary, with horizontal air spaces, and is set at approximately 45 deg. This change in angle is made because the fuel is slipping more freely this distance down the grate. The lower section where the fuel pushers may be operated between the grates is set at approximately 30-deg. incline. This change in angle is to prevent the possibility of too heavy a fuel bed at the bottom and on the dump at the lower end. With this furnace the bridgewall is tilted forward to force the lighter, hotter gases from the lower end to mix better with the heavy volatile gases from the drying pile of fuel at the top end.

Provision is made for a large quantity of over-air or auxiliary air through air ports placed through both the front and rear faces of the bridgewall, and air openings also are provided in the side walls above the grates. This very materially assists in speeding up combustion, especially if this air is put in under pressure. Suitable dampers are provided at these air openings so that the auxiliary air may be used as desired. The air ports through the back face of the bridgewall are to burn any unburned particles that may carry over the bridgewall. With some fuels it is practically impossible to get sufficient air through the fuel bed. It is also inadvisable to allow the air to enter with the fuel on account of cooling down the arch. This is the reason for putting the air

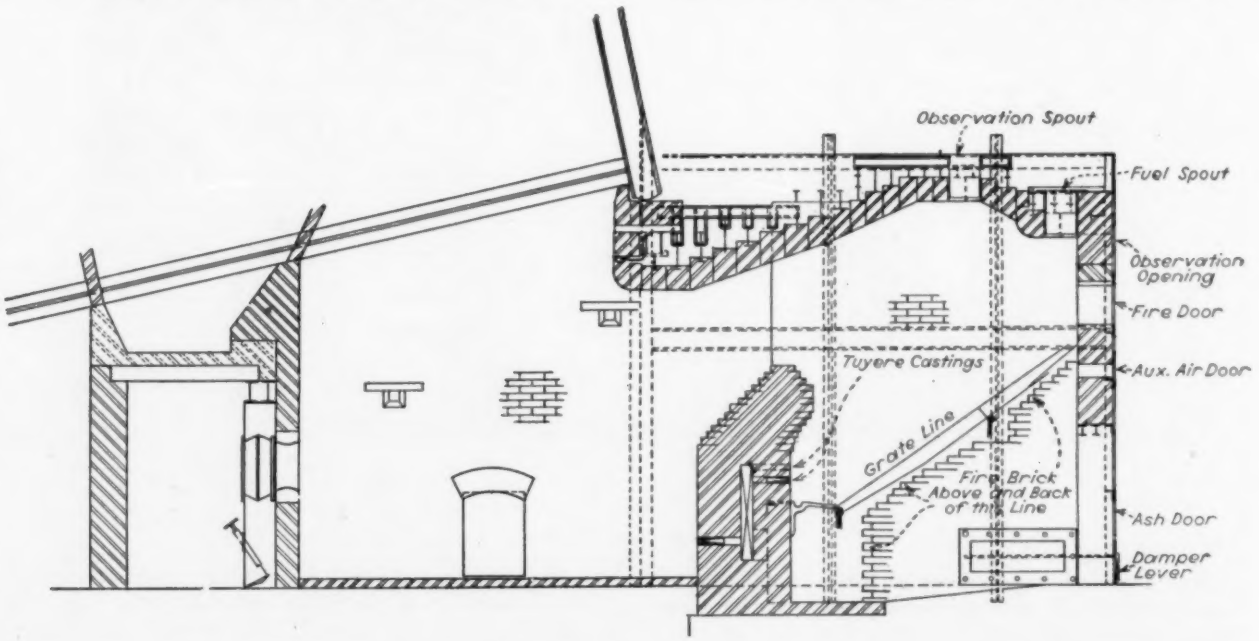

FIG. 10 TYPICAL DESIGN FOR BAGASSE FURNACE
(This shows the oil burners in the rear bridgewall.)

through the sides and bridgewall, preferably under pressure. This gives the necessary turbulence to speed up combustion. The regulated fuel depth and control of the air permit the operation of this furnace at very high CO_2, and almost all of these furnaces will be found operating at from 14 to 15 per cent CO_2. It is possible to get a higher CO_2 on wet refuse without deterioration to the refractories than on dry. On dry refuse a very high CO_2 of course is very hard on refractories. For wet refuse it is not possible to obtain sufficient temperature in the furnace to seriously damage the refractories, and these furnaces will run for years without any maintenance on the furnace, probably due to the fact that the highest temperatures are in the combustion chamber and not in the furnace proper.

Furnace for Burning Bagasse

A typical setting for burning bagasse refuse from cane-sugar mills is shown in Fig. 10 and Fig. 10a. This setting is for three 900-hp. boilers with multiple furnaces, three furnaces to each boiler. As this plant is also a sugar refinery requiring more steam than for the making of raw sugar, provision is made for the use of oil as an auxiliary fuel. This oil is fired through the back bridgewall as shown. This furnace may be operated on bagasse with natural

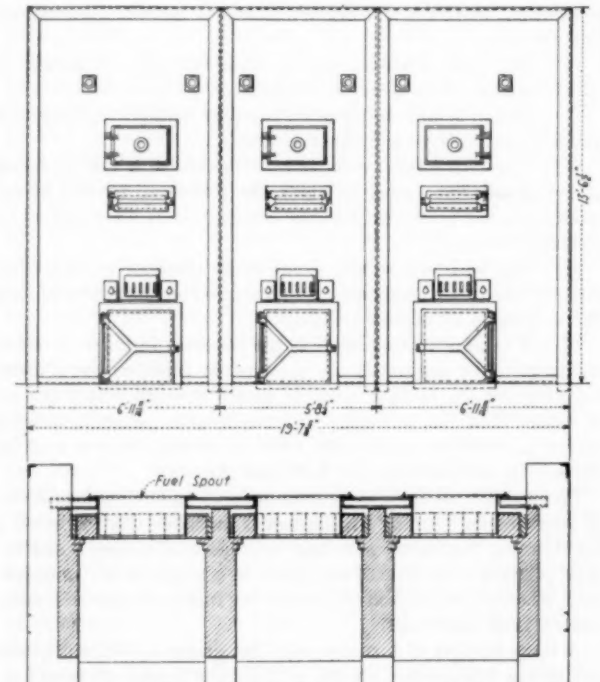

Fig. 10a Cross-Section Through Furnace as Illustrated in Fig. 10, Showing Multiple Furnaces

draft at 150 per cent of rating, and with forced draft it will run 200 per cent of rating or more. The forced-draft air connections are through the bottom of the division walls, with dampers arranged so that the air may be blown to any or all of the divisions of the furnace.

Bagasse is a light and porous fuel requiring a heavier fuel bed and has a greater tendency to burn holes in the fire than has wood. The multiple-furnace construction and grate design have solved this problem of keeping an even fuel bed across the grate. The small opening in the top of the arch, as shown in the illustrations is a treadle-operated observation door over each division of the furnace.

The setting illustrated in Fig. 11 was originally designed for burning a large quantity of very wet coffee grounds of about 75 per cent moisture content to be used with about 20 per cent coal. It was found that with the addition of the coal too much steam was made. The furnace was altered by dropping the feed-spout openings as shown, to regulate the fuel depth to the proper height, and the bridgewall was altered to give more refractory and to create the proper throttling effect between the arch and the bridgewall to bring up the furnace temperature. This alteration permitted the operation of this furnace on the coffee grounds taken from the percolater without the use of the auxiliary fuel. There are 17 or 18 tons of coffee grounds burned per day on one of these furnaces for a 150-hp. boiler.

Other extremely wet fuels and fibers are burned. In some cases where the waste fuel burned is not sufficient to supply the steam required for the operation of the plant, coal is used as an auxiliary. For extremely wet fuels this coal is put on the dumps through a side opening and acts as a backlog to help bring up the furnace temperature. This makes possible the burning of any refuse that is combustible.

Conclusion

In the designing of the furnace for efficient dry-refuse burning consideration should be given the moisture content of the fuel,

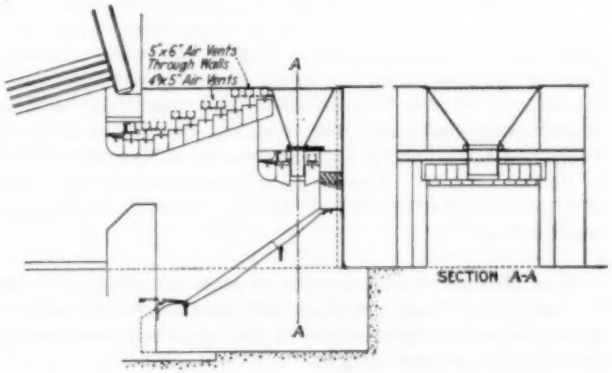

Fig. 11 Furnace for Burning Extremely Wet Refuse
(This design takes care of material from distillation or cooking processes.)

the fineness of the hogging of the fuel, the disposition of the blocks and rubbish, the kind and quantity of the auxiliary fuel, and the method of handling and firing the auxiliary fuel. For both fuels it is very essential to have an even and controlled feed of the fuel.

In designing a furnace for burning wet refuse the first consideration is the moisture content of the fuel; consideration also must be given to the size of the fuel as delivered to the furnace, the type of boiler, the density with which the fuel packs on the grate, its burning qualities, the draft conditions, and the rating desired.

The tendency in recent years in designing furnaces for industrial woodworking plants has been more to design the furnace to burn the major fuel with the highest possible efficiency, and in this way to reduce the auxiliary fuel to the minimum, and to use a furnace that is adapted also to the burning of the auxiliary fuel available.

Discussion

H. W. Brooks.[2] My own experience while connected with the design and operation of about 300 power plants has included 5 wood-burning plants. This led to the conclusion that the utilization of wood as a fuel was a rather insignificant matter when compared with some of the other energy sources in the United States with which we are more familiar. It has been, therefore, a cause of great astonishment to happen across a chart furnished by the United States Geological Survey which shows the sources of energy in the United States. This gives 0.1 per cent for wind power, 2.5 per cent for animal power, 6.3 per cent for water power, 5.5 per cent for firewood, 8.1 per cent for anthracite coal, 50.3 per cent for bituminous coal, 21.4 per cent for oil, and 5.8 per cent for natural gas. It is astonishing to learn that firewood produces, according to this chart, nearly 80 per cent as much energy as is produced in the United States by water power. It is almost unbelievable that firewood produces around 70 per cent as much energy in the United States as does anthracite and that firewood produces approximately as much of the total American energy as the total of natural gases.

There is hardly a subject whereon dependable data are less available than the utilization of wood and wood wastes as fuel. The statistics of the Geological Survey show that it is a hugely important subject, yet the bibliography is woefully lacking. There are a few publications along the general line, most of them obtainable through the courtesy of the National Committee on Wood Utilization of the Department of Commerce. The Bureau of the Census has included wood fuel in its 1929 schedule, but these figures will not be available for a year or more. In the October issue of *Combustion* there is an article by A. R. Smith, of the Combustion Engineering Corporation of New York, entitled, "The Utilization of Waste Wood for Steam Generation," which may be of some interest. The Forest Products Laboratory, of Madison, Wis., has issued two technical notes under the subjects of "Fuel Value of Wood" and "Fuel Value of Wood Waste Overestimated." The National Committee on Wood Utilization has a bulletin entitled, "Survey of Nonutilized Wood in North Carolina." There is a particularly interesting bulletin of the same committee entitled, "Sawdust, Wood Flour, Shavings, and Excelsior."

Sern Madsen.[3] This paper approaches the subject of refuse burning from a broad viewpoint and gives due consideration to all the individual characteristics of the fuel to be burned and the size and type of plant using it.

Referring to the burning of dry fuel as accumulated in most of the furniture factories, body plants, sash and door factories, etc., it has not generally been appreciated what economies can be effected by using the proper types of furnaces and feeding equipment for burning this refuse.

Old customs have influenced these industries in the belief that wood refuse was something to be disposed of rather than to be used as a valuable fuel. It is not generally appreciated that this dry fuel when burned on proper grates, with ideal admission of air through the fuel bed, produces a fire of such intense heat that it requires that special attention be given the refractories. It is highly desirable that some of the water- or air-cooled side walls, arches, and bridge walls developed for central-station operation should be adapted for use in furnaces burning dry refuse. Installations which have been designed for maximum efficiency produce intense temperatures far above those thought possible a few years ago.

The woodworking industry has improved its production machinery until it compares very favorably with that used in the metal-working industries. Now let us get the utmost out of the valuable fuel which has formerly been called and treated as waste. It is not unusual for these installations to pay for themselves by the savings made the first year. This is indeed a happy opportunity—to make improvements that not only pay their way but that produce dividends.

W. E. Allington.[4] The author has stated many interesting facts in connection with the subject, but he has, perhaps inadvertently, made some misstatements and omitted others and has not given a clear understanding of the principles of suspension burning and furnace design, type of grates, and automatically controlled wood-fuel feeders and storage bins.

These subjects have ramifications which run into almost endless complications, and with an experience of over forty years, the writer still is learning and still is coming in contact with problems that present new factors which need special consideration. A full treatment of these subjects so far as now understood would require a book instead of a short discussion such as contained in the paper, and no doubt it was difficult to know just what problems to discuss and where to leave off.

Instead of two types of furnaces for burning wood fuel in suspension, there are at least five principal types of furnaces, as follows:

(1) One with large combustion chamber without grates, of which General Motors and subsidiaries have over twenty.

(2) One with large combustion chamber with grates of various kinds, including several inclined grates.

(3) One with smaller combustion chamber with various forms of practically flat grates in which the fuel is all ignited before landing on the grates so that the combustion is not confined to surface burning.

(4) One with still smaller combustion chamber in which the inclined grates are used and the fuel is piled on the grates so that the burning is all surface burning.

(5) A type of furnace such as the Stratton furnace, in which the large upper portion of the combustion chamber has a lower tapering portion leading down to grates through which the air is heated and fed upwardly at considerable velocity, holding heavy particles in suspension which otherwise would land on the grates and be consumed with less efficiency.

Information on the evaporation secured in the various forms of furnaces for burning in suspension indicates that for such a fast-burning fuel as dry shavings, sawdust, and hogged wood the type of grate or the use of any grate is comparatively unimportant, whereas the method of introducing fuel to the furnace under control is all important.

A large number of furnaces with flat grates or without grates are giving evaporative results of 6 lb. per pound of wood fuel. With no grates the ashpit is cleaned about once in three months, and it has been said that a layer of ashes about 2 in. deep is found.

Our patented, automatically controlled wood-fuel stokers are operating in connection with furnaces with inclined grates and with similar furnaces with flat grates, and apparently there is not much, if any, difference in evaporative results. A comparative test between flat grates and inclined grates with all other conditions unchanged would be interesting. The Hofft grate is a good grate, and the writer does not wish to be understood in condemning it in any way, but our experience in a great number of cases indicates that changing flat grates to inclined grates would not yield anything like the improvement in evaporative results that the same expenditure would give if applied to increasing the size of the combustion chamber.

[3] Curtis Companies Incorporated, Clinton, Iowa.

[4] President, Allington & Curtis Mfg. Co., Saginaw, Mich.

The difference in expense between a small and a large combustion chamber is not great, as both would have suspended arches, which would cost the same for either type.

The author's Fig. 3 illustrates a low boiler setting with inclined grates, four of which are in use by the M. B. Farrin Lumber Company in Cincinnati. It is true that charred and partly burned fuel was carried out of the stack before the inclined grates were installed, and this was caused by the blast of air from the cyclone which fed the furnaces at that time, but the author fails to state correctly what stopped the partly burned fuel being carried out. This result was secured by installing, simultaneously with the Hofft grates, Allington wood-fuel stokers which automatically deliver the fuel to the grates without any air blast; and in our opinion, if the grates were dropped level, at least as good if not better results would be secured because of the increase in size of the combustion chamber and the greater distance the fuel would drop before striking the grates, thus giving the particles of fuel time to become ignited before landing.

It is not a fact that blocks, sticks, and rubbish cannot be burned in furnaces designed for suspension burning, provided they are supplied with grates.

The refractory walls of a furnace are not injured by erosion of larger particles of fuel which drop part way to the bottom of the furnace and are picked up by the draft and carried back up to the boiler. This is, first, because these particles do not come in contact with the walls and, second, because if they are heavy enough to drop part way to the bottom of the furnace, but are only partly consumed and are picked up by the draft and turbulence of the gases, they are held in suspension and burned in suspension and are not forced against the walls of the furnace, as there the gas velocities are the lowest.

If high furnace temperatures are produced which injure the refractories, it is not indicated that the efficiency of suspension burning should be sacrificed, as a lesser fuel supply will reduce the temperature, but if the highest ratings are to be secured from the boilers, high temperatures must be maintained, and this is true of all furnaces and not confined to furnaces designed for suspension burning.

In suspension burning, whether complete or partial, it is important that the fuel be fed in a steady, open stream so that the particles are separated from each other the instant they enter the furnace. This we accomplish by a comparatively high-speed screw which feeds a steady, continuous stream of small cross-sectional area and does not feed with charges of approximately a cubic foot of refuse per turn of a screw, as stated in the paper. Our present method was adopted and our former paddle-wheel feeder-reel method was abandoned because the feeder reel empties each pocket in a mass to the feeder chute and not in a fine spray as stated.

There are comparatively few woodworking plants, large or of any size, having boiler settings in which the combustion chambers cannot be largely increased at reasonable expense considering the added economies and higher efficiencies to be secured. Of course there are very small plants where there is little efficiency in any department, but oftentimes a considerable enlargement of combustion chamber can be secured merely by lowering the grates and so obtain the semi-suspension combustion results for the wood fuel. An immediate coal saving has been the result.

ARTHUR D. SMITH, JR.[5] In regard to the smoke nuisance, our boiler plant consists of two 235-hp. return-tubular boilers, equipped with Hofft grates and furnaces and Allington-Curtis wood refuse stokers. Since the installation of the furnaces and stokers, we have had no difficulty in complying with the City of Philadelphia smoke ordinances, although prior to their installation we were in constant difficulty with the city authorities. It is our opinion that the even rate of feed of the wood refuse is of paramount importance in eliminating smoke.

As to furnace refractories, we have had some trouble with maintaining the refractory nose tiles in the Hofft furnaces. We find that very high temperatures are formed in these furnaces When operating at 150 per cent rating, we have developed a furnace temperature high enough to clinker a 2800-deg.-fusion-point coal.

Due to the high furnace temperatures developed, it is our experience that unless a coal is used with a sufficiently high fusion point, no end of difficulty will be experienced with the Hofft furnaces and grates. If clinker is formed, it is very difficult to move the rocker arms which operate the pusher grates, and if one is successful in breaking the clinker, a great deal of combustible coal will be carried down with the clinker into the ashpit. For this reason, we have insisted on buying coals with the highest possible fusion point.

We have found, however, that the Hofft furnace will handle coal with a volatile content as high as 35 per cent, without causing objectionable smoke. To be assured of no smoke trouble, we would recommend limiting the volatile content to 25 per cent, although the higher content may be used if extreme care is taken in coking and pushing back the coal. With the higher volatile coal, it has been found helpful to admit quite a little excess air for a few minutes after each firing.

Due to the slanting ashpit, it requires considerable labor to take out the ashes. Under the conditions in our boiler plant, the firemen are not able to handle coal of over 10 per cent ash content.

There is one question in regard to the mechanical hog which the writer would like to raise. Both the knife type and hammer type have been described, but the power requirements of each have not been discussed.

RAYMOND E. CALLER.[6] It is common practice in all power plants to think nothing of spending power enough to pulverize coal, and to pulverize coal in a plant will run all the way from 15 to 25 kw-hr. per ton. To crush coal instead of pulverizing, requires from 3 to 5 kw-hr. per ton.

THOMAS D. PERRY.[7] On the question of the hog that has been brought up, it is not always possible, as we have discovered in our own experience, to exercise choice. For instance, the knife hog will work well on veneer or thinner substances and also on a number of types of wet wastes. When, on the other hand, we come to relatively large blocks or if we run into fairly substantial chunks that may come from one cause or another, we find that a hammer hog is almost essential. On the other hand, the hammer hog will not handle wet veneer. In other words, the choice of hogs is to quite an extent dependent on the type of material that one has to reduce.

We found with a large waste bin in a Hofft apparatus that it is often more efficient to build up a full bin and burn it into the night. We built in our plant a bin calculated to hold enough fuel for three days' firing, and in that way we can largely eliminate the overloading of feed apparatus during the day. In other words, we run this surplus fuel off at night when we are not using other power.

MR. CALLER. How do you get the three days' supply out of that bin?

MR. PERRY. We have never had three days' supply yet. It is calculated to carry three days' supply. We have never yet had any cause of difficulty in being unable to feed from the underside instead of the incoming drop on top. What is the size of the bin referred to by Mr. Puckett, speaking for the author?

[5] Geo. W. Smith Woodworking Co., Philadelphia, Pa.

[6] Allington & Curtis Mfg. Co., New York, N. Y.

[7] New Albany Veneering Co., New Albany, Ind.

N. P. PUCKETT.[8] It was 21 ft. high and held about 21 tons.

MR. CALLER. We have been unable to prevent arching in a bin over 10 ft. high.

MR. PUCKETT. We have carried adzer shavings, which are very much like a straw pile, as high as 20 ft., without any difficulty.

M. H. TEAZE.[9] Several years ago we were employed as engineers out on the Pacific Coast, and Mr. Hofft gave us a proposal of one of his grates which was turned down principally because it was felt that it was not long enough. We finally installed a grate which was designed for burning coal, and we made that furnace 12 ft. long. We used preheated air for the firing. Practically all the combustion was on 6 ft. of grade surface. The grates function perfectly and gave an excellent fire, but for some reason there was a clinker in the perforations, which are similar to those that Mr. Hofft uses. Those clinkers are so hard that they could not get the stuff broken out. We finally decided to abandon those grates and have adopted a step grate which is somewhat similar to the upper Hofft grate. The principal purpose of this is to enable the operators to get in the furnace over the week-end and break up the slabs.

MR. BROOKS. One often wonders whether refractory problems are entirely a question of temperature or whether they may not be a question of the chemical constituents of the fuel that we are burning, possibly forming low waste with the refractories themselves and thereby producing the deleterious effects that give the trouble. In one installation of the Ford Motor Company in northern Michigan that question came up, so that it is likely that many have had similar problems.

MR. CALLER. It is found in Detroit plants that when they go beyond a furnace rating of about 175 per cent, sufficient heat is generated from the combustion, so that the very chemica combination that is referred to takes place and starts to work on the refractories. Running wood waste at a high rating necessarily makes high temperatures. That has been so serious in the furnace upkeep that it is a hard rule with some of our customers that they will not run wood over 175 per cent.

MR. BROOKS. In the coal-burning line, we are out of the habit of speaking in terms of per cent of rating. Today we think in terms of boiler horsepower per cubic foot. I wonder what this 175 per cent rating means. I wonder if any one ever has isolated any of the chemical elements that are so harmful to the refractories. What chemical element is it that is released at these high temperatures that produces that effect?

MR. CALLER. I have no information to go on record with, but I believe that the chemists and engineers from the General Motors could very well reply to that question.

MR. BROOKS. The matter of silica alone does not seem to enter into it, because silica itself is one of the best refractories. There must be some combination with silica. There are certain of the siliceous metallic combinations which have very low ash fusion; ferrous silica will run down to 600 or 700 deg., so that probably there must be some combination of the silica with some metallic form producing a fusion.

MR. SMITH. Very often a part of our work is made from the so-called fireproofed wood, which has been treated by impregnation with certain salts. We have found that where even a small percentage of the shavings or refuse is from fireproofed wood, the fusion of the ash within the furnaces was very greatly increased. The writer has seen our furnaces with the ash fused to the refractory walls until it projected out into the furnaces 12 in. or more.

It has been stated that the knife hog is not suitable for large blocks or heavy lumber. We have a knife hog in our plant which is now successfully hogging materials up to 6 in. thick, as well as the thin veneers and lighter woods. We are also using it for reducing all of our crating materials, including nails and light strap iron. Unintentionally, some heavier metals have got into the hog and left their mark on the knife, but our hog operates on an average of three hours per day and the knives are changed only once in every two months. From this, it does seem that the knife hog is capable of handling the heavier material and also crating materials without much serious damage.

MR. PERRY. One fact comes home from the discussions, and that is the lack of thorough and proved information on the value of wood waste as a fuel. With that also, we must consider that the utilization of this waste is not in all cases a primary power-production problem. It often becomes a problem of disposal of a rather miscellaneous type of waste accumulating from a variety of woodworking operations. In our factory we have a large amount of glue, wrapping paper, and various other things that accumulate in a factory, and while Mr. Smith has made an interesting plea for the knife hog, I still continue to feel that where there is a considerable amount of metal coming in with the waste, one cannot sort out for the hammer knife as the other type. In the hammer hogs, they generally have a metal pocket which, by centrifugal force, throws off the heavier particles. I imagine that two-thirds of the metal will be segregated and thrown off.

MR. PUCKETT. With regard to the inability to operate the pushers, probably the low-fusion ash and the treated wood have brought about those conditions.

AUTHOR'S CLOSURE

In burning coal and wood in the same furnace the best results are obtained by firing them separately, although this is not always necessary. However, it is not advisable to burn dry wood and coal, with a low-fusing-point ash, in the same furnace at the same time; for the burning of the dry wood, especially at high ratings, will bring up the furnace temperature to a point where it will fuse the ash of the low-fusing-point ash coal. It is even difficult to burn this low-fusing-point ash coal at high ratings, alone, on account of the melting of the ash and heavy clinkers. These difficulties of course are not experienced with coal having a higher fusing point to its ash.

The stoker Mr. Teaze refers to as having air spaces similar to the one described in the paper probably was of the shaking-grate type with grates 6 or 8 in. by 3 or 4 ft., extending crosswise of the furnace. This grate would have a tendency to slag over the air spaces. That is the reason for the design of the grate with the pushers 3 in. by 12 in. operating between stationary grates like a rake. The operation of a row of these pushers between the grates cracks off the sheet of sand slag that sometimes forms in a furnace burning refuse from logs having considerable sand in the bark or that are delivered by salt water. This glassy slag would also come in plants where there is a considerable amount of sander dust. This slag is rather brittle and would be removed with the raking of the pushers between the grates.

With regard to arching of fuel in the bins, the screw-bottom bin described was developed to overcome serious trouble caused by the arching of fuel in the bin. This fuel was part dry sawdust and shavings and part wet veneer strips that were not finely hogged, but came in rather large pieces. The ordinary agitators would not break up this fuel. After a lot of experiments with this fuel, this screw-bottom bin was developed, and there never has been any arching since, and even more difficult adzer shavings are being handled with the same type of machine.

The author limited this paper to his personal experience in this type of equipment and did not attempt to describe all types of wood-handling equipment and refuse-burning furnaces, as these designs have been ably discussed in many other papers.

WDI-53-2

Longitudinal Shrinkage of Wood

By ARTHUR KOEHLER,[1] MADISON, WIS.

Longitudinal shrinkage of wood ordinarily is so small as to be considered negligible, and no allowance is made for it for most uses. There are uses, however, for which even the small longitudinal shrinkage of normal wood is an important factor, and others in which the shrinkage along the grain of abnormal wood is so large as to be a serious handicap. This paper gives information on the shrinkage of wood along the grain about which very little has been published.

SHRINKAGE along the grain of wood may be objectionable under the following conditions:

1 When it causes undue shortening in length, particularly in posts, so as to throw the adjoining members into serious disalignment. As a rule, no allowance is made for longitudinal shrinkage as is usually done for transverse shrinkage, and consequently when it does occur to an appreciable degree it often causes trouble.

2 When it causes exceptionally wide opening of butt joints.

3 When it causes bowing or cross breaks in pieces which shrink unevenly longitudinally.

4 When it weakens wood in longitudinal shear on account of stresses set up as a result of variations in shrinkage potential of different layers in timber or other members.

5 When it causes slivers to loosen and raise up from the face of a board.

Variations in Shrinkage

The data here presented are the result of an initial investigation by the Forest Products Laboratory into causes for the variation in the shrinkage of wood. There are large variations in the shrinkages of the different species of wood, in the individual pieces of the same species, and in different directions on the same piece. These variations can be accounted for primarily by differences in the cellular structure.

The longitudinal shrinkage of wood normally ranges from 0.1 to 0.2 of 1 per cent. Unless otherwise stated all shrinkage values given in this paper represent the total shrinkage from the green or soaked to the oven-dry condition, that is, a condition of zero moisture content. In drying to an average air-dry condition of about 12 per cent, the shrinkage would be about one-half as much.

Cases have been observed in which the shrinkage along the grain was abnormally large. The greatest longitudinal shrinkage so far recorded at the Forest Products Laboratory is 5.78 per cent in wood from the lower side of a limb of western yellow pine. This is more than the average transverse shrinkage for the species. It is equivalent to a shortening of 11.1 in. in a 16-ft. board. On the other extreme, slight elongation has been observed in certain woods in drying.

Fig. 1 gives shrinkage values for 34 different types of wood at three different percentages of moisture content; namely, about 12 per cent, about 7 per cent, and at 0 per cent. Shrinkage is assumed to have begun at a moisture content of 24 per cent, which is taken as an average fiber-saturation point. Different types of wood were selected so as to give as wide a variation in shrinkage as possible; consequently the values given in Fig. 1 are not intended to represent averages for any species.

Conditions Under Which Excessive Longitudinal Shrinkages Occur

No sharp limits can be set above which longitudinal shrinkage in wood may be called excessive. A total uniform shrinkage potential of 0.3 of 1 per cent, however, is near the maximum permissible for most uses. It would cause a shortening of 0.58 in. in a 16-ft. board if oven dried. For numerous uses, 0.2 of 1 per cent would be the maximum permissible. Fortunately most wood falls below these limits. If the longitudinal shrinkage is not uniform from side to side, an even smaller shrinkage may be objectionable on account of the bowing which it may produce. Shrinkage beyond these limits has been found to occur in the following types of wood:

1 *Compression Wood.* Compression wood is a hard, heavy, brittle type of wood formed on the lower side of branches and leaning trunks of coniferous trees. It is characterized by rather wide annual rings containing wide summerwood that is not so dark and hornlike as in normal wood. Fig. 2 shows a cross section of a spruce log in which compression wood is well developed. Within any annual ring compression wood is confined to one side of the pith, that is, it does not extend continuously around the trunk. It may be continuous from the pith to the bark, or it may occur in intermittent layers. In some annual rings it may be in one direction from the pith and in others in a different direction. Therefore, it frequently happens that boards or dimension stock have streaks of compression wood in them. Compression wood, having a greater tendency to shrink longitudinally than normal wood, usually causes a bowing of lumber in which it is unevenly distributed. (See Fig. 3.) Occasionally streaks of compression wood that adjoin normal wood will pull themselves apart so as to form cracks across the grain.

Compression wood is a source of considerable trouble in the drying and use of softwood lumber, principally on account of the bowing which it produces. Sometimes the direct shortening causes trouble. For example, butt joints in redwood and cypress siding occasionally open up on account of the longitudinal shrinkage of compression wood in the siding. If the siding is well-dried before it is nailed down, however, there will be no occasion for any further shrinkage to take place. No sharp line of distinction can be drawn between compresion wood and normal wood the two grade into each other imperceptably. Therefore, no fixed shrinkage value can be ascribed to compression wood. The maximum longitudinal shrinkage so far found in compression wood has already been given for wood from a limb of western yellow pine. The maximum shrinkage so far determined for compression wood from a tree trunk is 5.42 per cent in a southern

---

Mr. Koehler has been engaged in the study of the cellular structure of wood for identification purposes and to explain the variations in the behavior of wood since 1911.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

yellow pine. More often the shrinkage of compression wood is less than 1 per cent but over 0.3 of 1 per cent.

2 *Abnormally Light-Weight Wood.* Wood below the average weight for a species shrinks more along the grain than heavier wood of the same species. This is shown in Fig. 1 for high- and low-density wood of longleaf pine (1 and 2), tupelo gum (22 and 23), ash (25 and 26), and for red oak of low density which shrunk over 0.8 of 1 per cent. Fig. 4, which shows the shrinkage of redwood of different specific gravities, clearly indicates a general trend toward a reduction in shrinkage with an increase in specific gravity. All of the specimens represented in Fig. 4 above the 0.400 per cent line and about one-half of those between the 0.300 and 0.400 per cent lines consisted of compression wood. With this fact in mind, the downward trend of the remaining points which represented normal wood almost entirely, is more apparent. Balsa, on the other hand, which normally is a very light wood, did not shrink so much as most of the other specimens

3 *Springwood.* In many species of wood each annual growth layer is differentiated into an inner, softer layer of low density, the springwood, and an outer, harder layer of high density wood, the summerwood. The springwood invariably shrinks more along the grain than the summerwood. This is easily demonstrated by whittling out a piece of wood only one annual ring in thickness and observing the way it bows lengthwise of the grain as it dries.

The greater longitudinal shrinkage of springwood as compared with summerwood is shown in Fig. 1 for loblolly pine (3 and 4), southern yellow pine (5 and 6), abnormal southern yellow pine (7 and 8), Douglas fir (10 and 11), and redwood (13 and 14). Fig. 4 shows that the specimens of redwood of lowest specific gravity, which consisted entirely of springwood, shrank considerably, whereas those of highest specific gravity, which consisted entirely of summerwood, shrank very little. Figs. 1 and 4 show that some pieces even elongated in drying. Such elongated pieces invariably consisted of summerwood only.

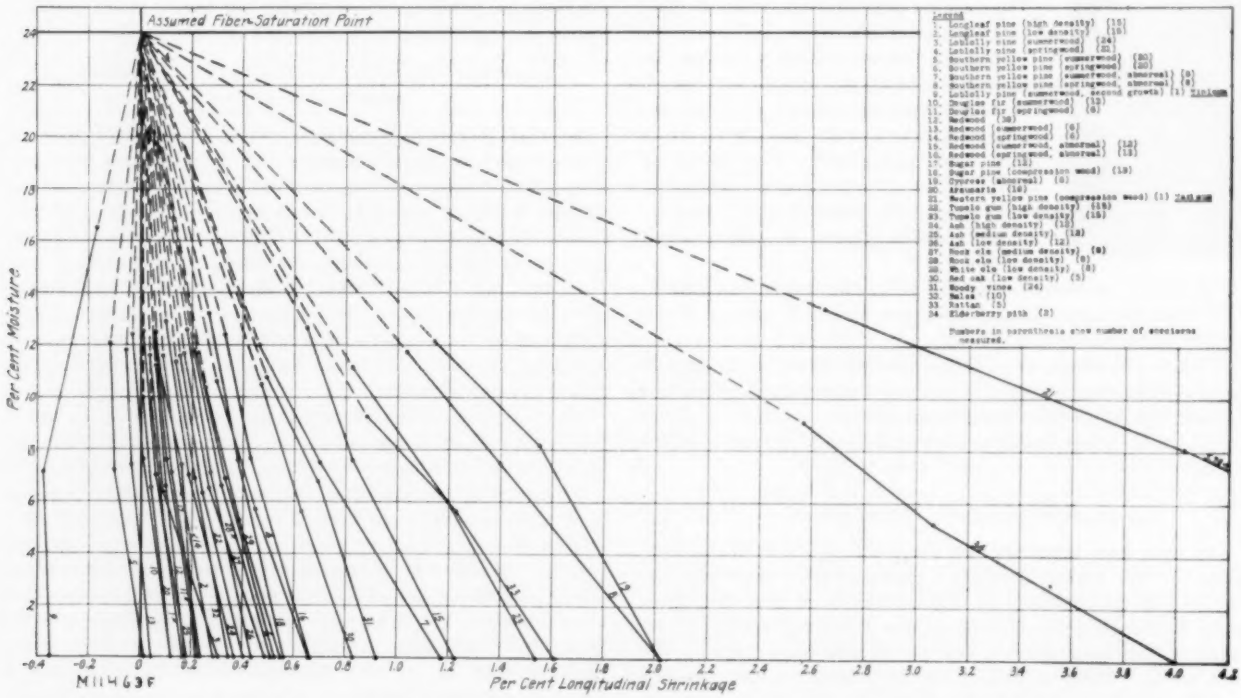

FIG. 1 LONGITUDINAL SHRINKAGE OF VARIOUS TYPES OF WOOD AT THREE DIFFERENT PERCENTAGES OF MOISTURE CONTENT

that were light in weight. (See Fig. 1.) It is only wood which is considerably below the average weight for the species that shrinks excessively along the grain.

This peculiar relationship is due to the fact that in normal-weight wood most of the fibrous cells, or wood fibers, are constructed so that they do not shorten much in drying, and since the wood fibers predominate, as a rule, they control the shrinkage of wood as a whole. In abnormally light-weight wood, however, either the wood fibers have a different type of structure or they are so scarce that the other kinds of cells predominate, particularly those that make up the pores, which have a high shrinkage potential. The relationship between longitudinal shrinkage and density is just the opposite of what it is for transverse shrinkage and density; that is, in general the heavier the wood the more it shrinks across the grain. The relationship between density and shrinkage, whether longitudinal or transverse, is caused by the fact that the woods of low and high densities have different cellular structures, and not by the fact that there is a difference in the amount of wood substance present.

Within a piece of wood several annual rings in width, the springwood, of course, cannot shrink more than the summerwood since the two are so closely and alternately bound together. The difference in shrinkage potential, however, undoubtedly sets up stresses which may possibly produce shear failures either directly or when supplemented by stresses due to external loads.

In flat-grain lumber the greater longitudinal shrinkage of springwood frequently causes slivers to loosen and curve away from the surface, especially on the pith side. This condition frequently is exasperating in flat-grain flooring. It can be largely avoided by dressing pattern stock so that the face side is on the bark side of the piece. In that event, the summerwood of each annual ring is toward the outside, and consequently the tendency of the annual rings to curve up is eliminated.

Rotary veneer occasionally happens to be cut so as to be one annual ring in thickness. Under such circumstances, any difference in shrinkage potential of springwood and summerwood causes local curvatures.

4 *Wood Near the Pith of the Tree.* Boards and planks of the

southern and western yellow pines, and occasionally other species, which happen to be sawed lengthwise through the pith, frequently show cross breaks extending for a short distance at right angles to the pith. (See Fig. 5.) Such breaks are due to the greater longitudinal shrinkage of the wood near the pith. For the same reason, narrow strips cut out so that the pith runs along one edge will bow as they dry.

On the other hand, it has been reported that the wood on the bark side of some hardwood shrinks more than the wood away from the bark, and thereby causes bowing. The explanation probably is that the density of the wood in such pieces decreased toward the outside of the tree, as frequently is the case, and as previously stated, low density wood shrinks more longitudinally than that of high density.

5 *Wood in Very Fast Growing Conifers.* In loblolly pine and red-

FIG. 2 CROSS SECTION OF SPRUCE LOG SHOWING COMPRESSION WOOD—THE DARK, WIDE-RINGED PORTION

wood relatively high longitudinal shrinkage has been found in second-growth trees with very wide annual rings containing summerwood which is not so dark and hard as in normal wood. Such wood resembles compression wood in some respects, but differs from it in extending entirely around the tree trunk and in some microscopic features. Wood of this type was found mostly in the butt portion of the trunk. Probably it also occurs in other species than the ones mentioned.

6 *Cross-grained Wood.* In any piece of wood in which the grain does not run parallel with the long axis, there may be excessive apparent longitudinal shrinkage due to a transverse shrinkage component being effective along the length of the piece. If the grain ran at an angle of 45 deg. across a board it would shrink as much on a percentage basis along its length as along its width. Wood with spiral, diagonal, interlocked, wavy, or curly grain may have excessive apparent longitudinal shrinkage on account of the presence of cross grain. A knot along one edge of a narrow strip will cause bowing of the strip due to the cross grain which it produces.

7 *Long Pieces of Wood.* Although a long piece of wood should not shrink any more than a short one of the same kind on a percentage basis, the actual shrinkage is proportional to the length. The greatest shortening effect therefore, would be expected in long boards, planks, timbers, or the like. The present tendency toward increased use of short lengths will, therefore, help to break up the longitudinal shrinkage into smaller units, which will be particularly advantageous in keeping down the width of openings in butt joints in siding and flooring.

RELATION OF LONGITUDINAL SHRINKAGE TO MOISTURE CONTENT

No attempt has been made by the author to determine the moisture content at which wood begins to shrink longitudinally in drying. It is hardly conceivable that it would be any different from that at which transverse shrinkage occurs; namely, the fiber-saturation point, which averages about 24 per cent moisture.

FIG. 3 BOWING OF LOBLOLLY PINE AS A RESULT OF EXCESSIVE SHRINKAGE OF COMPRESSION WOOD (DARKER PORTION) ADJACENT TO NORMAL WOOD

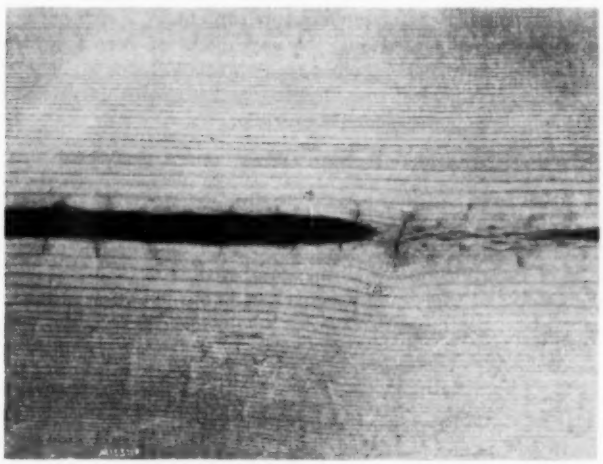

FIG. 5 CROSS BREAKS IN WESTERN YELLOW PINE DUE TO GREATER LONGITUDINAL SHRINKAGE OF WOOD NEAR PITH

Although most of the points representing shrinkage for different percentages of moisture content in Fig. 1 are not in a straight line or characteristic type of curve for each kind of wood, they agree fairly well in pointing to about 24 per cent as the moisture content at which shrinkage began.

Among the specimens of low shrinkage there is a slight tendency to curvature in the shrinkage lines, indicating that the shrinkage rate increases as the moisture content decreases. Some of the specimens showed no shrinkage or even elongated in the first and second stages of drying, but when all moisture was removed they were shorter than when wet.

Longitudinal shrinkage, like transverse shrinkage, depends on the change in moisture content below the fiber-saturation point. If wood is dried so that it will not change a great deal in moisture

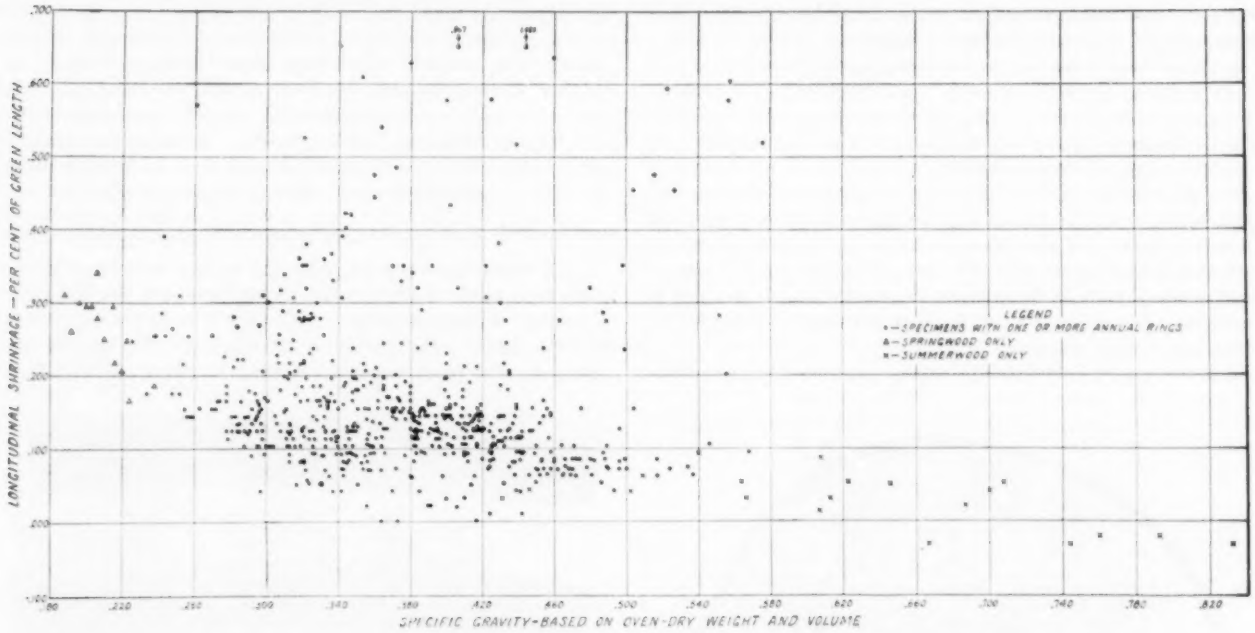

FIG. 4 RELATION OF LONGITUDINAL SHRINKAGE OF REDWOOD TO ITS SPECIFIC GRAVITY

content when used, then it will not shrink appreciably along the grain, no matter how abnormal its shrinkage potential may be. For uses in which the wood becomes alternately wet and dry, previous drying, of course, does not prevent subsequent changes in dimensions with changes in moisture content.

As previously pointed out, the uses discussed here in which longitudinal shrinkage becomes an important factor are far in the minority; for most uses the longitudinal shrinkage of wood is so small as to be considered negligible.

FUTURE WORK

Further investigations are under way at the Forest Products Laboratory to determine how the cellular structure of wood affects its shrinkage. It is believed that information on the cause of variations in the shrinkage of wood will be of value in diagnosing and explaining peculiarities in the behavior of wood, and in learning how to recognize wood which has an exceptionally large shrinkage potential, so that difficulties that might result therefrom may be guarded against. It is also believed that an understanding of the mechansim of wood shrinkage will be of value in developing treatments for reducing the shrinking and swelling of wood in use. It has already been discovered that the pitch of the spirally wound cellulose fibrils of which the cell wall is composed is one of the controlling elements in longitudinal shrinkage, the less the pitch the greater the shrinkage in the length of the cell. Theoretically, the reverse should hold for transverse shrinkage, and it was found to do so in many cases. For example, compression wood shrinks less than normal wood, and springwood shrinks less than summerwood across the grain. Evidently other factors also come into play in transverse shrinkage, the importance of which should be determined by the further investigations now under way at the Forest Products Laboratory.

Curved and Bent Plywood

By THOMAS D. PERRY,[1] NEW ALBANY, IND.

Curved surfaces on solid wood reveal unattractive wood grain and are seriously lacking in strength and rigidity. The veneering of curved surfaces on solid wood is an ancient art. A description of the curving of plywood for modern designs is timely, since curved surfaces are passing through a period of style popularity. The paper gives a concise description of the building of curved plywood, as well as of the bending of plywood by processes just emerging from the experimental stage. Suggestions are given for the necessary tolerances in size and shape, the trimming and sanding of the curved shapes, and the accessory equipment required therefor. Attention is called to the fact that, pound for pound, wood is the strongest material known; hence curved plywood has an opportunity to become an industrial product with wide applications and substantial economic value.

FROM time to time curved veneered surfaces have been conspicuous in wood-product designs, and just at present they are unusually popular. There are several approved methods of producing such curved veneer and plywood; methods that depend on the quantity, on the complexity and abruptness of the curve, and on the strength and rigidity required. The three best developed processes are as follows:

(1) Curved veneering on solid lumber
(2) Building curved plywood cold (with rigid male and female dies) during gluing
(3) Bending plywood with heat after gluing.

Historic Methods. Surviving examples of early artistic veneering consist almost wholly of single-ply veneer glued by hand, practically the first of the aforementioned processes, on flat or curved foundations of an inert and stable wood like pine or poplar. This veneer was applied with what is known as a veneering hammer (see Fig. 1), which really was a hand pressing tool drawn or pushed over the surface of freshly glued veneer to produce complete adhesion and to squeeze out the glue, while making the close and tight surface joints required in high-grade veneering. Such veneered work has endured for hundreds of years, and has not only been proved durable by time, but also has been judged genuinely artistic by leading designers of past and present wood products.

Mechanical Limitations. Given plenty of time and skilled artisanship, it is possible to attach veneer to almost any curved surface. Even long circular columns and complicated re-entrant curves can be veneered. As a practical manufacturing problem for quantity production, however, only such curves can be successfully and economically veneered as can be formed under platen presses with vertical pressure. There is a definite limit to the curved segmental angles that can be glued effectively. Reference to the pressure diagram in Fig. 2 will indicate that, with a direct pressure A of 75 to 100 lb. per sq. in., a 90-deg. segment will have approximately two-thirds of this pressure at its extremities, while one of 120 deg. will have only one-half of this pressure, as at C. It is possible to veneer the latter successfully, and it will include sufficiently more than a quadrant to produce grooved and well-fitted corners. It is obvious that a segment of 180 deg. would have no vertical pressure component, and its only pressure would be derived from the snugness of the forms. This limit of 120-deg. segmental angle applies to both simple and compound curved surfaces. Bending machines, under the third process, may raise this limit to 240 deg.

No definite size limits can be stated as conditions vary so widely. In general, curves more than 2 ft. wide (around the curve) and more than 2 ft. long (parallel to the cylindrical axis) are quite exceptional and are rarely required on a quantity-production basis. Hence their methods of manufacture have little practical background. Grand-piano rims are invariably made of curved plywood and are an exception to this classification. Probably 90 per cent of curved plywood falls within the foregoing size limits, and the methods outlined will be particularly applicable to this majority portion.

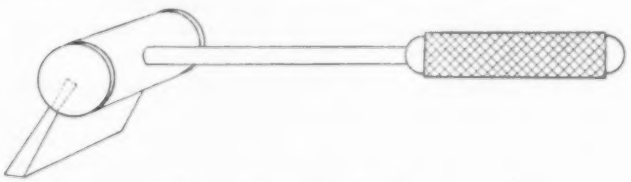

FIG. 1 VENEERING HAMMER
(Used for pressing veneer to base and squeezing out surplus glue.)

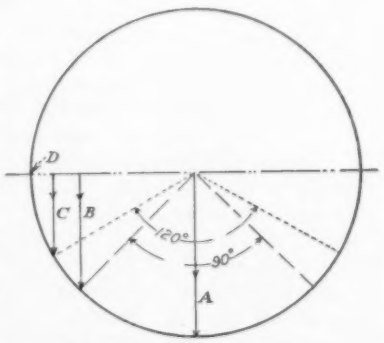

FIG. 2 PRESSURE DIAGRAM
(Indicating distribution of vertical pressure for various sized segments.)

Glue Requirements. The principal wood adhesives of commerce are each adapted to certain kinds of curved work, but none of them is universally applicable to all kinds of bent and curved plywood.

Successful plywood glues for use in curved products must hold their fluidity well—i.e., must not evaporate too rapidly in bulk or while spread, waiting for pressure; at the same time they must set quickly under pressure, so that gluing equipment can be used repeatedly during the daily working schedules. Ordinarily such quick-setting glues are low-moisture-content

[1] Works Manager and Engineer, New Albany Veneering Company, New Albany, Ind. Mem. A.S.M.E. Mr. Perry has devoted many years to engineering in the wood-industries field and has served as vice-president and manager of the Grand Rapids Veneer Works and as consulting engineer with Bigelow, Kent, Willard & Company, of Boston, Mass. He is chairman of the Wood Industries Division of the A.S.M.E., and the author of many articles dealing with lumber-handling equipment, woodwork, and engineering practice with veneer, plywood, and solid wood.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

brands, requiring from 66 to 75 per cent of the normal amount of mixing water. They are usually rather above average quality and price. Ordinary glues or cheap glues are hazardous on curved and bent work.

A satisfactory working schedule is three hours under pressure or about four hours between successive gluings. This permits from two to six charges, according to the length of the working day. Where 1000 units are required daily, and the forms cost $10 per set, the charges per day become an important economic item.

Animal glue was the original standard for veneer work, but

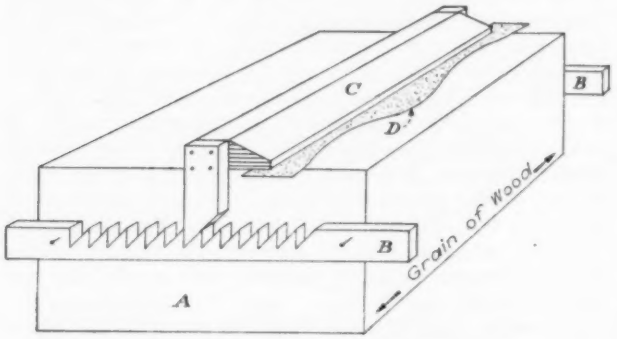

FIG. 3 MARKING TEMPLET, WITH METAL EDGE
(*A*, block of laminated wood; *B–B*, racks for spacing; *C*, templet holder, of plywood; *D*, metal templet.)

is of such a cost that its principal application is to the curved tasks where skilled labor is required and volume is very moderate. It is an excellent manual glue, but after setting it is neither moisture proof, nor does it resist the action of heat above 140 deg. fahr. It is the only one of the glues mentioned that requires heated wood and 80 deg. fahr. workroom temperatures for its successful application.

Vegetable glue is made from a starch base, usually of casava or tapioca flour, and is especially adapted to a large volume of standardized production. It is moderate in price, and when properly blended can be removed from pressure in a minimum of two and one-half hours, although three hours is safer. Due to its heavy, tacky qualities, it must be mixed and spread mechanically. It has no material advantages over animal glue in either moisture or heat resistance. Room and product temperature may be normal workroom conditions.

Casein glue is a milk product that can be mixed and applied cold. It has water- and heat-resistant qualities and is suitable to use in dry-bending operation with a short exposure to temperatures around 200 deg. Its water-resistant qualities depend on lime content, but high water resistance requires a large lime admixture and it becomes very brittle. It must be machine-mixed, but can be spread manually or mechanically. The best grade for dry bending is a low lime content, and the plywood should be bent within 24 to 48 hours from laying. Casein costs are about midway between animal and vegetable glues.

Blood-albumin glue is a packing-house product and consists chiefly of dried blood. Its use is fully described under the wet-bending process later in this paper.

CURVED VENEERING ON SOLID LUMBER

Fundamental Principles. The fundamental principles of success in this process of curved veneering are three: first, the selection of wood of such quality as will tenaciously hold glue and serve as a suitable foundation for the thin, fragile sheets of pliable veneer to be attached thereto; second, the preparation of thoroughly stable and inert bases of suitable curved shapes with sufficient strength to carry the strains of hard usage in a piece of furniture; third, gluing the veneer to such carefully selected and designed bases with proper regard to figure, joints, and freedom from surface breaks.

In the past such work was ordinarily glued with animal glue, but modern practice approves several other more recently developed adhesives.

Preparing the Block. The curved bases on which the veneer is to be glued are most advantageously made from large blocks of wood, band sawn to the desired shape. These blocks of wood are preferably laminated out of 4/4 in. stock and must be thoroughly kiln-dried, as well as square on every face, in order that the marking and saw cuts may be free from irregularity and imperfection. The grain of laminations is usually parallel without cross-banding, since the cross-veneer increases the difficulty of sawing, but does prevent warping. Such blocks must be of a convenient size for ready handling on the band-saw table and must be of such dimensions that the band saw will readily cut without binding, running, or whipping in the cut.

It is possible to make successful band-saw cuts as deep as 22 in., but accuracy of form and speed of cutting are sacrificed in such thick blocks. It is much better practice to confine the thickness of such blocks to a range between 6 and 12 in., permitting more rapid sawing and eliminating to a large degree the tendency toward irregularity between the desired curve at the bottom and top of the block.

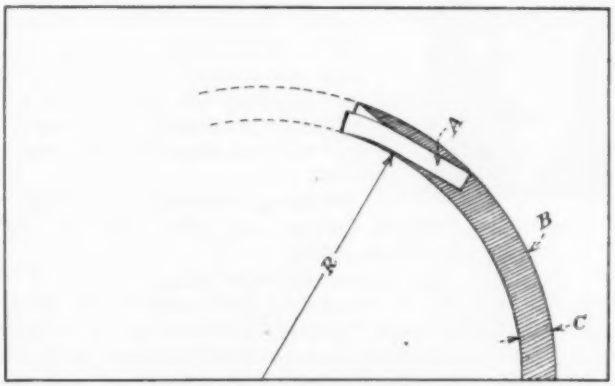

FIG. 4 LIMITING CONDITIONS FOR BAND SAWING
(*A*, section of band-saw blade; *B*, saw cut from which kerf has been removed; *C*, must equal veneer in thickness; *R*, radius of saw cut, inside.)

Several woods are in current use for blocks of this kind, and each has its special qualities. White pine is ideal in that it works easily, glues excellently, and retains its shape. It is, however, decidedly costly, as well as rather soft and easily dented. Yellow poplar is not quite as stable as pine, but is denser and rather harder. Sound wormy chestnut makes an excellent block and is, from the standpoint of economy, stability, and gluing qualities, one of the best blocks available. It is largely used by discriminating manufacturers of curved veneered parts.

Templets for Marking. If only a very few pieces are to be produced, it is of course possible to scribe the curve directly on the block with drawing instruments or to make wooden templets for a limited number. Quantity production demands standardization of shape, and a method of utilizing metal templets is shown in Fig. 3, in which two exactly similar racks *B-B* are nailed to either end of the block and serve as spacing guides to insure uniformity of thickness in the sawn curved bases.

For moderate production quantities the metal templet *D* can be made from zinc, brass, or aluminum and sawn to shape on the woodworking band saws. For large quantities and unusual

accuracy this templet should be made of steel. It is obvious that great care must be exercised in making this metal templet, as it must be true to curve, reversible, and free from irregularity.

It is recommended that the templet holder *C* be made of multiple plywood so that its shape may not be seriously altered by climatic conditions.

Sawing the Curves. There are a number of sturdy makes of band-sawing machines that are rigidly built, easily adjusted, and conveniently operated. The best types have electric motors built into saw frames and are equipped with ball bearings.

The problem of selecting a suitable band-saw blade is subject

TABLE 1[1] STANDARD SAW SIZES

Width of saw, in.	Points to inch	Standard Specifications: Thickness, Inch	Thickness, Gages	Minimum radius[2] to be cut, in.
1/8	8	0.028 or 0.025	22 or 23	3/8
5/32	7	0.032 or 0.028	21 or 22	1/2
1/4	6	0.032 or 0.028	21 or 22	3/4
5/16	5 1/2	0.032 or 0.028	21 or 22	1 1/2
1/2	5	0.032 or 0.028	21 or 22	2 1/4
5/8	4 1/2	0.032 or 0.028	21 or 22	3
3/4	4	0.035 or 0.032	20 or 21	4 1/2
7/8	4	0.035 or 0.032	20 or 21	6
1	3 1/2	0.035 or 0.032	20 or 21	8
1 1/4	3 1/2	0.042 or 0.035	19 or 20	12
1 1/2	3	0.042 or 0.035	19 or 20	20

[1] From Disston's Tool Manual (1927).
[2] In ordinary construction there are few exterior curves less than 1 1/2 in. in radius or few interior curves less than 3/4 in.

to a number of considerations. An exaggerated example of the limiting conditions is shown in Fig. 4, in which the set of the saw teeth is clearly illustrated. The saw teeth must be set to produce not only a reasonably smooth surface, but to also properly clear and relieve the heel of the cut of the saw in a cut of the radius required. Standard saw sizes are indicated in Table 1, published in Disston's Tool Manual (1927). These specifications, however, particularly apply to band sawing ordinary 4/4 in. to 8/4 in. lumber. On thicker blocks it will be necessary to reduce the points per inch

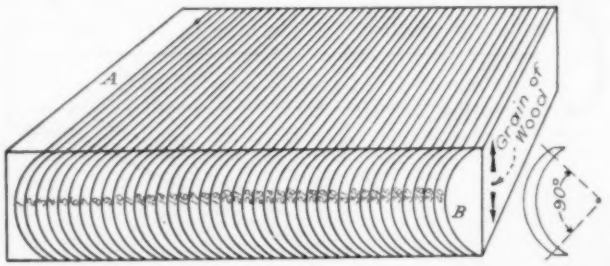

FIG. 5 BLOCK SAWN INTO SIMPLE CURVES
(Showing the sawn segments numbered and laid together in original sequence. *A*, top segment, or male form; *B*, bottom segment, or female form.)

to provide additional sawdust-removal capacity. The width of the saw cut is determined by several important factors, as follows:

(*a*) Gage or thickness of the saw
(*b*) Set of the saw teeth
(*c*) Clearance of the heel of the saw
(*d*) Thickness of veneer to be applied.

The ideal amount of lumber removed in saw kerf should be equal to the thickness of the veneer to be inserted and glued to the sawn surfaces. The width of the saw blade should be as great as possible for strength purposes with due regard to desired radius and necessary width of the cut. The gage of the saw depends partly on the size of wheel used, i.e., thinner saws on smaller wheels.

Authorities vary as to the proper lineal cutting speed of the band saw, but the best authorities recommend from 3000 to 5000 lin. ft. per min. An adequate range of speeds, wheel sizes, and revolutions per minute are given in Table 2.

TABLE 2 OPERATING SPEED OF BAND SAWS

Lineal speed of saw, ft. per min.	Diameter of wheel in inches: 20	24	30	36	42
3000	573[1]	477[1]	382	318	273
3250	621	517	414	345	296
3500	668	557	446[1]	371	318
3750	716	597	477	398	341
4000	764	637	509	424[1]	364
4250	812	676	541	451	387

[1] Recommended speed for wheel (Disston's Tool Manual, 1927).

Formula:

$$\text{R.p.m.} = \frac{\text{Lineal speed}}{(D + 12) \times \pi} = \frac{\text{Lineal speed}}{\frac{D \times \pi}{12}} = \frac{\text{Lineal speed}}{0.262 \times D}$$

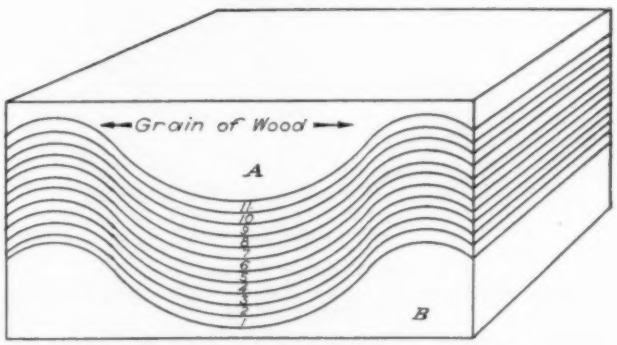

FIG. 6 BLOCK SAWN INTO COMPOUND CURVES
(Sawn sections numbered and laid together in original sequence. *A*, top segment; *B*, bottom segment.)

One manufacturer, making a large volume of sawn curved shapes, has adopted as most satisfactory 620 r.p.m. on a 36-in. band saw, using a 3/8 in. wide, 3-point, No. 19 or No. 20 gage band saw. This gives a saw travel of approximately 5800 lin. ft. per min., indicating that the recommendations in Table 2 are quite conservative.

Laminated lumber blocks, band sawn to simple and compound curves, are shown in Figs. 5 and 6. It is to be noted that when the simple band-sawn curves are nested, the thickness at the center will be slightly greater than at the edge, due to the crescent shape, resulting from the moving center and fixed radius. It is therefore customary to select and use the desired radius for either the inside or the outside of the curved pieces, whichever requires accuracy, and to allow sufficient thickness at the thinnest point. Manufacturing conditions may vary these requirements in certain instances. The same variable thickness occurs in a compound-curved block as a result of the lack of concentricity in the circles. This variable thickness cannot entirely be avoided, but it is seldom a detriment under actual working conditions, as one surface can always be made true and uniform.

The off-bearer at the band saw should be equipped with an efficient hand brush so that all sawdust may be brushed off each successive segment as sawn and the saw table be kept free from any sawdust that might cause tilting of the block during sawing.

Obviously the limiting width along the curve is the depth of the saw cut or about 22 in. If curves of larger dimensions are needed, simple curves may be made on a lathe, but compound curves are exceedingly difficult. Usually such compound curves are made all plywood (rather than veneered on solid lumber), as described under the second process.

Applying the Veneer. In applying the veneer to these sawn

curved shapes, the top and bottom segments (*A* and *B*, Figs. 4 and 5) are used as forms, the veneer being designed to occupy the space between the segments from which the saw kerf has been removed. If it is desired to put $^1/_{28}$ in. face and back on a segment, it will be necessary to use a saw kerf removal of $^2/_{28}$ in., or $^1/_{14}$ in. There are instances, also, where the strain demands a crossband, in which case the thickness of the saw kerf must be increased to permit the insertion of one or two crossbands. More often, however, the segment has sufficient strength for all structural requirements, and frequently sufficient resistance for the strain occurring in the gluing of the veneer to one side of the segment, to permit the use of a single ply of veneer on the face of the segment and none on the back. In such instances the saw kerf need only be $^1/_{28}$ in., although usually somewhat greater in practice.

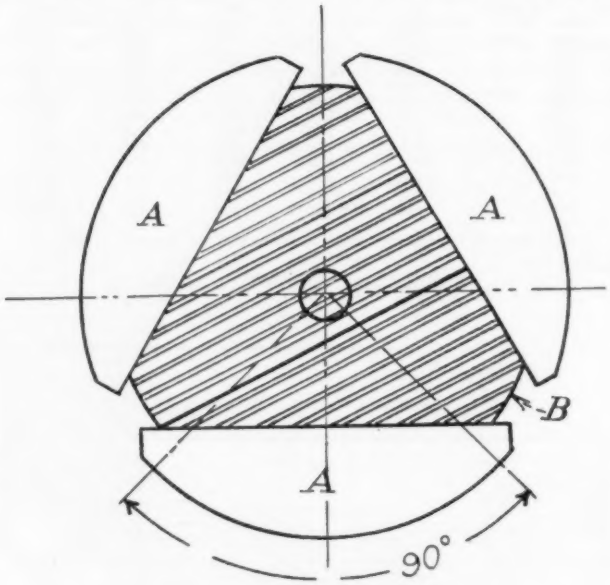

FIG. 7 CIRCULAR SEGMENTS
(Another process of producing circular segments, *A*, *A*, *A*, using a lathe and triangular arbor, *B*.)

The sheets of veneer are usually glued with a mechanical spreader and the wet glued faces placed against the segment, followed by a piece of oil paper and another segment; this is two-ply construction, the base and one thickness of veneer. If a face and back veneer are used, two sheets of veneer would be inserted with unglued sides of veneer against an oil-paper separator. If crossbands are to be used, they would be mechanically glued on both sides and placed between the dry face veneer and the sawn lumber segment, still using oil paper between unglued faces. It is usual to use hand clamps in clamping together the entire block.

The position in which the veneers are laid up will depend somewhat upon the size. In general the vertical pile is quite unstable, and either an angling or horizontal accumulation is preferable.

Gluing With Fabric Bands. There are instances in which the nested form does not meet manufacturing conditions. Frequently, simple curved segments need to be longer than 22 in., the limit which can be band-sawn successfully. Segments up to thirds of a circle can be turned on a lathe, as is indicated in Fig. 7, in which three quadrant segments are shown mounted on a triangular arbor. These quadrants are usually attached at the ends where the hole will be trimmed off after veneering. It is customary to make the back side of these quadrants flat, rather than curved, since the hollowing out of the curved back is rather a difficult task. In the making of bow ends for cabinets or beds these segments usually need to be enough more than a quarter circle to provide a proper lip for framing. The back side is often out of sight and requires only strength and manufacturing convenience.

In the making of these lathe-cut quadrant forms, no female members result, for forcing the veneer in place. Female forms may be made on a lathe and used repeatedly, but ordinarily a stretched canvas clamp is used, as shown in Fig. 8. It is usually advisable to use crossbands in this type of gluing, although some authorities do not favor it. Tension in the canvas band produces sufficient pressure to bring the face veneer evenly against the curved base. The proper designing of clamp lever *E* will permit taking up the slack in the canvas belt as it stretches in service.

This process of clamping veneer to convex surfaces with flexible bands is a principle used variously in veneering round posts and columns with spiral wrappings of tape or bands. This work requires trained artisans of individual ability and is not mechanized to any extent.

BUILDING CURVED PLYWOOD

While gluing face veneer on solid band-sawn or lathe-turned cores is the historic and perhaps the easiest method of producing curved veneered surfaces, it has certain serious limitations, such as uneven thickness, size limits, and often may be of such a shape as to lack strength; i.e., the band-sawn core may split under the strain of usage.

Bending Plywood While Plastic. A process has therefore been developed in which freshly glued plywood may be pressed immediately between curved male and female forms, having equidistant spacing between all parts of the form when the pressure is at its maximum. This process requires an adequate number of rigid forms that are used over and over again, with generous throats or clearances for protruding edges of veneer and sufficient strength to withstand not only the repeated pressure, but also to resist the rough handling of continuous use.

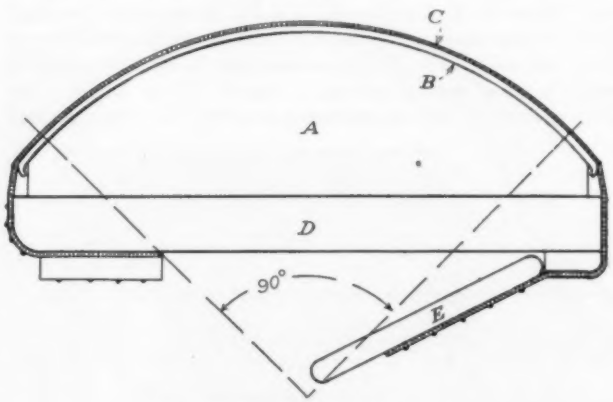

FIG. 8 CANVAS GLUE CLAMP
(To press veneer on lathe segments shown in Fig. 6. *A*, turned segment; *B*, veneer applied, with or without crossing; *C*, canvas clamp band; *D*, clamp block; *E*, clamp lever to hold canvas band tight.)

Veneer Requirements. Plywood bent under this process will consist of a number of laminations of relatively thin veneer, curved so that the grain of the principal laminations will be parallel to the axis of the cylinder represented in the face of the curve. This bending is called "with the grain." Thin veneer, $^1/_8$ in. and less, is preferable, since thicker veneer will show cutting checks. The resistance to bending "against the grain" of the veneer is considerable; consequently, the right-angle laminations must be as few as possible. It is important, however,

that the crossbands under the face and back should be bent at right-angles to the axis of the cylinder (against the grain), as this will add balance to the panel and will largely eliminate the tendency to "wind" which is so prevalent in curved shapes.

A typical design for a $^{11}/_{16}$-in. curved 9-ply door is shown in Fig. 9, in which $^{1}/_{8}$ in. is the maximum thickness and all veneers are laid parallel to the cylindrical axis except the two crossbands directly under the two faces and the center layer of $^{1}/_{20}$ in. The core is made of five layers, not true 5-ply, but an equivalent for a $^{9}/_{16}$-in. lumber core, that could not be bent.

In the case of $^{1}/_{4}$-in. curved plywood, the more conventional flat 5-ply construction can be used, as shown in Fig. 10. The grain of the face, back, and core are all parallel to the curve, with only the two crossbands at right-angles thereto. Adding another $^{1}/_{8}$-in. core, parallel to the face, would make a $^{3}/_{8}$-in. 6-ply.

It is preferable not to design a curved surface so that the face veneer has to be laid against the grain, since the wood permits little stretching or compression endwise. All veneers have considerable flexibility sidewise, due to their methods of cutting.

Face veneers, to be laid in curved forms, require more than ordinary preparation. Center joints need to be strongly taped as well as edge-glued. Cross tapes should be placed at both ends, and not more than 6 in. apart over the whole length. These will do much to prevent surface checking in bending and drying.

Standard commercial veneers will vary somewhat in thickness, due to shrinkage allowances made by veneer cutters, looseness of cutting, and pressure exerted during mechanical drying. The best manufacturers cut their green veneer about 10 per cent over standard, resulting in plump dry veneer. Mixing veneer from several sources is a hazardous proceeding, especially in plywood bending operations.

Male and Female Forms. The building of forms for shaping these all-veneer plywood curves requires careful attention and extreme accuracy, since any variation in the distance between the faces of the two forms under pressure will result in defective plywood. When forms are too close at any point, the pressure will be excessive, and plywood will have flat or hollow spots; when

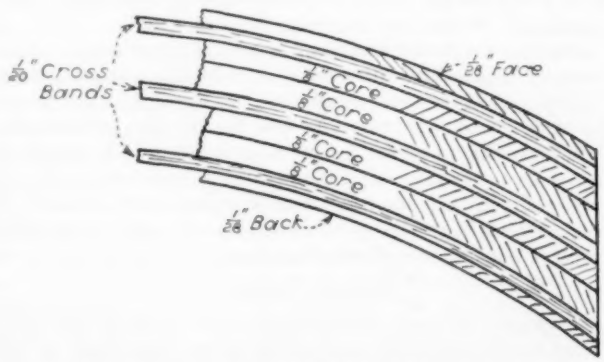

FIG. 9 CURVED DOOR, 9-PLY, $^{11}/_{16}$ IN. THICK
(All laminations bent with the grain, except the three crossbands; i.e., in the cross-section the end wood is exposed in face, back, and all cores, while the side wood is exposed in two outside and one center crossings.)

spots on the forms are too far apart, the veneer is likely to be loose at that point.

Lumber for use in these forms must be dense and hard, to withstand rough handling and to maintain even, smooth-faced curves. Maple and birch are ideal, but gum and poplar can be made to serve. The lumber must be sound and free from defects. End and edge joints, if well manufactured, are permissible, but must be carefully staggered.

Three types of forms are shown in Figs. 11, 12, and 13. In Fig. 11 the forms are made of laminated and crossbanded blocks, of a size and length that could be molded to curved shape on a four-side sticker, with a capacity of 12-in. by 6-in. stock. In order to successfully use this molder process, it is necessary to build these forms in multiples of length, not less than 4 ft. After the molding operation, it is necessary to carefully sand off the faces of the forms, with particular reference to removing any particles of end wood resulting from the cutting of the crossbands.

While it is possible to rely on glued joints to hold these forms together, it is preferable to bolt them firmly, as indicated, with $^{1}/_{2}$-in. bolts. These bolts do much to resist hard usage and to

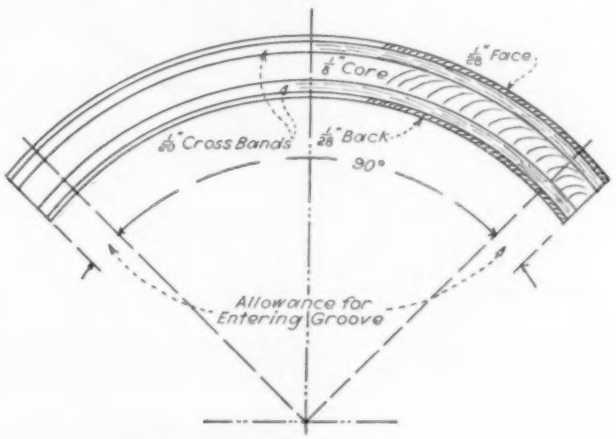

FIG. 10 CURVED PANEL, 5-PLY $^{1}/_{4}$ IN.
(Laminations have normal grain directions of ordinary flat plywood.)

keep the forms from becoming distorted in rough handling.

Authorities do not agree that the crossbanding is an advantage in this type of form. While it does increase the difficulty of obtaining a smooth cut in the molder, it also simplifies the gluing operation and adds much to the prevention of "wind" in the ultimate male and female forms.

The form shown in Fig. 12 is made with the grain of the wood running across the form rather than lengthwise, as in Fig. 11. The sections of this form can be roughed out on a band saw and brought to a smooth true curved face on a shaper. Some authorities advise gluing and bolting these laminations together, and others rely on bolts only, as indicated. There are instances, however, where a shaper might not be available, and such forms as shown in Figs. 12 and 13 might be made with a band saw and sanded after bolting together.

To secure accuracy in resulting curves, the distance between the forms is usually the thickness of a single unit of plywood, so the plywood curves will be uniform. There are cases, however, where plywood is relatively thin and accuracy is not so essential, so that the distance between the forms may be equal to two or three units of plywood. These units will have slightly varying curves in which the variations become less and less as the radii of the curves increase.

It is important in building male and female forms to provide sufficient and adequate clearances for excess veneer edges (to be trimmed off) and also wide enough throats at each side so that the surplus size of the veneers will not interfere with proper clamping under pressure.

Placing Veneer in Forms. Forms of the type shown in Figs. 11, 12, and 13 should be scraped and sanded smooth after bolting and thoroughly waxed before using. They should always be lined with waxed or oiled paper at each insertion of wet glued plywood to prevent the adherence of glue particles. Such glue particles should be immediately cleaned off, but at best are likely to mar the surface of the form.

Plywood to be bent in curved forms is glued and laid up as in ordinary flat plywood, but with two sheets of waxed or oiled paper between each unit. The units are carefully placed and centered in the lower concave form, with the convex form placed and centered above. Usually three sets of forms can be placed in a press retainer with flat caul boards between sets.

It is obvious that curved forms must be approximately balanced

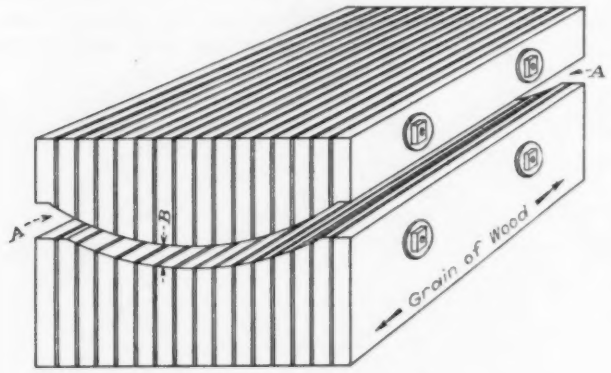

FIG. 11 MALE AND FEMALE FORM

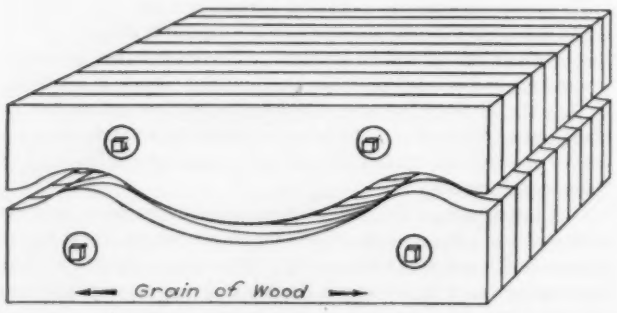

FIG. 13 MALE AND FEMALE FORM

(Curves cut on band saw, bolted together, and sanded smooth after bolting.)

on a center line in order that the wet plywood may not slip or slide under pressure. Attempts to anchor or provide guides for unbalanced forms have not been at all successful.

Multiple Forms With Crescent-Shaped Curved Cauls. There are instances where curved plywood may have shapes of approximate equality, such as opera-seat backs. In such instances it is found economical to design a series of male and female forms as shown in Fig. 14. Half a dozen plywood units may be placed in each opening, with curved cauls or separators between adjacent lots. These curved cauls are sufficiently crescent shaped to insure equal pressure at all points of the curved-plywood units placed between them. While it is conceivable that such multiple cauls could be made of wood, it has been found desirable to utilize the multiple system principally in those instances where production will permit the careful machining of metal cauls to true shapes. Such multiple cauls are more expensive than the single cauls, but they offer advantages in production where large quantities are required.

Drying Forms. The forms described have been those primarily designed for forcing the freshly glued plywood into the proper shape and holding it there for the initial set of the glue. Some manufacturers find that it is advantageous to provide sets of skeletonized forms for drying purposes, into which the curved plywood can be placed after removal from the gluing forms and rigidly held to shape during the complete drying out of glue water. These skeletonized drying forms will of course permit greater access to air currents and quicker drying, and will hold the curved form in the proper position until the drying out of the glue water has been completed. This practice is particularly necessary when curved shapes are large in area and relatively thin.

A common example of this practice is the gluing up of grand-piano rims, which are rather complicated pieces of plywood. Laminations are usually parallel without crossbanding, tending toward warping. The curve is quite complex, and drying forms are desirable.

Drying forms are sometimes used for curved veneer pieces, made from band-sawn, solid-lumber shapes, as described earlier in this paper. They are only necessary when a large amount of glue water needs to be dried out without distortion.

The use, however, of quick-setting, low-water-content glues has reached such a point that, in most instances, three hours in a gluing form will give a sufficiently permanent set, so that there is a minimum of distortion during subsequent drying. (See paragraph "Design and Inspection Tolerances.")

Crowned or Dished Plywood. It is possible to give a slight crowned or dished effect to plywood made by this process, in which the resulting plywood represents a slightly spherical shape. Such crowned plywood is frequently used for the tops of wardrobe-trunks, but if the crown is more than nominal, it is frequently necessary to remove narrow triangular sections from the different plywood layers to prevent crowding or lapping under pressure. A slight dish is usually given to veneered chair seats by the same process, but without removing segments.

BENDING PLYWOOD

Principles Involved. The bending of any piece of solid wood or of plywood involves compression of the wood fiber on the concave side and tension on the convex side. In other words, the fibers of the wood must all yield to a greater or less extent, either in compression or tension, except at the neutral axis.

The curving of plywood, previously described, was done when the glue was wet and the tension and compression had become slippage between the layers of veneer, and thus adjusted itself before the initial setting of the glue. The present problem of bending plywood after gluing differs in that the glue has had its initial set, so that it is necessary to stretch and crowd, not only the wood fibers, but the glue layers as well.

Most materials bend more readily and with less breakage when heated, and this applies to many organic as well as to inorganic substances. In the case of wood, its fibrous nature is an advantage in the bending processes, but heat must be used guardedly,

so as not to char the wood surfaces nor to make the wood brash and brittle.

Methods of Bending Solid Wood. It is essential to briefly mention the two principal methods of bending solid wood, in order better to visualize their application to plywood bending.

The steaming process of bending solid wood has been known for many years, and several approved methods have been followed in such products as agricultural implements, automobile and buggy tops, chair backs, wheel felloes or rims, and the like. Modern methods in this art, with attendant research, were fully covered in a paper on "Wood Bending," by T. R. C. Wilson, of the Forest Products Laboratory, published in Transactions of the American Society of Mechanical Engineers, Wood Industries Division, September to December, 1929. The problems there presented and the results accomplished are related almost wholly to the bending of steamed wood against the grain. One of the important fundamentals was the securing of the proper end pressure during the bending operation.

The dry-wood bending process is a comparatively recent development, not yet entirely beyond the experimental stage, but of proved practical worth. It is a process of selecting straight-grained wood, with a moisture content between 15 and 20 per cent (not kiln dried), and rolling it lengthwise between heated cylinders, in much the same way that sheet steel is rolled to produce curved boiler plates. It is obvious that some moisture will be developed and evaporated from the lumber itself, but no additional steam or moisture is applied as a pretreatment, hence the term, "dry bending." End pressure is not a matter of importance in dry bending.

Both the wet- and the dry-bending processes are applicable to plywood, but with considerable modification.

The Haskelite or Wet Process of Bending Plywood. This process of bending flat plywood into curved shapes in heated forms was named after its inventor and was first applied to the construction of plywood canoes, made from veneer with highly water-resistant blood-albumin glue. During the stress of the war period the process developed rapidly because of the suitability of such curved waterproof plywood for airplane construction. Commercial development since the war has been largely along the line of shaped and formed plywood for bus bodies and interiors, as well as for other curved industrial uses, where waterproof plywood quality was essential and where the cost of this process was not prohibitive.

In general the process is one of gluing plywood from sheets of veneer not more than $^1/_{16}$ in. thick, using blood-albumin glue as an adhesive. Blood albumin makes a two-stage glue; that is, the initial set results from the usual evaporation of glue water, and the final set is one caused by coagulation under heat. After the initial set of the glue in the flat plywood, the entire panel is soaked or steamed until the wood itself is highly pliable. This soaking can be accomplished without loosening the glue line, due to the qualities of the blood-albumin glue. The wet, pliable veneer is then placed between steam-heated male and female platens of the desired shape and forced into the curve desired under a temperature running between 160 and 220 deg. fahr. When this heat reaches the blood-albumin glue, it produces the coagulation or secondary set, which gives the plywood a permanent curve of the desired shape. The steam-heated platens also dry out the moisture in the plywood. This process is closely protected by patents and is not extensively practiced, but the essential steps are fundamentally as outlined. The resulting plywood is an excellent but costly product.

Dry Process of Plywood Bending. The wet process of plywood bending is limited to the use of blood-albumin glue, and cannot be accomplished with animal, vegetable, or casein glues. The dry-bending process, however, is fully as applicable to plywood as it is to solid wood, and with essentially the same equipment.

The roller bending machine is shown in outline in Fig. 15, in which cylinder *D* is rigidly held in position at its bearings, which do not require vertical adjustment. The interior of this cylinder is heated through perforations in an illuminating-gas pipe *E*, extending the whole length of the cylinder. The diameter of this cylinder may vary somewhat, according to the radius of the material to be bent, although the range of radii that can be bent on the one size cylinder is considerable.

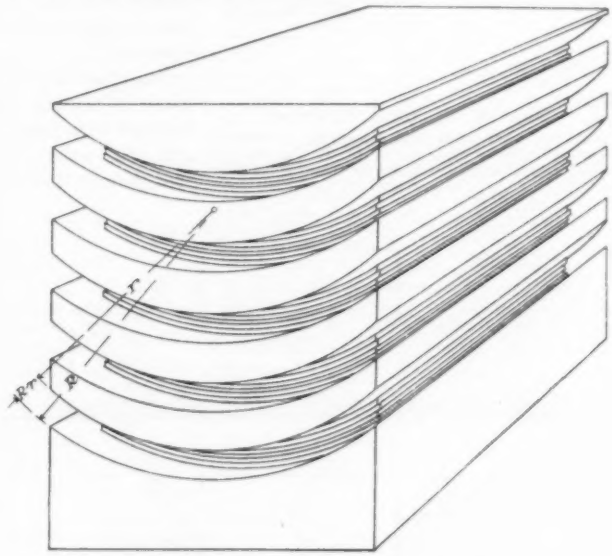

FIG. 14 MULTIPLE MALE AND FEMALE FORMS

(Producing approximately similar shapes. Preferably made of metal, R, outside radius of largest unit; r, inside radius of smallest unit; $r + R/2$ average radius; $R - r$, distance between cauls.)

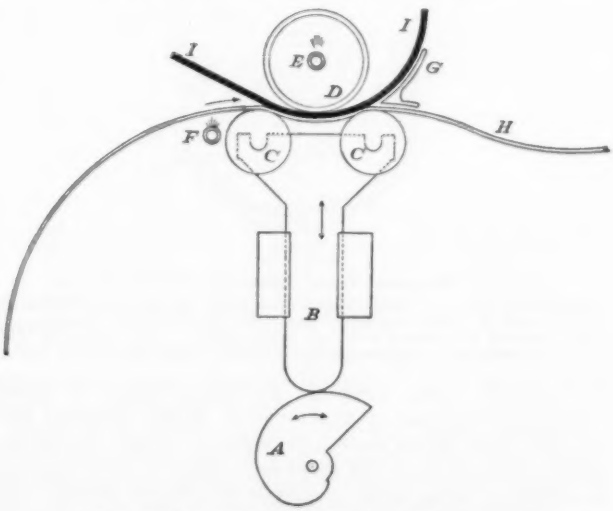

FIG. 15 ELLIOTT DRY-BENDING MACHINE

(*A*, pressure adjusting cam; *B*, adjusting bar; *C-C*, lower roller supports; *D*, upper heated roller; *E* and *F*, perforated gas pipe; *G*, guide; *H*, flexible metal band; *I*, plywood under bending.)

The pressure exerted on the plywood to be bent is regulated by cam *A*, which in turn forces the idle rollers *C-C* closer to the live roller *D*. Between idle rollers *C-C* and live roller *D* is an endless steel belt *H*, usually made in strips not over 6 in. wide. This belt serves to convey the plywood under live roller *D* and over idle rolls *C-C*. In some instances idle rolls *C-C* are heated with internal gas lines, and in other cases the heat is

applied at *F* under the moving steel bands. The plywood must be kept hot on both sides. The curved guard *G* is to keep the bent plywood from following the steel band and is adjustable; in operation it should touch the curved panel as it leaves the rolls. The piece of plywood to be bent is indicated at *I* in heavy black line. These bending machines are made in several sizes and, due to the slow speed of operation, are usually designed in duplicate or quadruple units, to take two, four, or more pieces of plywood simultaneously, thus economizing on the time of the machine operator.

FIG. 16 FLEXIBLE PLYWOOD

(Face and back bend with the grain. Center is made as thin as possible, 1/16 in. to 1/24 in., to offer a minimum resistance to bending against the grain.)

Great care must be taken in feeding the flat plywood squarely into the rollers, so that there will be no faulty spiral or wind resulting in the machine-curved pieces.

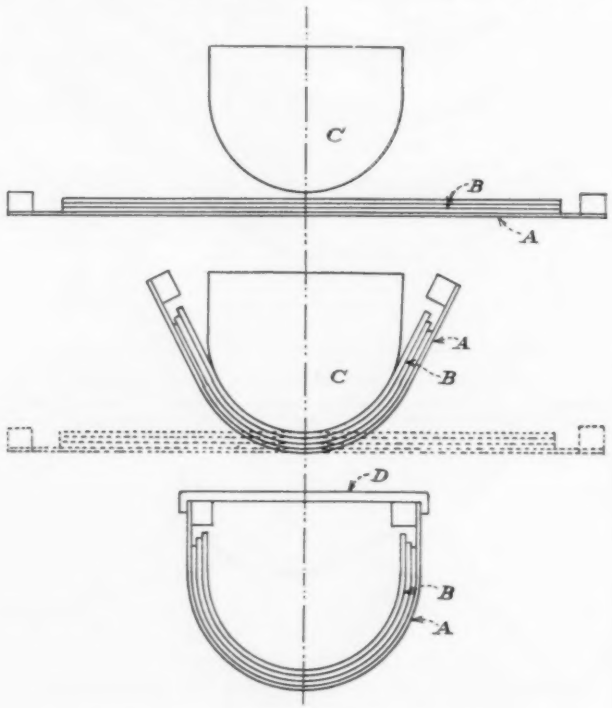

FIG. 17 BENDING WITH FLEXIBLE METAL BANDS

(Upper view shows plywood ready to be bent; center, plywood partly bent; lower, plywood completely bent, removed from the machine, and bands clamped as a drying rack. *A*, metal band; *B*, plywood to be bent; *C*, forming die; *D*, clamp to hold plywood *U* in shape until dry.)

Bending machines of this type are usually equipped with variable speed drives, since it is desirable to heat the machine gradually and to make the speed dependent on the temperature available, as well as on the thickness and moisture content of the plywood to be bent.

It is impossible to do bending of this character in a rapid manner, since the yielding (stretching and compression) of the wood fibers and glue strata must be gradual and without sudden jolts and jars, which would shatter the wood or tear it away from the glue lines.

Some authorities advise machine-bending plywood before sanding, although the lines of paper tape may make some indentations which will sand out. Others advise bending after sanding, in which instance some type of efficient cleaner must be attached to keep all small particles of dust away from the heated rollers and steel belts, and thus prevent denting or marring the surface of the plywood. Where the finished face of the panel is on the convex side, it is highly desirable to leave the tape in place and add its restraining influence to prevent either the cracking of the face veneer in stretching or the opening of the joints. Where the finished face is on the concave side, the absence of the paper tape will do no harm.

Machine bending under this process requires as high a temperature as can be used without either burning the wood or destroying the adhesiveness of the glue. In general the best success has attended the use of casein glues, which are low in lime content and therefore not as brittle as the more thoroughly water-resistant brands. The most successful bending is done within two days after gluing; further delay increases the hazard of tearing the plywood on the glue line. Animal glue will not endure such high temperature, and vegetable glue has not proved satisfactory.

It is desirable to have drying or tempering racks in which to place the bent panels after machine bending and during their cooling. Any tendency of the curves bent on this machine to straighten out occurs within this cooling period, and if the bent plywood is held true until cool, it will seldom change shape afterward.

It is a peculiarity of this type of bent plywood, as well as a distinct advantage, that it is more limber and more easily forced into mechanically shaped grooves than is plywood curved in the press while the glue is wet. Curves up to 240 deg. may be bent under this process.

The use of this bending machine results in substantial economy in utilization of material, since much narrower trimming allowances are required than in the case of plywood curved in forms while wet. On small panels this saving may be as much as 10 per cent.

The dry-bending process for plywood is too new to permit any comprehensive idea of its range of usefulness. It is entirely successful on 1/4-in. 5-ply panels and has been operated without serious difficulty on plywood up to 1/2 in. in thickness where all of the layers were of veneer rather than solid lumber. Whether it will operate with equal success on thicker plywood or plywood with lumber cores is a problem yet to be determined.

The development of bending machines of this type is in its infancy, the principal pioneer being C. W. Elliott, of Columbus, Ind., whose machine is described in the foregoing. The possibilities of further improvements along this line are decidedly challenging.

OTHER MINOR PROCESSES

Flexible Plywood. Flexible plywood is another type of construction in which only 3-ply can be used. The core or center is very thin, with the grain across the curve, as shown in Fig. 16. Two faces make up the required thickness with the grain parallel to the curve. Such flexible plywood must be made of very loose-cut veneer and is not suitable for figured veneer or highly finished. It has been extensively used for curved sleigh dashes, horns for phonographs, and other curved surfaces where flexibility is essential and appearances are not important. The principle of this flexible plywood is found in the 5-ply core of the curved door shown in Fig. 9.

Bending Plywood With Flexible Metal Bands. In Mr. Wilson's paper, referred to in the early part of this article, Fig. 8 illustrates a rim-bending machine particularly adapted to the bending of solid-wood wheel rims and other semicircular shapes. An outline of this process of bending, applied to plywood, is indicated in Fig. 17, the upper portion showing three strips of veneer, with either parallel or angling grain, laid on a thin metal band. The action of the machine is such as to draw this thin metal band and freshly glued plywood around a sturdy, rigid form resulting in

the bending of the plywood to the shape of the form or die. It is arranged so that a clamp or double hook can be placed across the U-bend, to hold the curve in proper shape until it has been thoroughly dried and the curve fixed in position. This type of plywood bending is limited in scope, but is applicable to the bending of plywood rims and subrails for circular table tops. It was in extensive use when round dining-room table tops were the prevailing style. The machine is expensive to install and operate and requires costly dies for the different curves; hence it is only suitable for large production schedules of standard curved units.

Design and Inspection Tolerances

Mechanical uniformity in curved plywood shapes, even those most accurately made by any of the processes described, can be only approximate. Physical differences in the lumber and veneers, as well as inevitable variations in manufacturing procedure, will make some curves subsequently flatten out or curl up more than others. Curves piled in a hot or moist place may change shape more than those piled in a cool or dry place. Designers and users of curved shapes should therefore make due and reasonable allowances for such unavoidable variations. Thin curved plywood in the ultimate product should be set in reasonably rugged frames or be firmly attached to a sturdy member, permitting a reasonable amount of forcing into place.

Inspection tolerances should be drawn with reasonable liberality, since too rigid limits will cause a high percentage of rejections and influence cost prices.

Trimming and Sanding Curved and Bent Plywood

Trimming Ends and Edges. The trimming of the edges and ends of plywood curves, produced by any of the processes described, presents some rather interesting and complicated sawing problems, particularly as the edges usually need to be sawed on radial lines, after making allowance for inserting in frame grooves. Both ends and edges must be trimmed with the minimum of tearing in the face veneer. Where edges are parallel, as in Fig. 9, the task is easy on standard twin saws, equipped with a saddle on the sliding table between the saws. Radial edges are much more difficult, and usually require saws located on the convex, rather than on the concave, side of the curved piece. Much ingenuity has been expressed in the type of cradles or holders to be placed on the double cut-off or equalizing saws, as well as on the double rip saws.

A large production would justify the building of swivel twin trim saws with sliding table between, since no machinery manufacturer seems to have provided adequate equipment for this operation.

Sanding Equipment. As in the case of sawing, this operation has required a variety of machine attachments to facilitate safe and speedy work. An oscillating saddle is shown in Fig. 18, which can be mounted on the sliding table of a belt-sanding machine and will adapt itself conveniently to the sanding of the outside of convex surfaces without unduly stretching or straining the sand belt. Pressure block *C* may have a concave surface, although such surfaces are dangerous and not desirable unless absolutely necessary. The ordinary flat under-surface is best for this block. Sander belts may be reduced to about 4 in. widths for curved surfaces and in some difficult instances may be made of cloth rather than paper. It is desirable to use the underslung rather than the overslung type of belt sander, since the latter interferes with the manipulation of the saddle and the curved plywood.

In some instances, however, the interior, or the concave side, of the curved surface must be sanded, and a cradle for doing this is shown in Fig. 19. This is practically the reverse of the saddle shown in Fig. 18, but needs careful operation to avoid a conflict between the sand belt and the oscillating shaft of the cradle.

Where doors are to be sanded on both concave and convex surfaces, it is possible to make a combination saddle and cradle,

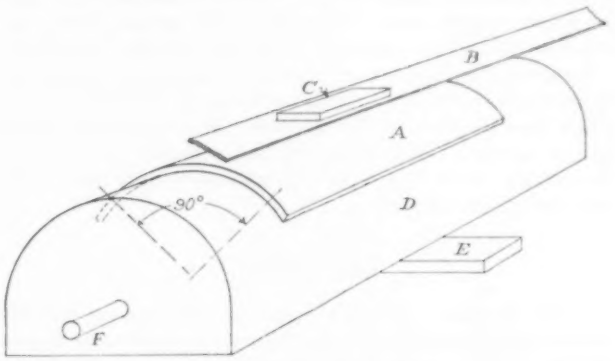

Fig. 18 Saddle for Sanding

(*A*, curved plywood to be sanded; *B*, sand belt; *C*, sander block; *D*, oscillating saddle; *E*, operator's handle for swinging saddle while sanding; *F*, saddle shaft.)

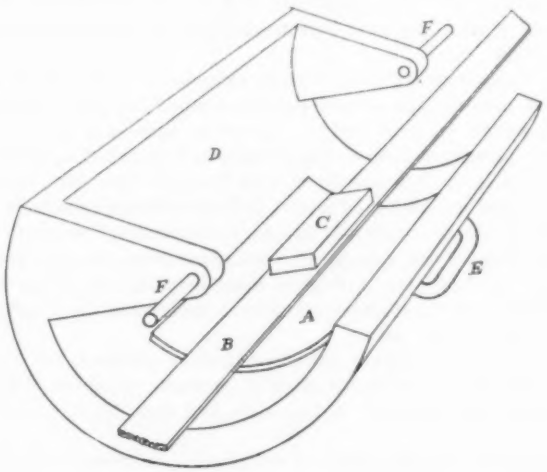

Fig. 19 Cradle for Sanding

(*A*, curved plywood to be sanded; *B*, sander belt; *C*, sander block; *D*, rocking cradle; *E*, operator's handle to rock cradle while sanding; *F*, cradle shaft.)

with suitable curved beds upon which each side rests during sanding.

The sanding of serpentine fronts can seldom be aided much by attachments and is best done by laying the curved plywood directly on the belt-sander table.

There are a number of special sanding machines made for curved chair stock, but in most instances these contemplate that the grain runs across the curve, and hence not in the proper direction for sanding curved veneer and plywood surfaces.

Conclusion

The various processes of producing curved veneered shapes have been outlined at approximately the present state of the art. The author realizes keenly that much research and experimentation remain to be done and that the present processes, now limited in their scope, may be greatly extended, and that prevailing cumbersome steps may be eliminated entirely by future developments.

It must be clear that there are great possibilities of extending

the scope and usefulness of curved plywood, not only in the making of artistic products for use in pianos, radio cabinets, and the like, but also in the design of a wide range of utilitarian products where curved plywood can be advantageously adopted.

Plywood can be adapted to many new and original purposes with its desirable qualities of bulk, reasonable resiliency, and high strength-to-weight ratio. It was repeatedly proved during the war that pound for pound plywood was stronger than steel.

Research along the line of making wood products water- and fire-resistant are rapidly overcoming these two limitations under which wood has labored for many years. Wood in its many forms has an unusual industrial appeal and certainly will hold an increasingly larger place in the utilitarian branches of the manufacturing industries.

Discussion

C. W. Elliott.[2] The description in this paper of the plywood-bending operation has not fully covered the range of possibilities that the writer's experience has revealed. While the development of the dry-bending machine has been largely along the lines of solid wood, the writer's experience has proved that practically all of the operations and products that can be made from solid wood can be made with even greater effectiveness from various types of plywood that are designed for bending-machine operations.

The wood-bending craft, with an extensive natural resource as its raw material, has not stepped up as rapidly as other branches of industry in past years. However, enhanced largely by canny inventions, time-saving devices, and perfected equipment, today it is making greater strides forward than ever before. As in other industries, advanced and more efficient methods are being introduced currently in the wood-bending business.

Possessed of many years' practical experience and trail blazing in this revolutionary method of wood bending, the writer feels qualified to give authentic information concerning the industry's progress in recent years.

Prior to inventing the dry wood-bending machine, the writer was engaged in the manufacture of products requiring the use of hoops and circles of various sizes and from $^1/_4$ to $^3/_8$ in. in thickness. The steam-bending process was used, and many difficulties were experienced, such as slow production, uneven curves, considerable breakage, and high cost of equipment.

While using the steam-bending process the writer conceived the idea of dry bending by machine, a radical departure from the conventional methods then in practice. He designed and built the first machine of this kind. When completed and placed in operation, the results far exceeded expectations, and the future possibilities were seen. It was apparent that it produced a better quality of bent work with truer curves. The loss by breakage was practically eliminated, and the cost was reduced to approximately one-half.

Later the work of developing a machine for the bending of heavier material was undertaken. Innumerable difficulties were encountered in solving the problems accompanying the bending of this heavier material. Means were needed for greater contraction of the inner curve and better control of the outer curve. Through a long period of experimenting, many devices were tried until the desired result was accomplished in a fairly satisfactory manner.

With machines in operation for bending the heavier stock along with the lighter material, the writer's company entered the field of custom bending, manufacturing bent-wood stock for many purposes. The material ranged in thickness from $^1/_8$ to $^7/_8$ in., and the radius from $3^1/_2$ in. to 7 ft.

In the custom-bending field both solid material and plywood were bent. However, the machines had insufficient scope to meet all requirements of bent stock needed in the woodworking industry. It was found that further development of improved machines for producing various shapes and compound bends would prove of great benefit to the industry, and were greatly needed.

Work on machines to produce this type of work is progressing. Many experiments have been made in recent months, and the results are proving quite successful. It is hoped to have these machines perfected in the near future.

A class of work is being produced by machine bending which heretofore was prohibitive, even by the method of gluing in male and female forms. This work includes complete circles with butt joint, semicircles or other shapes of uneven thickness, and complete circles with scarf joint. (See Fig. 20.)

Plywood and solid wood of $^3/_4$ in. thickness can be successfully bent to a radius of 18 in. on the new type of chair-back machine.

Standards and Tests for Coated Abrasives

By E. C. SCHACHT,[1] TROY, N. Y.

The paper presents some of the standardization measures which have been undertaken by the sandpaper industry, tracing their evolution and influence on the product. Typical factory-control methods used in the manufacture of coated abrasives are described, together with testing media for evaluating the cutting efficiency of the finished product.

THE World War supplied the real centralizing, coordinating force in present-day industrial standardization. It stands today as an accepted economic institution, and yet generally there is little true realization or appreciation of its broad significance. The user of a commodity manufactured by an industry practicing cooperative standardization comes in contact usually with just one phase of its operation; namely, the elimination of unnecessary sizes, grades, items, etc. This contact in many instances produces an unfavorable impression because of the element of personal sacrifice, and it accounts for the occasional minority conception that standardization is a boon solely to the manufacturers of the article in question. By showing the purchaser or user the benefits which one particular industrial standardization confers on its trade, his cooperation can usually be obtained and real progress be assured.

In the sandpaper industry, the individual manufacturers have long appreciated the results of cooperative effort in eliminating unsound manufacturing practices and wasteful methods. That the user of sandpaper has profited by the development of the industry is certain, for there is a good way to judge the average improvement of the product and its increased production during the last 13 years. The quantity or reamage of sandpaper sold in the United States last year was nearly the same as in 1916. Therefore, over that period there has been little growth in the volume of sandpaper made. Over the same 13 years, however, the general increase in demand for basic materials has been about 70 per cent. The general economic growth of the country should have required about 70 per cent more sandpaper if the quality had remained the same. In addition to this, there have been new industries and uses that would have required, say, still 30 per cent more sandpaper. The total increase in sanding work to be done in 1929 was probably close to 100 per cent over 1916. It is certain that this increase in demand has been supplied by the improvement during 13 years of nearly 100 per cent in the quality of sandpaper. The increase in production per unit of area has been so great that no buyer of sandpaper used in production would today accept the product of 1916.

One specific instance of quality improvement will serve as an illustration. The fir veneer and door industry on the Pacific Coast uses six- and eight-drum sanders to finish and bring fir veneer to gage. The first or roughing cut is usually made with No. 3½ garnet combination, followed by finer grades of paper and combination coated with either garnet or aluminum oxide. Ten or twelve years ago as low as 4 hours' production was obtained from the first or coarsest cover, whereas today some plants have reported as high as 96 hours' continuous production from the present-day product which has been specially developed to meet the requirements of this very severe duty.

The decrease in the yearly consumption of sandpaper is not due to the fact that sanding is being replaced by other methods. It is not possible to prove this contention statistically, but close observers in the business can see no curtailment of old uses, but instead a development of new ones, notably floor-sander applications, waterproof sandpaper, and fiber disks for portable sanders in the automobile industry.

While the sandpaper industry has been cooperatively working out standardization measures, the individual manufacturers have been developing factory standards, control methods, and means of testing and evaluating the performance of the finished product.

Standardization in the Industry

Just a generation back each of the sandpaper manufacturers was making his product, which consisted of several hundred total items without any well-defined standards for his own plant and a complete lack of standards within the industry. The specifications for the product were continually being shifted and largely for competitive purposes.

The gradual development of the grading standard is interesting. Heretofore each manufacturer varied his grades or grain size for a given number as a competitive attack or defense. A single manufacturer would have in stock several different grades of the same number. Desiring to obtain the business on an item, his first move would be to select from his several variations of that number one slightly coarser than that of his competitor in order to increase the production. Or if the trouble was scratching, where possibly his competitor had been using a coarse variation, then he would recommend some of his finer gradations of the same grit number. The possibilities of error and trouble for his customer were obvious. The customer could not buy a competing brand without submitting a sample to match the grade. Under these conditions, of course, none of the grades was any too good. (See Figs. 1 and 2.)

The first attempt of the manufacturers to establish a uniform grade consisted in selling sheets of material by appearance and feel. That gave some pretense of reasonable grade spacing. When he chose to do so, the manufacturer would attempt to match this sheet. Later, silk testing sieves were designated by mesh number, and a rough specification for grade was thus set up. The difficulty with this method was the variation in sieves of the same mesh number. The next step was to establish standard sands for the most-used commercial brands. At this time there were still different grading standards for the various abrasive minerals used. Silk testing sieves were carefully selected, and a sufficient quantity was given to each manufacturer. A standard method

Subsequently, he pursued special studies at Carnegie Institute of Technology and at Stevens Institute. He served as Lieutenant (J. G.) in the Navy during the war. Since 1920 Mr. Schacht has been in the sandpaper business. He is a co-author of "Direct-Current Motor and Generator Troubles."

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

of screen analysis was set up so that different operators could check each other. Specifications were established for the amount of under grade, control grade, and over grade for each grit size. These terms are explained as follows: In a series of abrasive grades an individual grade is determined by two screens, one known as the fine screen and the other as the control. If the grain is shaken on the control screen, the portion that remains on the control screen is known as the "over grade," the portion passing through the control and remaining on the fine screen is known as the "control grade," and the remainder (i.e., the portion that passes through the fine screens) is known as the "under grade." The over grade is not greatly different in size from the control grade since it must be retained on the control screen of the next coarser grade. Likewise the undergrade must not pass through the fine screen of the next finer grade.

An attempt is made to keep the control grade as large as possible. The control screen of any grade acts as the fine screen of the next coarser grade, and the fine screen acts as the control of the next finer grade. (See Fig. 3.)

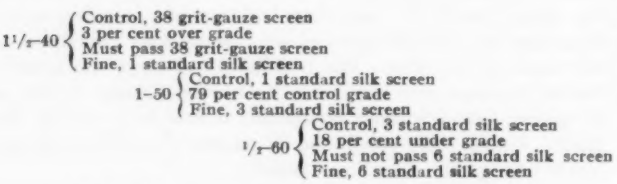

FIG. 3 DIAGRAMMATIC SCHEME OF CONTROL SCREENS

More recent refinements have come from the study of the size of apertures in silk sieves and specifications for sieve mode point. The method of determining the screen mode point consists of measuring the average size of 1000 openings by projecting the silk to be measured by means of a balopticon and measuring the projected screen image, averaging both dimensions of openings. Knowing the magnification factor of the lantern, these dimensions are converted back to ten-thousandths of an inch. A curve of size of opening versus per cent occurrence is then plotted. The mode point is the opening which occurs the greatest number of times. A mode curve of No. 11x–116 mesh silk is shown in Fig. 4.

Another method of particle-size measurement which gives reliable checks, but which requires a great deal of skill by the operator, consists in carefully calipering the vertical height of grain between surface plates.

By measuring the rate of fall of mineral in different fluids and assuming that Stoke's Law holds, an average particle size has also been determined. For fine grits methanol has been employed in order to decrease the time of the test, while for coarse grits a settling fluid of high viscosity such as glycerol has been used in order to decrease the time of fall to a measurable rate. For intermediate grits liquids having viscosities intermediate between methanol and glycerol are necessary.

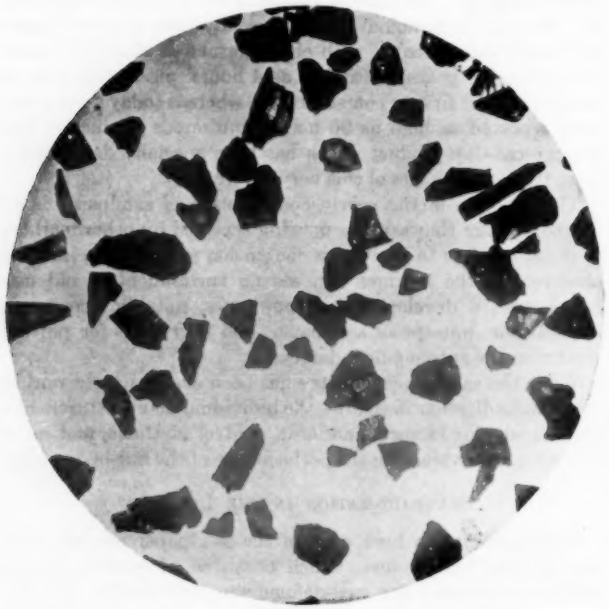

FIG. 1 A POORLY GRADED GRAIN

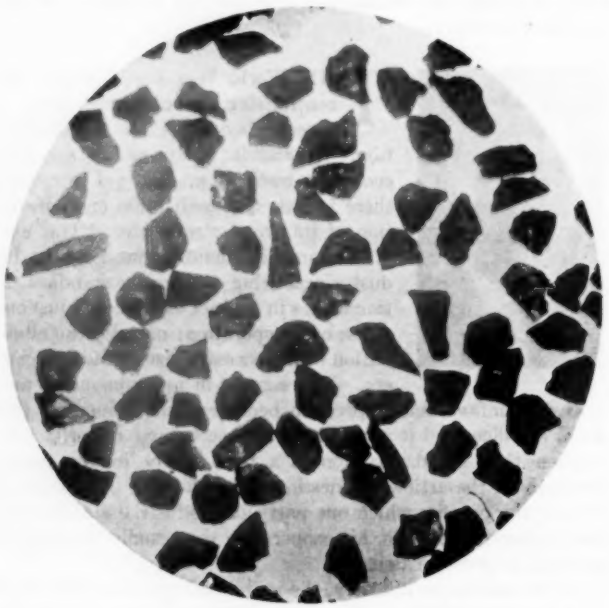

FIG. 2 A WELL-GRADED GRAIN

A uniform grade spacing for the important wood and metal-working abrasives has been worked out, so that now similar grade designations are employed on garnet, aluminum oxide, and silicon carbide. The grades as finally developed in the industry show a very fair grade spacing from one size to the next. For example, the following vertical height measurements were secured by calipering the maximum heights of aluminum oxide grain in the control portion of each grade. The measurements were made by calipering the grain between level steel plates and are expressed in ten-thousandths of an inch.

Mesh number	Grain height
400	12
320	20
280	25
240	33
220	40
180	45
150	50
120	64
100	80
80	105
60	140
50	175
40	215
36	260
30	310

Mesh number	Grain height
24	360
20	460
16	600
12	800

The standard sand and the analytical method have practically eliminated important grade variations as a problem to the user.

Similarly, paper and cloth backings have been studied, and the best practices have been determined. Fifteen years ago 14 different weights of paper backing in three different qualities, or a total possible combination of 42 paper items, were used. Today there are 8 standard weights of paper and a single variety for each class of product. The reduction in the number of items has increased the consumption of each class, so that the manufacturers of paper for the sandpaper trade can profitably devote research effort and provide special equipment to improve the product. Standardization programs have been conducted with the manufacturers of both rope and kraft papers, and limiting specifications have been adopted governing such factors as selection of samples, weight determination and tolerances, thickness, tensile tests, length and cross, air resistance, adhesion, color, moisture content, finish, and formation. By enlisting the cooperation of the paper manufacturers and acquainting them with sandpaper problems and the performance of their product in the field, remarkable results have been obtained. Rope paper, such as is commonly used for belts and drum covers, has been increased in length tensile strength from an average of about 85 lb. per in. to 150 lb. per in., and the adhesion of cylinder rope paper, which is the property which in a large measure controls the peeling of sandpaper, has been improved approximately 50 per cent.

At the present time a program is being worked out with the cloth manufacturers, and their aid is being enlisted in such measures as the adoption of weight, count and construction specifications, the reduction of stretch, the elimination of defects which must be cut out, and the increase in the length of cuts of cloth. The two latter measures will reduce the number of splices or breaks in the finished product. The work with the cloth manufacturers will necessitate their education in sandpaper and its uses. Customers of the sandpaper industry will eventually reap the benefits of improved cloth design and construction revealed to them in improved performance and condition of the finished product.

Some of the other industry standardization measures beyond those on abrasive grades and paper and cloth backings are as follows:

The elimination of dye in coatings to produce a uniform appearance, which makes it easier to substitute one brand for another without prejudice. Ordinary flint paper, which is normally light yellow in color, has in the past been dyed red to imitate garnet and has also appeared in shades of green and purple.

Coating classification and weight tolerances to guarantee a reasonable uniformity of coating from lot to lot and from one manufacturer's product to another. Tolerances within reasonable limits govern the standard weights of mineral used in making the two accepted coating variations, namely, closed and open coat.

Standardization of special shapes such as heel breasters, Websters, cones, etc. (In some of these cases it was necessary to cooperate with the machine manufacturers to get them to make equipment which conformed to the standard sizes.)

Improved ream and roll packings designed as a result of group experience and thought to more adequately protect the sheets and rolls of sandpaper in shipment to the customer.

Uniform quantities per bundle in ream goods.

Standard belt-joint specifications and many others.

Advantages of Standardization

The value of the standardization that has been carried out in the coated-abrasive industry has been very great to the user. Instead of being concerned with the determination and the analysis of a large number of factors of competing varieties of sandpaper, the user now has to concern himself with practically only one question which he must always determine for himself, and that is the cutting capacity or work-producing ability of the materials which he can obtain. The standardization program in the industry has almost eliminated the question of finish, although this must always exist to some extent due to individual skill and methods in cutting. The primary problem of the sandpaper purchaser is that of determining the cost of abrasive material per unit of product which he is turning out of his plant, which may be per square foot of veneer, or per desk, or per automobile, and the purchaser can put nearly all his effort into finding the right answer to this question.

The purchaser has in effect a set of rigid specifications, all prepared for him, that have taken more time and study to prepare than a single purchaser could devote to the subject. He need only specify in the briefest terms the material that he requires, and he is assured of uniform materials, weights, and gradings and that he will receive from practically every manufacturer a commercially comparable article so far as it relates to these several points.

There are, of course, among all of the manufacturers of sandpaper, differences in the use of materials, skill in manufacturing

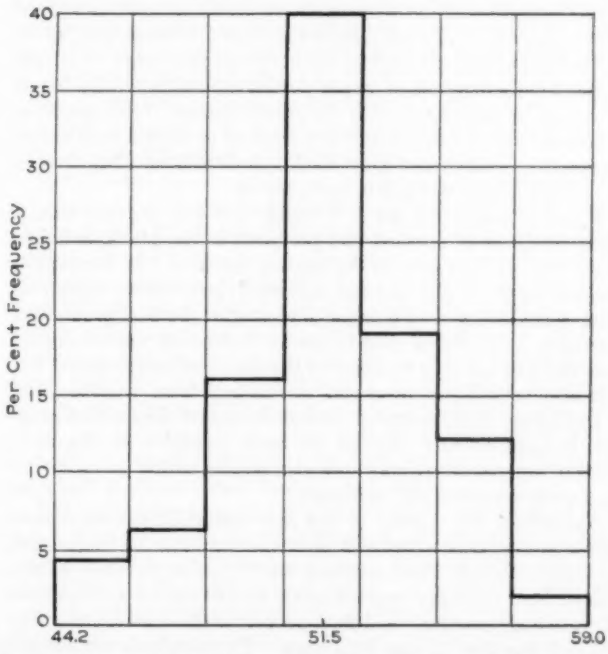

Fig. 4 Sample Mode Curve Illustrating Sharp Mode Point

methods, accurate control of the materials themselves, control of manufacturing operations, and the knowledge that comes from research and more indirect details of operations; differences in perfection of equipment—all of which make for very considerable variations between the working qualities of the product from one manufacturer and another, leaving a strong individuality of product in the industry that of course never disappears under any standardization program. The sandpaper manufacturer today finds himself in possession of excellent specifications for the principal materials, weights, and gradings. His

next problem therefore is the successful application of these standards to the most profitable control of operations in his own plant. This problem is worked out in different ways by the different manufacturers. The following will indicate the methods that are used by one manufacturer in putting his standards into actual operation.

Quality Control in the Sandpaper Plant

Paper backings are purchased which exceed the minimum limits adopted as industry standards. The competition in the paper industry affords the sandpaper manufacturer an opportunity to continually select paper whose tests far exceed the minimums established and to segregate for particular purposes paper having variations of such qualities as finish, softness, etc., which will suit it particularly well for use in certain products. A sample is cut from every roll of paper purchased and carefully tested to assure its agreement with the specifications. Grey goods as it arrives from the cotton mill is subjected to careful tests before acceptance. When the grey cloth has been finished or treated to prepare it for coating it is again tested.

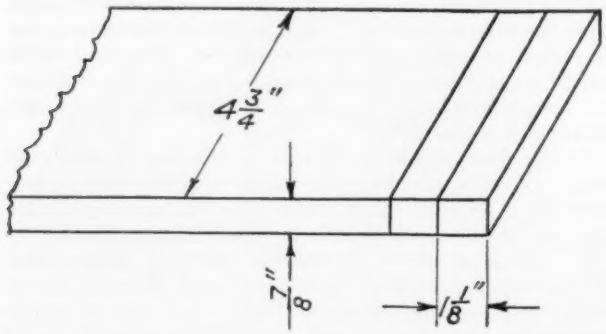

Fig. 5 Method of Cutting Test Blocks From Oak Boards

Abrasive grain, whether it is bought finished to grade from a grain producer or crushed and prepared in the plant, is finish-graded before it is sent to the coating machine. It is carefully checked for its ability to bond well with the adhesive employed. Each container of sand is check-graded after the final production screening by a control man to assure that every yard of coated material will not only conform to the standardization limits, but will also be uniform from run to run and from year to year.

Hide glue, which is one of the constituents of the finished product, is sampled and checked for such qualities as viscosity, acidity, deterioration, jelly strength, and its ability to be coated on a sheet smoothly and uniformly.

Assured of the quality of the raw materials, the sandpaper manufacturer must select and maintain standards for the finished product. An individual standard must be selected for each item coated (and there are approximately 478 items) by a committee of technical, practical, and field people in the organization who are well qualified to pass judgment. The standards are subject to a constant and continual revision based on performance reports of factory and field tests which insure a constant elevation of the quality. The standards are placed in charge of the Quality Control Department, manned by technical men. Each standard is in an individual envelope which carries complete and detailed specifications governing the manufacture of that item and is issued to the coating department immediately preceding the making.

After the proper standards have been set and a means provided for their maintenance, it is necessary to insure that the product is fabricated within the limits which have been imposed. A member of the Quality Control Department is present at each making and takes samples at regular intervals. The weight is continuously indicated by a continuous weighing scale, temperatures of all baths, etc., are automatically held constant, and the proper humidity and temperature regulation is automatically maintained in the drying compartments. Samples from the run are placed in individual envelopes containing all pertinent data and are kept on file by the Quality Control Department. Before filing, all samples are carefully examined, analyzed by the laboratory, and checked against the standard.

Periodically samples of all runs are spread out and reviewed for uniformity. All comments received from customers are considered and noted on the run envelope. Each month field performance reports, complaints, and general product experience is reviewed by the Quality Control and the Technical Departments with a view to the constant development of the product.

The foregoing outline gives merely the salient features of the control methods employed in sandpaper manufacture and in no way indicates the experimental, research, and developmental work which is constantly being expended on raw materials equipment, and manufacturing methods.

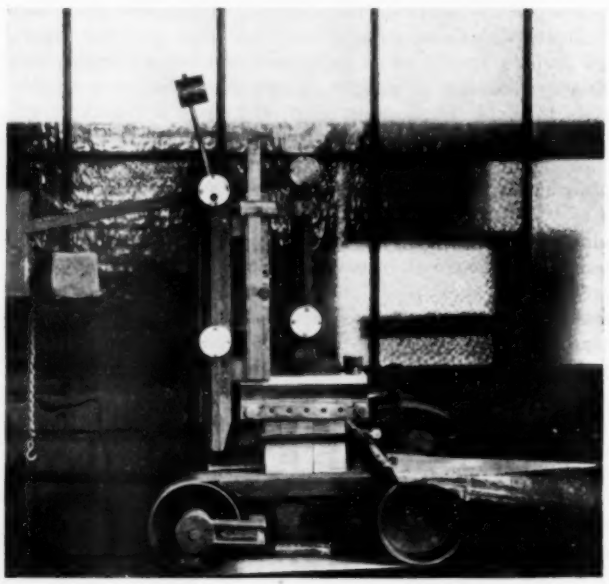

Fig. 6 Photograph of Belt-Testing Machine

Factory Testing of Sandpaper

From the Quality Control Department, the finished goods pass to the Testing and Inspection Department, which determines the performance rating and releases the goods for finishing and distribution if it is up to standard. The user is naturally most interested in the testing of the finished product, for he is concerned with the ability of the sandpaper to best do his job. He must, however, give due regard to the refinement of manufacturing operations, for it is this refinement which guarantees, not spasmodic making of a satisfactory product, but one which will constantly give uniformly good results. In the last analysis, sandpaper is only a tool, like a drill or a saw. Sandpaper is not generally used mechanically, but instead its use is attended with an expenditure of labor of far greater value. For this reason, either continued testing or performance checking should be resorted to, to evaluate the product, either by the sandpaper manufacturer or the user, or by both. Experience has shown that too often changes are made involving sandpaper as the result of a single test in which the variables in the conditions

surrounding the test were greater than the variations in the sandpaper itself.

In the factory tests a duplication of the conditions of field usage would at first appear to be the best method of testing. There are, however, in the case of woodworking materials several reasons why this cannot be done, the two outstanding, of course, being the time required and the material consumed as would be especially true in the case of drum sanders. It is necessary, therefore, to determine upon a test that will give a rating of the sandpaper which bears a relation to its rate of production in actual use.

Three varieties of testers are in common use on woodworking materials, namely, disk, belt, and reciprocal. The data secured on these machines have thus far proved very reliable, and while still the subject of refinement and development, the agreement

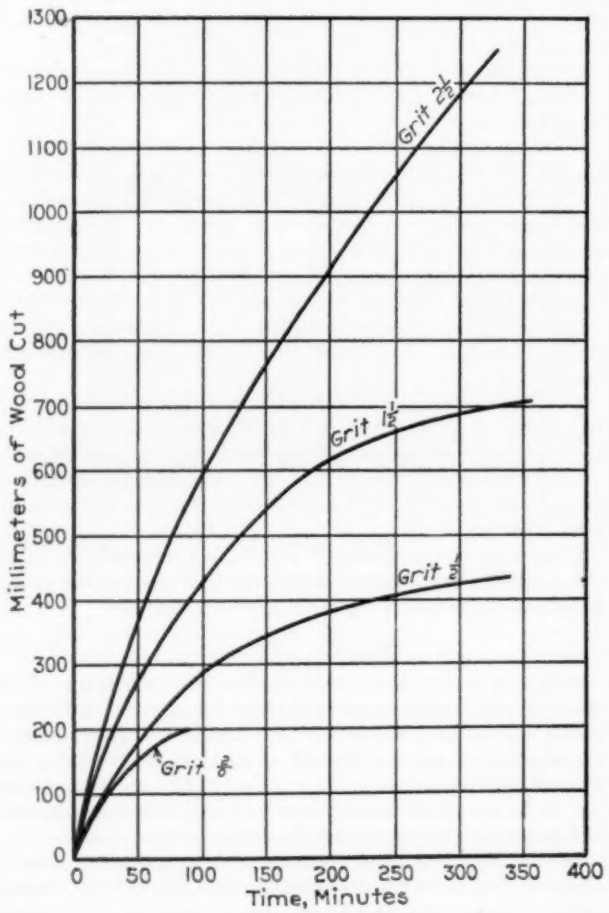

FIG. 7 BELT TEST CUTTING CURVES
(Amount of wood cut with different grits, using roll garnet paper.)

of results with those obtained in the field indicate that they represent good mediums for cutting determinations. Under controlled conditions in the testing laboratory, it is possible to get check results within a few per cent, and then almost without exception the results are substantiated in the field. Frequently, users of sandpaper are asked to conduct check tests of this kind, and their helpful assistance renders a great service, not only to the manufacturers of coated abrasives, but to all users as well.

BELT TESTERS

Two different types of belt tests have been used successfully which are described in detail for the benefit of any one who may wish to establish a belt-testing program.

(1) *Comparison With a Standard.* A Peerless belt-sanding machine, taking a sandpaper belt 4 in. wide by 86 in. long, is

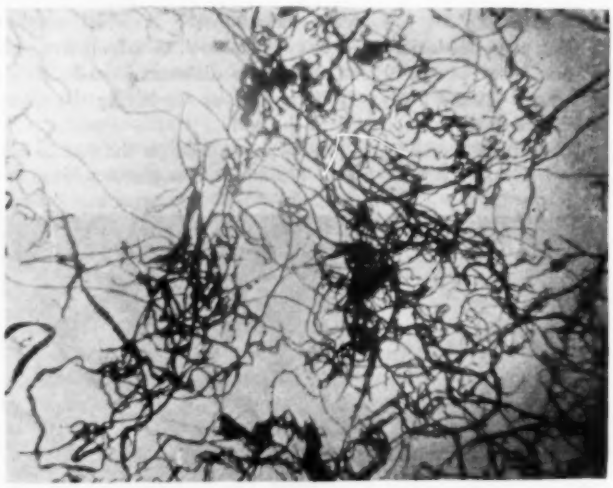

FIG. 8 WOOD ABRADED BY A FINE GRADE OF SANDPAPER
(The material removed is in the form of fine shavings, not sawdust.)

equipped with an arrangement for holding the wood test blocks to be abraded. The blocks may be counterbalanced so that any unit pressure within reasonable limits may be applied. For several years every run of woodworking material in the most generally used grits was tested by this method.

For a standard, a representative serial is selected and a good quantity put aside. It is not selected with the idea that it is 100 per cent, but rather as a reference mark.

Test blocks $1^1/_8$ in. wide, $^7/_8$ in. thick, and approximately $4^3/_4$ in. long are cut from well-seasoned oak boards. The length of the block ($4^3/_4$ in.) is determined by the travel of the block holders by which the blocks are applied to the belts and the economical width in which oak boards may be bought. The blocks from each board are placed in a separate container. Five blocks constitute a set, which is placed in a holder so that the ends of the blocks are applied to the belt and the sanding is done with the grain. These blocks are obtained by sawing $1^1/_8$ in. wide pieces off the end of a board $4^3/_4$ in. wide and $^7/_8$ in. thick, as shown in Fig. 5. One belt made from the standard material is tested on blocks from each container; that is, the standard is always tested once on each board.

Three tests (each one on a different path) are made on each belt. First, the belt is run 9 minutes. At the end of 9 minutes a new set of blocks is inserted. These are run 1 minute, and a reading in millimeters is taken. A millimeter scale and pointer are so arranged that the amount cut from the blocks being tested can be determined by taking a reading of the location of this pointer at the start and end of the test period. Five minutes later another reading is taken. The difference between these two readings represents the amount cut in millimeters in the interval between the 10- and 15-minute readings.

The blocks having been run 1 minute before the first reading is taken assures that the start of the test is always made under the same conditions. The result of the test is expressed in per cent of the amount cut by the standard, using blocks cut from the same board. This method helps to decrease any variation that might be caused by a variation in hardness of different boards.

A 5-minute test is used as a means of conserving the standard material. This test period, from the 10th to the 15th minute,

was chosen after extensive experiments had proved that this would give a reliable indication of what the material being tested would do during the average period of its commercial cutting life. It was found that the cutting curves rarely, if ever, crossed each other after this period within the economical life of the belt. A further method of conserving the standard material consists in using a set of blocks composed of one block each from five containers; that is, one block from five different boards. This also tends toward a more uniform test by modifying the effect of a board harder or softer than the rest.

A unit pressure of 16 oz. per sq. in. is used on the test blocks and a belt speed of 3000 lin. ft. per min. The test machines are

FIG. 9 WOOD ABRADED BY A COARSE GRADE OF SANDPAPER
(Showing that the cutting action is the same regardless of grade.)

arranged so that the unit pressure on the test blocks and the belt speed may be varied, but it has been determined, through a wide variation of belt speeds and pressures, that the greater the speed or pressure, or both, the faster the cut, there apparently being no critical speed or pressure that would give maximum cut.

Belt joints must be carefully made as a thick joint will cause the test blocks to jump and cause chattering that will affect the results. The successful operation of a belt testing machine depends to a large extent on the method of applying the test blocks. The use of a piece of sponge rubber back of the blocks will prevent chattering and vibration of the blocks and a consequent variation in the test results.

(2) *Direct Comparison Without a Standard.* This method of testing is more applicable to the comparison of several different runs or kinds of coated abrasives than to routine testing, although with some modifications it might be readily used for routine testing. One advantage of this method is the elimination of the standard and the possibility that the standard may change due to improper storage or other conditions.

For these tests a Peerless belt-sanding machine, taking a 4-in. by 48½-in. belt, is used. Fig. 6 shows this machine. The machine is enclosed in a small room in which the temperature and humidity are controlled. It is necessary to recirculate the air drawn out by the dust-removing fan, which is easily done by putting the dust-laden air through a bag filter, after which the air is returned to the test room. By proper manipulation of the heating unit and moisture spray, the temperature and humidity may be controlled within the required limits.

The belts and test blocks are conditioned at a constant temperature and humidity for 24 hours before being tested. This allows them to come to moisture-content equilibrium. A relative humidity of 35 to 40 per cent, with a temperature of 70 to 75 deg. fahr., is satisfactory for both conditioning and testing the belts.

A set of five oak blocks of the same size as used in the testing method previously described are used in the same type of holder. For this method, however, five blocks taken from five different boards are used to give a greater quantity of comparable wood. Great care is used to select uniform blocks; all those that have knots, hard places, or that appear soft are discarded. The selection of the blocks depends to a great extent on experience, but is quite reliable and susceptible of control.

Three tests are made in different paths on the same belt. Where possible, however, three belts are used, one test being made on each belt. The test is run from 30 to 90 minutes, depending on the grit. Readings in millimeters to determine the amount cut are taken every 5 minutes, and a cutting curve is plotted, time being plotted as abscissa and millimeters of wood cut as ordinates.

Oak has been chosen as a testing medium after experiments with a number of woods, including pine, mahogany, maple, bass, and gumwood.

A typical cutting curve is given in Fig. 7, showing the effect of a grain size or grade in removing material. The direct-comparison method was used in these tests. Oak test blocks, as described, were sanded under a pressure of 2 lb. per sq. in. This cutting curve was a part of a very extensive study of the cutting effect of various speeds and pressures. As stated before, it was found through quite a wide range of speeds and pressures that there was no critical speed or pressure, but that in general the greater the belt speed or unit pressure, or both, the more material was removed.

Two interesting microphotographs are shown in connection with the cutting action of coated abrasives on wood. The material removed is actually small shavings instead of sawdust, as is generally supposed. One, Fig. 8, shows shavings removed by a fine grit, while the other, Fig. 9, shows those removed by a coarse grit.

Except for the thickness of the shaving removed, the other characteristics are identical, indicating that the cutting action is the same regardless of the grade number of grit size.

RECIPROCAL TESTERS

A type of reciprocal tester is employed in the industry which is sometimes referred to as a grit retention or wear tester, consisting essentially of a machine for rubbing two pieces of sandpaper together under controlled conditions and weighing the amount of grain removed. Two pieces of the same size are dyed out of the sample of sandpaper to be tested, and these are conditioned overnight at a relative humidity of 65 per cent.

In running the test, one piece of paper is fastened to a table, abrasive side up, while the other is fastened to the rubbing block. The rubbing block is moved back and forth at a uniform velocity for 300 complete strokes, 50 complete strokes to the minute. At the conclusion of the test the loose abrasive particles are brushed on a watch glass and are weighed on an analytical balance to the nearest 5 milligrams.

This test is of value on grade No. 3/0 and coarser. The probable error is 8.8 per cent on samples taken side by side. The weight of the rubbing block is 10 lb.; area of contact on block, 4½ in. by 2 in.; length of stroke, 1 in.; speed of stroke, 50 per minute; number of strokes, 300, with uniform velocity.

The values obtained are expressed in milligrams. A test of 350 or less is considered satisfactory for most products. Certain products, such as metal cloth, which is designed for a high wear resistance, should test less than 175. In a few cases higher values are actually desirable.

The test reflects the quality and condition of the grain, the quality and condition of the adhesive, and the conditions of fabrication; that is, the construction of the coating. The test

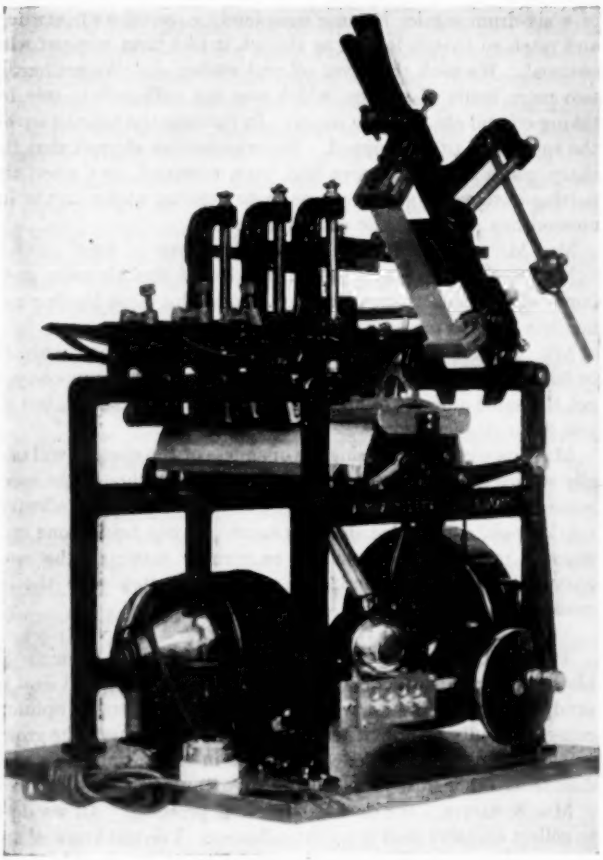

FIG. 10 WEAR TEST METER

is influenced by the amount of top-size adhesive employed, but within the normal top size range the test results are reliable.

The results of the grit-retention test bear a close relation to efficiency constants determined from belt-sander tests. Together they predict the amount of service that a sandpaper will perform.

Fig. 10 shows a wear-test meter which is manufactured commercially and used for testing textiles, leather, carpets, linoleums, etc., and which can be used to test coated abrasives. For testing sandpaper, a standard sheet is placed on the oscillating drum, and the samples to be tested can be stretched in the sample clamps. The amount of abrasive removed is again the measure of value. The illustration shows a four-arm machine, in which four samples can be tested simultaneously.

Reciprocal testing machines have also been employed in which a block or form covered with the sandpaper sample is caused to move backward and forward at a constant speed and pressure upon a piece of test material. The amount of stock abraded serves as the measure of cutting efficiency. Disk testing machines have been similarly employed in which the test piece to be sanded is fed to a revolving disk. Both of these methods have thus far proved more reliable in the testing of metal and composition and have not found much application on wood.

CONCLUSION

The development of standardization measures in the sandpaper industry has resulted in the general production of better coated abrasives which are uniform in specifications affecting interchangeability of competing products. Such specifications particularly refer to grit sizes and grade spacing, backing weights, coating tolerances, and color; and the purchaser, in addition to having reaped the benefits of quality improvement, can buy, without restriction as to individual manufacturer, on specifications as to these factors, which are probably more rigid than he would individually impose. He has only to concern himself with the selection of the product which will give most satisfaction in his particular application.

Industry standardization has been accompanied by the adoption of plant standards and refinement of operating control. The individual development among the different sandpaper manufacturers involving differences in the uses of materials, skill in manufacturing methods, accurate control of materials, research, and perfection of equipment has been such as to make for considerable variations between the working qualities of the product from one manufacturer and another, leaving a strong individuality of product in the industry. The refinement of quality control is designed to effect constant improvement and uniformity.

Factory testing mediums consisting essentially of belt, disk, and reciprocal testers provide a means of evaluating the cutting efficiency of the finished product.

Discussion

G. H. GOVE.[2] The great advances which have been made in the quality of coated abrasives during the past ten years can be attributed to a great extent to the greater use of technical control in this industry. As the author has indicated, the reduction in number of grades and backings has made it possible to concentrate the attention of the raw-material suppliers on the problems of higher grade materials of more uniform nature. The standardization of abrasive grades has clarified a most troublesome industrial problem, resulting in better service to consumers of coated abrasives.

This industry is one in which rapid advances in quality occur, caused primarily by better raw materials, better plant supervision, and better methods of testing the finished product.

We have found at this plant that the reduction in the number of items to be manufactured has increased quality and more particularly has increased our ability to give prompt delivery. Standardization of raw materials has increased the quality of the product. Technical control of plant process has assured uniform, high-grade products, with a constant improvement. The paper has covered these ideas in great detail and clearly shows how these standardizations and tests have been developed.

G. H. KOHL.[3] Conditions in a plant are sometimes such that a fair test is not always possible. In regard to tests, we are up against the fact continuously where an operator will feel better in the morning than he will in the afternoon, and therefore exert more pressure, or vice versa; and the result is that one never gets the same result from the sandpaper. That is one of the outstanding reasons why tests are not always fair. The conditions of the machine in the plant which is not operating to its best capacity will often affect the sandpaper. But we are anxious to hear from the men in the plants as to what way they think sandpaper should be tested in the plants.

J. A. MCKEAGE.[4] In an ordinary drum sander or belt sander,

[2] Superintendent, United States Sand Paper Co., Williamsport, Pa.

[3] Power Corporation, Montreal, Canada.

[4] McKeage Woodworking Machine Company, New York, N. Y.

is it in the testing machines that these various papers have been tried out? Is the cutting of any particular wood directly proportioned to the speed or not?

MR. SCHACHT. This is a question which a machine manufacturer always asks because he is very much interested in the speed of the machine and the amount of pressure applied. We attempt to find the answer on our factory testing equipment and in the field, where unfortunately the limitations of the machine often govern the results. On testing machines within safe working limits, we have found that the amount of wood abraded is directly proportional to the speed, pressure, and grit size. In field tests it was found that no increased cut was obtained in speeds beyond the 5000-ft.-per-min. mark. In regard to finish, I am a little hesitant to say what would be the result of increased speed and pressure, because finish cannot be evaluated on test blocks. Increasing speed and pressure will produce increased cut at least up to about the 4500 to 5000-ft.-per-min. range.

MR. MCKEAGE. Can you give the maximum speed recommended to sandpaper?

MR. SCHACHT. Four thousand feet per minute on garnet and 4500 ft. per min. on aluminum oxide seem to be maximum speed limits on woodworking operations as far as increased efficiency is concerned. These are general figures substantiated by laboratory tests and tests conducted in the field by manufacturers who have their plants equipped with direct current and could make observations as to square footages sanded with varying speeds.

M. J. MACDONALD.[5] Does that speed mean on all grains?

MR. SCHACHT. That represents some tests on intermediate grit numbers. I should like to ask some of the sandpaper people if their views coincide with mine.

MR. KOHL. I think the higher speed you have, the better finish you get.

J. C. DUKE.[6] I have had some experience in that field in running speeds and stepping up speeds. I think that Mr. Schacht has shown that in the control in the laboratory tests of sandpapers, the sandpapers have been increased in quality to the point where we are able to step up speeds. Some of the woodworking machines have run 3500 f.p.m. There are several well-known belt sanders that are today running 4300 and 4500 f.p.m. Some years ago that speed would have caused burning in panels. Sandpapers have become sharper in their manufacture. One particularly interesting case was that machines that were capable of standing greater speeds were being driven at a speed of 2500. This is a very slow speed. This was prolonged to a point where, perhaps, more heat was caused by the friction passing across the wood. In this particular instance, we stepped up the speed of the machine to 4000 f.p.m. At a speed of 4000, after marking the panels, the finish was pronounced far superior. The length of life of the product was increased by about 30 per cent. There have been several tests of this kind in plants, and in all cases the finish was much better and the length of the life of the product was a great deal better.

MR. MCKEAGE. In sanding varnished surfaces, of course all know that the paper fills up more rapidly. Is that due to the varnish or to the foreign material actually jamming in the grain of the sandpaper or is it due to the heat of the cutting? If you cut closer when you are cutting varnished floors, will that do away with the gumming of the paper to any extent?

MR. SCHACHT. Filling up is probably due to the dulling of the abrasive particles, causing heating which promotes loading with both the varnish and sawdust. If we take a piece of paper whose surface has been gummed up either through sanding varnish or sanding a resinous wood like pine, we find that if we clean the sheet and put it back on the drum we get very little additional service. I recall seeing a field test on pine where six hours was the average length of service before the cutting drum of a six-drum sander became completely covered with sawdust and pitch so that it looked as though it had been covered with oatmeal. We took the cover off and washed it. We got hardly two more hours of service, which was not sufficient to pay for taking off and cleaning the paper. In running the cleaned cover, the speed had to be dropped. An examination showed that the sharp edges of the abrasive had been removed, and when the cutting edge was gone there was more heating, and with the increased heating came the excessive loading.

MR. MCKEAGE. Is there a marked increase of heat?

MR. SCHACHT. When the little edge of the abrasive goes, increased heating is experienced, attended by rapid loading and finally a marked increase in temperature.

MR. MCKEAGE. If you use open coated paper with 50 or 60 per cent the amount of abrasive on the belt, I suppose you get the same amount of cutting by increasing the speed, but do you get a cleaner paper?

MR. SCHACHT. Increasing the openness of the coating will usually reduce the cutting capacity of the belt, even though the speed is increased on account of the reduction in the number of effective cutting points, provided that the sanding is not being done on a resinous material. On resinous or gummy material, the open coat will stay cleaner and give more production with the increased speed.

THOMAS D. PERRY.[7] In the salvaging of the dust through the blowpipe in the various factories, we accumulate a good deal of sandpaper dust and sand, which, according to the general opinion, causes difficulty on our grates and in many cases causes the grates to clog. Has any progress been made in separating sandpaper dust from other dust in woodworking manufacture?

MR. SCHACHT. We do not have that problem. All we do is to collect abrasive dust in a dust collector. I do not know of any way of segregating in the woodworking trade the dust from the abrasive material removed, and I do not know any way of reclaiming it.

MR. PERRY. The theory was advanced that there were certain formations coming from sandpaper dust that caused trouble on our grates.

MR. SCHACHT. I would question whether you get that proportion of sand to wood. I do not imagine in a day's running of a plant that you would get enough abrasive material to form anything on a grate.

MR. MCKEAGE. Which is the best buy, paper or cloth?

MR. SCHACHT. If it can be used, paper is the best. It is considerably cheaper and the coating is just as good on paper as it is on cloth. Therefore it will cut equally as well and often in tests it exceeds the production from cloth. Cloth is usually used where the limiting factor is flexibility. The cause of ultimate failure in most belts is not the rupture or failure of the backing, but instead the wearing out of the cutting surface. Paper is sometimes likely to be brittle if overdried in storage and then may crack and tear across if it is pinched, whereas cloth will stretch and accommodate itself. On a 6-in. belt there is quite a resistance to any strain. Paper is the best if one can use it, but where the conditions of service prevent its use, then combination or cloth should be selected.

P. H. BILHUBER.[8] When a board is sanded, snake marks occur. What are the results and what can be done to eliminate them?

[5] Long Island City, N. Y.

[6] Minnesota Mining & Mfg. Co., St. Paul, Minn.

[7] New Albany Veneering Company, New Albany, Ind.

[8] Steinway Piano Company, Long Island City, N. Y.

MR. SCHACHT. This is a problem which is always coming up. We find in some cases that no matter what paper is used, the snake marks will persist. Here we draw the inference that the fault lies in the machine and may be a condition of the drums, the felt covers, etc. By carefully removing the pitch and sawdust from the loaded spots on a snake-marked cover, we can attempt to find irregularities in the coated surface. It is practically always impossible for us to find one grain or series of grains which cause the snake mark, and calipers will show no differences in elevation greater than those present on other parts of the cover. In running hundreds of thousands of yards of paper with only infrequent snake-mark trouble, it is impossible definitely to place the blame on the sandpaper. I do not know what the abrasive manufacturer can do to eliminate snake marks beyond producing evenly distributed and level coatings. Are not snake marks generally noticeable on drum covers which have run their normal course of life?

MR. BILHUBER. In my opinion, it is not so much a case of the doctor as it is the nurse. There are certain reasons for the snaking on drum sanders. It is present in every drum sander that uses the oscillating drums. It is just the degree in which these snake marks occur which render them objectionable or not.

MR. MCKEAGE. One reason for the snake marks is that you have dried gears and they chatter, so that it affects the side oscillation, and causes marks like duck tracks, and this is also due to your felt getting too hard. The main thing is to get slower oscillation or else there is so much play in the mechanism that the proper effects cannot be secured.

MR. BILHUBER. The only kind of a machine to use in a plant is a good machine, and any that is older than six or seven years should be sold or given away.

MILTON KUBELL.[9] On my treatment on sanders, after 1200 or 1300 ft., I start getting snake marks. How would you account for that?

H. G. SEAMAN.[10] We find that as soon as the paper begins to wear down, the snake marks show up. The cause for this we found was that the rolls were not stationary while in operation.

ARTHUR SMITH, JR.[11] What were the main considerations which led the sandpaper makers to drop the double-faced finishing paper.

MR. SCHACHT. First, the demand for double-faced finishing paper dropped to a very low point. Secondly, the differences between single -and double-faced finishing papers are really very small. Double-faced paper consists of two plies that are easily separated in the middle, each ply being 30–32-lb. paper. Single-faced paper is made on 40-lb. paper, so the difference in paper weight is small. As far as the user is concerned, in buying two sheets of single-faced paper at approximately the same price as one sheet of double-faced paper, he gets a big bargain, because it is obvious that in making double-faced paper, we coat one side, run it through the whole drying process and then return it to be coated on the other side, which produces one sharp and one dull side. You probably would secure 100 per cent service from one side and hardly 75 per cent from the other. Double-faced paper is still available but it is not made as a standard item.

MR. SMITH. Our finishing foreman tells us that there is an advantage is using the double-faced paper double; that it permits the mechanic to get a better grip on the paper in holding it in his hand. Do you think that is so?

MR. SCHACHT. I am afraid that he would be wasting paper if he did it.

Improvements in Steels for Wood-Cutting Saws and Knives

HENRY B. ALLEN,[1] PHILADELPHIA, PA.

The important factors in a review of saw steels are the blade which carries the teeth and the teeth themselves. There is little in sight to promise further marked improvements in the solid-tooth type of saw. The next logical step is to use inserted teeth made from materials known to be well adapted to the function of cutting wood. The same forward step was taken years ago in metal cutting.

THE two important factors in a review of steels used for saws are the blade which carries the teeth and the teeth themselves. The steel for the blade, after heat treatment, should combine high elastic limit, good ductility, resistance to fatigue cracking, resistance to impact, and uniformity. There is little in sight to promise further marked improvements in the solid-tooth type of saw. The next logical step is to use inserted teeth made from materials known to be well adapted to the function of cutting wood. This same forward step was taken years ago in metal cutting. Future changes in design, so as to put to use metallurgical discoveries, will require the best thought of saw user, machine builder, and saw maker. Research and untiring effort alone lead the way to accomplishment.

The saw is a venerable tool. It dates back to prehistoric time. The first saw consisted of serrations along the thin edge of a piece of stone or bone. As bronze and, later, iron were discovered, the same scheme was followed, only with the greater refinements made possible by the malleability of the metals.

When steel came into civilization, still further improvements were possible. Here was a material which could not only be forged into shape, but subsequently could be made hard and springy.

It is interesting to note that at this stage of development Western practice very probably branched off from that of the East. The bronze or iron saw, because of its lack of springiness, could be used only to full advantage when pulled through the material being cut. The Oriental still operates his hand saws in this fashion. The West, however, finding that a tempered blade possessed enough spring to prevent buckling, decided to do his cutting on the push stroke.

Civilization has always been slow to change. This conservatism has applied with full force in the field of the mechanic arts. Great changes, however, are taking place in our day; the teachings of science are more widely accepted and applied than ever before. If a curve were plotted between time and the application of progressive ideas in the field of mechanics, we would see a long, slowly rising line, with here and there an up or down trend, until a comparatively few years ago, when the curve started up the present rapidly increasing slope.

The saw maker and user have, in the past, been no exceptions to the general law of human conservatism. The manufacture of saws has been an art acquired by years of first-hand experience. Specialized knowledge and equipment have been required. The manufacture has therefore been retained in the hands of comparatively few. Probably for these reasons there is a remarkable scarcity of published information about the steels used.

Simplicity is a consideration of prime importance in any device. The saw has been a good exponent of this principle. Even today the greater number are made from a single piece of steel, the blade and teeth integral and of the same temper. The advantage of this design is mainly simplicity of manufacture, hence low cost. The disadvantage is that the steel forming the blade must also serve for the teeth. The blade, as we shall see later, requires properties which do not coincide with those best suited to a cutting edge.

The obvious way to eliminate these shortcomings of the solid-tooth saw is to provide separate teeth which can be mechanically attached to the blade. Thus each part of the saw can be made out of a material best suited to its respective function. Inserted-tooth saws have been used to some extent for many years, although not primarily for the reason just stated. In the past they have found their place mainly because of the ease of keeping them in running order and also that they hold to their original diameter. More attention has been lately paid, however, to their great usefulness in providing the means of applying a more efficient cutting medium for the teeth. The discovery of new steels and materials which display valuable properties for cutting wood, but which cannot be used for the blade, must result in the further development of the inserted-tooth saw.

There are therefore two general types of saws, the solid tooth and the inserted tooth, to be included in a discussion of the steels used. Inasmuch as the problems of today are concerned mostly with power-operated tools, the paper will be confined to that type.

There are two equally important factors which must be considered in a review of steels used for saws; namely, the blade which carries the teeth, and the teeth themselves. Both are of equal importance to the success of the saw. The subject of saw steels will therefore be taken up under the two headings. Knives also can be treated in the same way, although the problems offered by the knife back or blade, as distinct from the cutting edge, do not offer the same difficulty.

The Blade

Most tools can be made with as heavy a shank or body as is necessary for rigidly supporting the cutting edge. The saw, however, is an exception. By its very nature it is a thin tool. The policy of conservation in the wood industries is increasing the tendency toward greater thinness. While the saw blade has strength and rigidity in a direction truly normal to its thickness, it is weak and flexible under side strain. The rigidity of a saw has a direct bearing on the accuracy and smoothness of the cut produced and on the rate of cutting, which are considerations

---

[1] Chief Metallurgist, Henry Disston & Sons.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

of first importance. An increase in the blade thickness is the direct way to produce greater stiffness, but this method is prohibited by the equally important consideration of wood wasted. A material having a higher modulus of elasticity would give greater stiffness to bending, but there is no relief in sight. We have to be content with the 29,000,000 elastic modulus of steel.

The speed of a revolving circular saw and the static tension applied to a band saw furnish a stiffening effect which compensates in part for the flexibility of the disk or band.

A circular saw revolving at wood-cutting speeds involves the complicated mechanics of centrifugal stresses and also vibrations. The stresses set up by centrifugal force are low as compared with the strength of steel. A 16-in. saw revolving at 3600 r.p.m. has a maximum stress from centrifugal force of about 6000 lb. per sq. in., and this occurs at the center hole. But while this stress is not high, it does produce some stretch in the blade, which is not uniform from center to rim. These strains in turn, if uncompensated, result not only in added lack of stiffness, but even in an actual fluttering of the rim.

To counteract the stretching from centrifugal force, the circular saw blade is given a prestraining operation called tensioning. This may be done by hammering, rolling, or otherwise, and results in a saw which will be "stiff" when up to speed. The stretching of the saw rim in work due to frictional heat is compensated for in the same manner. While the stresses set up by centrifugal forces are low, those induced by the prestraining treatment are high.

The steel for the blade, after heat treatment, should combine: (1) High elastic limit, (2) good ductility, (3) resistance to fatigue cracking, (4) resistance to impact, and (5) uniformity. And because most saws in use today are of the solid-tooth variety, there is an additional qualification; namely, (6) satisfactory edge holding.

It is self-evident that the steel and its fabrication into saws must not be too costly. Another consideration that is becoming increasingly important is that the steel weld readily.

(1) *High Elastic Limit.* The saw blade should behave as nearly as possible as a perfect spring. Operating strains, due to centrifugal force, frictional heating, or other normal causes, should produce as little permanent distortion as possible. If a blade is strained beyond the elastic limit, it will be stretched or distorted, and the saw will have lost its tension or have become uneven and lumpy. In any event, it will not run true, and so will produce a poor cut and not stand up under heavy feed.

Plain carbon-tool steel, formerly used for all saws, could not be heat treated to the high elastic limits found desirable for the more modern production rates without an over-sacrifice of other essential properties. For instance, a high elastic limit would be accompanied by brittleness. The usual carbon content of the steels used was 0.85 per cent, although it might range as low as 0.70 per cent up to 1.10 per cent. The carbon content used depended more on the edge-holding requirements of the teeth, although high carbon was often selected for a thick plate so as to get better hardening.

Nickel was the first alloy used to any extent in saw steel. The object was to produce a stronger blade without sacrificing toughness. The nickel content ranged between 1.25 to 3.5 per cent, with carbon between 0.60 and 1.00 per cent, depending on the use of the saw. The plain nickel steel constituted a real advance in saw steels, and it is still used to some extent. One objection to this steel is its tendency toward a striated, crystalline structure which may result in spalling teeth. Another difficulty encountered in the use of this steel is sluggishness in tempering, some of the hardened steel structure remaining, with consequent brittleness. These objections are more often met with when the nickel and carbon contents are on the high side. However, when on the low side the amount of benefit derived is open to question. The compositions shown in Table 1, (*a*), (*b*), and (*e*), are types still used to some extent.

The properties of nickel steels were so interesting that the next developments of alloy saw steels were mostly made with the view of eliminating its weak points by the use of one or more additional alloys. Following other alloy-steel developments, chromium was tried and found to give very high elastic limits, but at some sacrifice in ductility. The steel showed a tendency to be "brash," as the old sawmaker calls it when the steel will not stand considerable cold swaging without checking. Vanadium was added with the object of overcoming this "brash" condition, but without more than a partial cure. It does, however, produce a marked increase in toughness. Nickel-chrome steels are used today for many saws where the ductility requirements are not severe. Typical compositions are shown in Table 1, (*c*), (*d*), (*f*), and (*j*). Chromium is an inexpensive alloy and in some compositions can be obtained from the scrap metal charged into the steel melting furnace. Chromium, too, in small amounts, enhances the hardening power of nickel steels and so aids the saw manufacturer in hardening the thicker saws.

Another attempt to obtain high strength, together with high values for the other essential properties, has resulted in nickel-molybdenum steels, both elements being present in small amounts. Table 1 (*g*) shows a typical composition used very largely and with good results. The elastic limit can be made high without sacrificing ductility and toughness. The types shown under (*j*) and (*k*) are very good steels where no cutting edge is involved.

(2) *Ductility.* The elastic properties of steel, together with its ductility, make possible the tensioning or prestraining treatment essential to a band or circular saw. Mechanical tensioning is done by hammering or cold-rolling selected areas of the saw. The cold working elastically expands the steel adjacent to the spots where the force is applied, the latter spots being permanently stretched. A steel low in ductility can be given but little deformation by the cold working without dangerously approaching the breaking point.

A phase of ductility, the ability to be cold-worked without rupture, is an essential property of solid-tooth saws whose teeth are swaged for clearance.

The property of ductility is dependent, to a large degree, upon the inherent quality of the steel as determined by the method of manufacture and the quality of raw materials used. No alloy will compensate for inferior steel-melting practice.

As noted previously, chromium does not assist in developing ductility in saw steel. Nickel does help, and the combination with molybdenum, Table 1, (*g*), gives particularly good ductility with high elastic limit. Alloy steels have eliminated most of the body cracks which were fairly common in carbon-steel saws.

(3) *Resistance to Fatigue Cracking.* The high speeds and feeds at which production saws are now run have introduced new problems. Among these is the matter of gullet cracking, due to repeated stress below the elastic limit of the steel. Cracks of this type can usually be identified by the lines of progressive growth on the adjacent surfaces of the fracture. Sharp angles or corners should never be allowed where there is repeated stress, but the saw user often allows this condition to exist. Gullet cracks sometimes occur which cannot be traced to any such self-evident cause. Those who have made extensive studies of the phenomenon of fatigue cracking are generally agreed that the strength of steel to resist this type of failure bears a direct relationship to the ultimate strength; also that the freedom of the steel from dirt and other inclusions has a direct bearing on its resistance. If such is the case with saws, the present-day alloy steels, when clean and well made, should possess remark-

able resistance. This is not always true, and there is reason to believe that fatigue cracks in band and circular saws may be caused by complicated stresses which are aggravated rather than relieved by high physical properties. Good ductility in the steel is a valuable asset, however.

Special measures can be used to largely prevent fatigue cracks from forming. Properly designed and spaced rim slots is one means often used. Another method frequently practiced, in band-saw mills, is to cold-work the bottoms of the gullets, thus stretching the metal at those points. Keeping the saw sharp and preserving well-rounded gullets and even tension are self-evident and worth-while precautions.

(4) *Resistance to Impact.* A saw in service is subjected to repeated blows. If the teeth are sharp and the saw is in good shape, the normal impacts of the teeth in the wood are not excessive. But other shocks incidental or accidental to service may be heavy. One form of accident often met with is striking a piece of steel in the cut. The old-type carbon-steel saw would be apt to crack under such treatment, or at least be put badly out of shape. A good alloy-steel saw will either cut through the steel or will have teeth sheared off, the blade itself being left in fair condition. Side shocks which would distort a low-elastic-limit carbon saw will have little effect on the alloy blade.

(5) *Uniformity.* A saw which has not uniform physical properties will never be a satisfactory tool. If the blade has hard or soft spots, it can only be made flat with difficulty, it cannot be tensioned evenly, and it will not retain its trueness or tension in service. Lack of uniformity can be due to variations in steel composition or to faulty heat treatment. The first-mentioned cause is most apt to occur from failure to remove any decarbonized skin that may have been on the steel sheet. Faulty heat treatment is the usual reason for ununiformity and may result from poor heat-treating practice or by reason that the steel composition is unsuited to good hardening.

On account of the physical dimensions, saws must be hardened in a comparatively slow quenching medium such as oil. Carbon steels will not harden thoroughly in oil unless the piece is thin or unless it has been overheated, which is of course bad practice. Carbon steels, therefore, cannot be considered as suitable for saws to meet present high standards unless they are of light gage.

The judicious use of small amounts of alloy will give the steel suitable hardening properties. For this reason many saws that are to be used only for work of the lighter sort are made from low-priced alloy steels. Chromium is an alloy often used in this way, such as the composition shown in Table 1, (*h*). Where a slightly tougher steel is wanted composition (*i*) is a good choice.

TABLE 1 TYPICAL CIRCULAR SAW-BLADE AND BAND-SAW STEEL COMPOSITIONS

	Carbon	Nickel	Chrome	Vanadium	Molybdenum
(*a*)	0.70 to 0.90	2.00	..	..	..
(*b*)	0.70 to 0.90	1.25	..	..	..
(*c*)	0.70 to 0.90	1.25	0.25	..	..
(*d*)	0.70 to 0.90	1.25	0.35	0.20	..
(*e*)	0.70 to 0.90	0.70	..	..	..
(*f*)	0.70 to 0.90	0.70	0.25	..	..
(*g*)	0.70 to 0.90	0.70	..	..	0.15
(*h*)	0.70 to 0.90	..	0.40	..	..
(*i*)	0.70 to 0.90	..	0.40	0.15	..
(*j*)	0.55 to 0.65	1.25	0.35	0.20	..
(*k*)	0.45 to 0.55	..	0.80	..	0.20

Little need be said about the properties of the steel back in machine knives. Sufficient toughness is of course necessary, together with stiffness. Some types of knives, such as the hog and chipper, are subject to heavy impacts and pressures, and therefore the steel must possess more toughness than is needed for other kinds. The planer or finishing knife, on the other hand, will have sufficient strength if made out of a less tough material such as high-speed steel. Some typical compositions of solid knives are given in Table 2.

0.65	..	4.00	18.00	1.00
1.25	..	4.00	9.00	..

The Cutting Edge

The cutting action of a saw and of most knives is similar to that of other cutting tools. The wood is parted by a wedging action, and the power required is therefore a function of the cohesive strength of the material. When the wood is gummy, an additional factor of increased friction is introduced. No variety of wood is very strong as compared with metals, and therefore wood is said to be easy to cut.

There is, however, another and more vital factor than strength that enters into the cutting of wood, namely, abrasion. Comparatively little power is required to sever the fibers of any wood while the tool is sharp. The condition may be short-lived, however. The abrasive action starts at once to polish away the keen edge until, sooner or later, dullness results, enough to cause poor cutting and excessive power consumption. The saw maker and user have not sufficiently appreciated the relation between sharpness and smoothness of cut. A saw tooth is ordinarily considered sharp if it appears so to the naked eye, as it is left by a file or medium-grit abrasive wheel.

The abrasiveness of different woods varies very widely, even though their other properties may not be greatly different. An example of this difference is given by the test results shown in Table 3. The test was made with a 9-in. circular saw, electrically driven and with a positive feed, the wood being rip-cut.

TABLE 3

Kind of wood	Tensile strength, lb. per sq. in.	Power, in kw. Start	Power, in kw. Finish	Amount cut, ft.	Sharpness at finish
Maple 1 in. dry	19,100	0.70	0.78	426	Sharp
Bapepa 3/4 in. [a]	17,500	0.70	1.50[b]	27	Very dull
White pine 3/4 in.	10,000	0.55	0.45	766	Very sharp

[a] A South American wood, resembling mahogany.
[b] Over 1.5. The kilowatt-meter needle was off the scale and the motor stalling.

Abrasion is a complicated phenomenon about which little is really known. The type of abrasion met with in wood cutting can be pictured as a buffing action, the abrasive being cellulose and mineral salts, including silica. To make a particular steel more resistant to abrasion, the first thought would be to make the tool harder. But here enters one of the curious features about abrasion, at least under conditions met with in wood cutting. When the saw speed is very low, as in hand operations, greater saw hardness may result in increasing by several times the life of the edge. When the saw speed is high, however, as with a power tool, there is little difference in life between the harder and the softer tool. To obtain a marked improvement in edge-holding with fast-running tools it is necessary to change the steel composition.

The difference in tool life with change in tool speed and tool hardness, but with the same composition steel, is shown in Table 4. Although the material cut was a wood substitute, the comparison will hold for wood. The saws were made of 0.90 carbon-tool steel.

TABLE 4

Saw hardness, Rockwell (C)	Material sawed to dullness: Saw speed 150 f.p.m.	Material sawed to dullness: Saw speed 6000 f.p.m.
48 (filable)	In 8 ft.	In 5 ft.
62 (file hard)	In 36 ft.	In 6 ft.

It will be noted that at low speeds the increased life brought

about by the greater hardness was 350 per cent, whereas at high speed the increase was only 20 per cent.

Another example of the effect of tool hardness on the edge-holding properties is shown in Table 5. The tool was a knife used in an automatic handle-turning lathe and made from 0.60 carbon-tool steel. The wood cut was maple, finishing $1^1/_4$ in. in diameter. The speed was 3200 r.p.m.

TABLE 5

Hardness Rockwell (C)	Number of handles per grind
61–62	366
53–55	330
48–50	306
44–46	300

It is interesting to compare the results shown in Table 5 with those of Table 4. The increase of 12 to 14 points in Rockwell hardness between the 48 and the 62 hardness tools resulted in both cases in an increased tool life of 20 per cent. It is seen from Table 5 that the extreme difference in tool hardness between the hardest, which was tempered at 350 deg. fahr. and file hard, and the softest, which was tempered at 900 deg. fahr. and easily filed, resulted in a difference in tool life of only 22 per cent.

The effect of changing the composition of the steel is shown in Table 6. The tools were operating on the same job as that illustrated in Table 5, except that the wood cut was cherry. Their compositions are shown in Table 7.

TABLE 6

Steel	Hardness Rockwell (C)	Number of pieces per grind	Increased life over (*a*), per cent
(*a*)	61–62	276	
(*b*)	61–62	504	82
(*c*)	61–62	552	100
(*d*)	61–62	480	73
(*e*)	61–62	480	73
(*f*)	62–63	1020	270

It will be seen from Table 6 that the increase of carbon content, the hardness being the same, in the plain carbon steels (*a*), (*b*), and (*c*) resulted in a consistent increase in tool life, up to 100 per cent. Also that the medium-nickel–low-chromium-vanadium steel (*d*) gave about the same results as did the plain carbon steel (*b*) of like carbon content. The fact that the low-nickel–low-molybdenum steel (*e*) with comparatively low carbon, 0.76 per cent, had the same life as the higher carbon steel (*d*) is interesting. It would indicate that a steel of greater toughness, resulting from the lower carbon, can be had with no sacrifice in cutting life. The high-speed steel tool (*f*) had an unusually low life for this kind of steel, most saw and knife applications showing about a 10 to 1 ratio in its favor as compared with carbon-tool steel.

A significant point indicated by the foregoing tests is the far greater effect produced by a difference in carbon, as shown in Table 6, than by a difference in hardness, as reported in Table 5. The difference in hardness between high and low temper gave only a 22 per cent variation in tool life, whereas difference in carbon between high and low gave 100 per cent.

TABLE 7

Steel	Composition							
	C	Mn	Si	Ni	Cr	V	Wo	Mo
(*a*)	0.60	0.53	..	..	..	..	...	..
(*b*)	0.99	0.36	..	..	..	..	...	..
(*c*)	1.13	0.34	..	..	..	..	...	..
(*d*)	0.93	0.33	0.21	1.35	0.36	0.21	...	..
(*e*)	0.76	0.34	0.22	0.68	..	..	...	0.14
(*f*)	0.66	0.31	0.20	..	3.98	1.05	18.15	..

It must be borne in mind that the conditions under which the saw or knife is operating may have a marked influence on the comparative performance of different steels. In certain applications a carbon or low-alloy tool steel will give no service. Where the temperature developed in cutting is really high, only a material (as high-speed steel, for example) which remains hard at these temperatures will do the work. For some classes of work a steel having a tungsten content of from 2 to 8 per cent will give better service than without the addition, although not so good results as will high-speed steel. It can be taken as axiomatic that the better a steel resists softening at elevated temperatures and also the type of abrasive wear met with in wood cutting, the better service it will give.

We can make use of the improved properties of the steels in either of two ways: to obtain longer tool life under the same conditions of operation, or to maintain the same tool life but at a substantially higher rate of production. In either case, to effect a major change in tool performance, our present-day steels all fall into either one of two classes, high-speed steels and all other tool steels.

For wood as well as for metal cutting, high-speed steel is the best type known today. It is enough superior to warrant wider application to wood sawing than is now the case. The wood-working industry should profit more from the example set by the metal-working industry and establish, by fundamental research, more data about cutting its product. If the results of such studies were at hand, we would not only be making more use of the best steels we now possess, but we also would be better prepared for new developments in tool materials.

The recently developed cemented tungsten-carbide tool material will effect profound changes in wood cutting. It possesses toughness, together with hardness and resistance to abrasion, such that cutting speeds and quality of cut heretofore impossible will be obtained. A typical example of the results being obtained with this material operating on a machine designed for high-speed steel tools is given in Table 8. The job was planning, tonguing, and grooving fireproofed oak flooring. The 10-in. cutter head was operating at a speed of 3600 r.p.m. with a feed of 80 f.p.m.

TABLE 8

Knife material	Production per grind, feet	Increase, per cent
High-speed steel	400	
"Carboloy"	20,000	4900

Other applications of cemented tungsten-carbide knives and also saws are giving results similar to those indicated. The possibilities of such new materials cannot be ignored and can hardly be overestimated by the wood-cutting industry.

Conclusions

To one who has been in close touch with the recent developments of saw steels there is little in sight to promise further marked improvements in the solid-tooth type of saw. The two conflicting requirements for the one steel for the blade and for the cutting edge would seem to take us for further advances beyond the nature of this metal.

Up to 15 years ago, or thereabouts, the saw maker for a hundred years had spent an unbelievable amount of effort and ingenuity in effecting the best compromise possible with carbon steels. The next step was the development of an alloy-steel saw, with the object of producing a stronger blade and also to effect all possible improvement in edge holding. A much better blade resulted, but even with the aid of modern laboratories and metallurgical knowledge, there was little improvement in edge-holding properties, far from keeping pace with the potentialities of the new blade.

The next logical step is therefore to depart from the old-type saw and use inserted teeth made from materials known to be well adapted for the function of cutting wood. In the field of metal cutting this same step forward was made years ago.

Future changes in saw design, so as to put to use metallurgical discoveries, will require the best thought of saw user, ma-

chine builder, and saw maker. Research and untiring effort form the only road today to accomplishment, but the benefits in store for the woodworking industry are worth the struggle.

ACKNOWLEDGMENT

The author expresses his appreciation and thanks to Mr. S. Horace Disston, Vice-President, Henry Disston & Sons, Inc., for suggestions which have been most helpful in the preparation of this paper.

Discussion

J. P. POTTER.[2] Most of the experience that the writer has had in the woodworking field has been with saws and cutters. He has seen it pass from the old carbon steel to the high-tungsten steels and come on through to the cemented tungsten-carbide steel. A great many woodworking tools are made today without due regard to the safety of the swinging of steel and knives and saws, especially of the high frequency machine. When you go up to the neighborhood of 7200 to 9000, the centrifugal strains become very great. So far as is known, there has not been anything put on the market that offers absolute safety. The internal head or the solid-back head which was invented some 20 years ago comes the nearest to it, but it will not support a cutter projecting more than three-quarters or one inch.

Speaking primarily about saws, the prepared paper seems to be a very elaborate proposition. It needs very little addition.

The things noticed in practice regarding saws are the extreme misunderstanding on the part of those using the steel in knowing what strengths are required from it.

The matter of preparing steel for the shop is a subject which needs a lot of discussion. The stock patterns can be prepared in manufacturing plants far distant and remote from the point of manufacture and can be shipped in due time for ordinary purposes.

In plans for individuals, oftentimes one little house requires enough steel to write off the cost of the manufacture. The use of cemented tungsten-carbide steel is also costly. The writer has found that on stock runs the steel costs relatively little in proportion to the amount of wood run. It will range somewhere from 2 to 4 cents per 1000 ft. On an ordinary mold of 3 in. width, it will run with about 5 or 6 in. of steel with a 6-knife equipment all around. Those 60 in. of steel will run about 4,000,000 lineal feet of molding before they are completely worn out. That has been proved in soft woods along the Pacific Coast.

With the higher priced steel, it becomes a question. By the per cent of this paper, the steel will run so much longer than the ordinary carbon-tool steel that perhaps there would be no limit to the wear of the cuts. That brings up another problem of using this steel properly supported in very thin sections.

[2] American Woodworking Company, New York, N. Y.

AUTHOR'S CLOSURE

The points brought out by Mr. Potter are of real practical interest. The present-day use of saws and knives at higher speeds is no exception to the modern trend, and, as Mr. Potter indicates, the necessary safety precautions must be taken, not only in the design of the tool, but also in its use. A point in this connection may well be discussed briefly. An inserted-tooth saw or cutter head is usually refitted many times by the user. He must see to it that the blade or head is not only properly refitted, but also that it is maintained in good mechanical condition and balance. With higher speeds, the machine also must be kept in better shape than formerly was necessary.

In calculating the effect of centrifugal forces in rapidly revolving saws and knives, the subject should be considered from two angles. A revolving disk will have maximum stresses from centrifugal forces set up, not at the rim, but at the center hole. The stresses at the rim will be comparatively small. For example, a 16-in. blade with a 1-in. center hole revolving at 3600 r.p.m. will have stresses set up amounting to about 6000 lb. per sq. in. at the center hole and 1500 lb. per sq. in. at the rim. A 10-in. disk running at 7200 r.p.m. will result in about 9000 and 2000 lb. per sq. in. at the center and rim, respectively. These stresses are well within the factor of safety for a good steel and in themselves far from dangerous. Excessive rim strains set up by poor tooth or cutter-edge clamping methods vibrations, and accidental strains in operation are far more dangerous than those from centrifugal forces. The added danger from centrifugal forces as speeds increase does not come about as much through the greater possibility of a well-made and properly operated tool being broken by these forces as by reason of the much greater damage done if breakage occurs. The energy of a piece flying off the rim of a saw or cutter increases as the square of the r.p.m. of the tool. Thus doubling the speed of the rim increases the energy by four times, and protective measures must be bettered correspondingly.

Mr. Potter properly raises the question of economy in using expensive steels or tool materials for working ordinary woods. The relative tool costs must always be considered. An extreme case where a cheap steel is clearly good enough is where short runs of special molding shapes are made from soft wood with no particular requirement for surface finish. It would be poor economy to make an expensive tool only to discard it after a few hours' run. Special material like cemented tungsten carbide for woodworking is finding its first applications to production jobs where the wood is particularly abrasive and where machine down time or other factors are important. Users are, however, beginning to see its possibilities for more of their regular production work on common woods where accuracy or smooth finish is desired. Its use will grow as experience indicates its proper applications.

Need of Forest-Products Engineers in the Woodworking Industries

By NELSON C. BROWN[1] and RAYMOND J. HOYLE,[2] SYRACUSE, N. Y.

For many years it was thought that a forester had to do only with the growing and handling of the forest crop. Now the forest schools recognize that the utilization of wood products, including the conditioning, remanufacturing and merchandising of various forms, is just as important a part of forestry. To meet this situation, the curricula of some of the forest schools are changing. The woodworking industries have problems that need solution. Trained men who know about the technological features of wood are needed. In some way the forest schools have failed to train men to meet the demand in these wood-using industries. It is also felt that the industries have failed to cooperate with the schools in order to have the courses fit in with their needs. Closer relationship, however, is growing up between the industries and the forest schools.

Nelson C. Brown

Raymond J. Hoyle

As a general thing the woodworking industries are not showing as much progress as many of the other important industries. Their machines, methods, conditions of raw material, cost systems, and merchandising as a rule are years, if not decades, behind those of many well-known industries. The mortality among these woodworking industries is very heavy and will continue so until men who are especially trained for this field of work are sought by these industries. At this point it is fair to say that there are some industries in the woodworking field that are up-to-date, and their example should be followed.

Wood Industries Lack Trained Men

Why is it that men have not been trained for the woodworking industries? The answer is, that the schools where these men might be prepared have not realized that there was a field for such training, and the industries that need these men have apparently believed for the most part that years of experience in the industry was the most desirable kind of preparation. The reason why wood-using industries have not shown more progress can be laid at the doors of the industry as well as of the schools of higher education.

Educational Facilities Lacking for Most Engineers

Men trained in schools of engineering and schools of forestry are found in this industry, but the number is comparatively small, and their training has not been well suited to the work involved. Engineering schools have given practically no thought to the subject of wood—its growth, structure, manufacture, distribution, and remanufacture, conditioning, and use. Some forestry schools, on the contrary, offer considerable training in these various fields of wood. Wood, unlike many other materials, is not a man-made or controlled product, and consequently no two pieces are exactly alike, even though cut from the same position within the same tree. In fact, two such pieces are often dissimilar in many respects. When it also is considered that there are over one-hundred commercial woods in this country, one can realize why it is essential for a man to have considerable training in the field of wood if he is going to solve the many problems in connection with its manufacture and use.

Broadening Scope of Forestry

The wood-using industries as a rule have not sought the graduates of forestry schools, for they were of the opinion that these men were trained to grow and manage timberlands. The forestry schools years ago were concerned primarily in training men for handling the forests, and a few schools still cling to this idea, but some schools are today training men for other phases of forestry. Forestry is a young and growing profession and frequently sees new branches of the work and new fields of specialization. Forestry is such a very large field that one cannot expect to be trained for more than one of its branches. As the engineer must be trained in the chemical, mechanical, electrical, civil, or other separate branches so must the forester be trained in one of the several distinct branches of forestry.

It is unfortunate, in a way, that the public has come to think that forestry schools are training men only for the one field, viz., timber growing and managing, because when a forestry graduate applies to a wood-using industry for a job, the student is generally regarded as one who is prepared only for woods work. If the

[1] Acting Dean, New York State College of Forestry. Mr. Brown received his B.A. and M.A. from Yale. His background of experience includes U. S. Forest Service, 1908–1911; Professor in charge of Forest Utilization, New York State College of Forestry, 1912–1917 and 1921–1930; U. S. Trade Commissioner in Europe, 1917–1918; Adviser to Czecho-Slovak Republic on forest management; partner and manager of the American Woods Export Association, and member of the New York State Reforestation Commission. He is the author of "Forest Products, Their Manufacture and Use," 1919; "The Lumber Market in Italy, Spain, and Portugal," 1919–1920; "The American Lumber Industry," 1923; co-author of "Elements of Forestry," 1914. Mr. Brown has contributed many articles on various phases of the lumber industry.

[2] Professor of Forest Utilization, New York State College of Forestry. Mr. Hoyle received his B.S. from the New York State College of Forestry at Syracuse in 1917 and M.S. in Economics from Syracuse University in 1930. He has been a member of the New York State College of Forestry faculty since 1918. Mr. Hoyle is author of the following college publications: "Wood Using Industries of New York," 1921 and 1928; "The Manufacture and Use of Small Dimension Stock," 1927. During vacation periods he has been connected with the U. S. Forest Service, Hammond Lumber Co. of California, U. S. Forest Products Laboratory, National Committee on Wood Utilization, and the West Coast Lumbermen's Association. Mr. Hoyle has contributed various articles to trade journals on the subjects of marketing, uses of wood, and improved practices in the lumber and woodworking industries.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

forestry schools that train men for the wood-using industries gave these men an engineering degree and called them "wood engineers" or some other name that would indicate to a prospective employer something of the nature of their training, it would be much easier for them to get jobs and to be properly placed in the industry.

Utilization of Forest Products

There are so many phases of the utilization side of forestry alone that the forest schools have found difficulty in choosing the various courses that would adequately prepare men for these several fields in four years. Logging, lumber manufacture, merchandising, remanufacture, conditioning of wood, and pulp and paper manufacture are all distinct fields for specialization. The wood-using industries (the field about which this paper primarily is concerned) is no doubt the largest of these divisions and should afford the greatest single outlet for graduates specializing in the consumption phase of forestry. If a student definitely knows that he wants to become, for example, a logging engineer or a sawmill manager, his courses should be chosen accordingly. Since most students do not know what special field they want to enter, emphasis should naturally be laid on the largest field. As yet the several fields of work for the most part are not clearly defined nor is there much assurance that the industry will afford a job in these several fields. Until the industry calls for men of a definite training, the schools will have to prepare men along rather broad general lines.

Experience at Syracuse

The New York State College of Forestry at Syracuse has recognized a need for men especially trained for the utilization side of forestry. Since its inception this school has offered courses designed to prepare men for this field. Several times in the past 15 years the school has added new courses or changed old ones to meet the changing demands of the lumber industry and to meet new developments and tendencies. At the present time those students who feel that they want to enter some phase of wood utilization spend the first two years in studying English, modern languages, mathematics, botany, chemistry, physics, zoology, entomology, drafting, dendrology, plane surveying, and timber estimating. (These same courses are also taken by nearly all students preparing for any phase of forestry, since they are fundamental and of a more general nature.) The third and fourth years are spent in specializing. The courses taken in the third year include one semester of elementary accounting, one year of economics, one semester of technical and report writing and business correspondence, one semester of history of forestry, one year of silviculture including the foundation work and forest propagation, one semester of logging and one of lumber manufacture, one semester of forest products other than lumber, one semester of wood structure and identification, and one semester of railroad transportation. Courses taken the fourth year include one semester of forest pathology, timber physics, business law, public speaking, portable milling and woodlot logging, lumber salesmanship, business methods, new developments and problems of the lumber industry, the economics of production, distribution and consumption of lumber, and one year each of wood preservation and dry kiln engineering. If a student is quite certain of the field of work he hopes to enter, he is allowed to substitute four courses in engineering, business economics, forestry, or science for certain specified courses in the fourth year.

Educational Courses Require Balance

If these courses have been noted carefully, it will be seen that the student has not only received good fundamental training in many basic subjects, but also has been given a somewhat specialized training for the problems and work of the lumber industry. He will understand the growth and behavior of trees and the economic and technical problems of manufacture and use. He will know the technical, physical, and mechanical properties of woods and why these woods can or cannot be used for some purposes in certain markets. The student has an understanding of the conditions, problems, and costs involved in converting a forest into lumber or other forest products, and the problems of merchandising, remanufacturing, and using this lumber in distant markets. An experimental dry kiln affords opportunity of practical kiln operation where the student learns in a one-year course of the actual practice as well as the theory and problems involved. Another year's course of study and actual operation of the experimental wood-preservation plant gives the student specific training for a definite field of work. If desired, additional courses may be taken in chemistry or pathology to supplement or round out his training in the preservation field. In fact, the student, because of the opportunity of electing several different courses, can take work that will give extra training for any one of the several fields of work. Courses elected in business and economics give a background and insight into these two phases of the industry, while courses in engineering are of benefit particularly to one who enters the wood-using industry field.

Practical Application

At the end of the second year, three months are spent in a camp in the woods where the classroom theory is applied and practiced. This practical application and the long hours of work are of great value. At the end of the third year, the student is given five months' vacation and encouraged to get a job in a mill, wood-using industry, wood-preservation plant, a retail yard, or in some phase of the lumber industry where he will get practical experience. During the senior year an especially arranged trip is taken to some place in the South where pine and hardwood logging operations are studied in detail and under supervision, and where other phases of the lumber industry are also incidentally visited and studied.

Industrial Appreciation of Specialized Executive Training

At this point one may say that this is all very good training, but that he does not see how these men can be of particular value in one's own organization, which may be a furniture plant or an auto-body plant. The best answer to such a question is that some of these industries are taking these men and are finding them advantageous to the organization. These men are progressing and are securing the better positions and becoming the executives. The industry as well as the student must have some vision and must realize that four years of training in a rather general field have not prepared a man to make a success of any job that he may be given. It must be remembered that while he has had opportunity of operating an experimental kiln or wood-treating plant or has had some practical experience during vacation periods, he is nevertheless only a student who has a good background for further training. The large progressive industries of this country, and many smaller ones too, often take the college men into the organization for a special course of training which will point or adapt them to their particular work. Judgment should be used in working the man into the organization.

Industrial Demand Stimulates Educational Output

The more rapidly the woodworking industry calls for men of special training, just that much more rapidly will the forestry schools be able to give courses that will be more applicable to this industry. It would seem that preparation for this work will

soon include such courses as kinematics, machine design and layout, mechanics, power, shop practice, factory management, economics of manufacturing, industrial engineering and investigations, time and motion studies, a detailed study of the uses of wood, glues, plywoods, wood finishes, and industrial psychology. These fourteen additional courses would have to be given in place of some of those already outlined. Those least applicable to the problems of the woodworking industry would have to be eliminated. Some of those eliminated might be the botany courses, zoology, entomology, surveying, mensuration, forest history, planting, lumber salesmanship, and one course in timber preservation.

Course of Study Recommended

With this change in courses a student will have had basic training courses, such as English, mathematics, languages, chemistry, physics, economics, and speech. He will have had such business courses as accounting, merchandising, transportation, factory management, industrial psychology, and economics of manufacturing. The courses pertaining to wood would be growth of forests, forest economics and distribution, wood-technology courses, timber physics, forest pathology, logging and lumber manufacture, forest products other than lumber, problems of the lumber and woodworking industries, seasoning and preservation of wood, uses of woods and grades, glues, plywoods, and finishes. The engineering courses would be mechanics, kinematics, machine design and layout, power, shop practice, industrial engineering and investigations, and time and motion studies.

This variety of courses when summarized shows ten general courses, six business courses, fifteen courses pertaining to wood, and nine to engineering. This gives a total of forty courses, all of which would be of three hours per semester, except English, mathematics, modern language, and wood technology. These four subjects would be of three hours each for two semesters. If one desires more mathematics, of course there could be some elimination of modern languages, or other similar changes could be arranged. It should be noted also that forty courses for four years is an average of 15 hours' credit per semester, which is a rather light schedule. It is therefore possible to add one course each semester or eight courses in four years. These eight courses could all be in one of the four groups of subjects or more or less evenly spread among all groups, depending on how much importance was placed on certain subjects by different individuals.

The authors feel that the proportion shown in the foregoing is about right, but that is a matter of opinion. Having been engaged in training men for this field of work for many years and knowing the work and the problems that these men have to meet in this line of work and knowing further of the desires of managers in hiring young men for this work, they feel fairly certain of the needs in these four groups of study.

Specialized Training

Wood, machines and equipment, purchasing, merchandising, and costs are the big problems of a woodworking factory. One man cannot be an expert in all of these fields, but he can know much about the most important ones and can have a general idea of the least important. Merchandising and cost-accounting men are being well prepared by many schools, but what school prepares a man who understands wood from the forest to the finished product? When the price of white oak of a certain grade reaches a certain point, is it advisable to buy another grade of this wood or can another wood be substituted, and what grade in this substitute wood should be used? If a door that has been hung six months pulls apart at the joints or cracks across the panels, what is the matter? Why did the door next to it show no such tendencies? These are typical of hundreds of such problems that for the most part are unsolved or only partly solved because the leaders in this industry have not been trained in the subject of wood. While the problems of a woodworking plant are of several natures, as already indicated, the chief problem and the problem that is least understood is generally that of its raw material, wood.

Cooperation Imperative Between Industry and Schools

The industry and the forestry schools can well afford to become better acquainted. The industry knows too little of the work that the schools are doing, and it is offering few or no suggestions of how better to prepare men for its use. The faculties of the schools have had too little practical contact with the industry and seem to hesitate to keep that contact frequently renewed and alert to the problems and conditions. The progress of the woodworking industry depends upon the training of the young men who are entering this industry.

WDI-53-7

Developments in the Stabilization of Painting Practice for Wood

By F. L. BROWNE,[1] MADISON, WIS.

Painting practice is changing from a craft to a part of engineering. The Forest Products Laboratory has tested the painting characteristics of softwoods. The tests included edge-grain and flat-grain boards, light woods consisting mostly of spring-wood and heavy woods with wide bands of summer-wood, white lead and prepared paint, various combinations of paint, linseed oil, thinner, and drier for the priming coat, and aluminum paint as a first coat. Conditions of dryness and of humidity entered into the tests. The basic factors responsible for the chief uncertainties of paint behavior were studied, and the way is pointed for a possible stabilization of painting practice for wood through further research.

PAINTING practice is in course of transition from a craft to a part of engineering. (1)[2] The breakdown of the apprenticeship system, the multiplication of new materials available for painting, the increasing variety of the surfaces to be painted, the accelerating tempo of building and manufacturing operations, and the rising standards of acceptable service have overwhelmed the old-fashioned painter. However, the engineer is not yet fully prepared for his new responsibilities because the background of technical data on painting practice is fragmentary and largely unreliable, and means of measuring the serviceableness of paint coatings is lacking. A specification for a durable exterior paint finish cannot be written with the same assurance of success that is possible in designing a structure to carry a given maximum load. Quality in a paint job is judged primarily by the costliness of the materials and the labor of applying them rather than by dependable yardsticks of performance.

Under the circumstances it is not surprising that painting practice is far from stabilized. Many kinds of paint are sold for similar uses, and opinions about their relative merits differ bewilderingly. Details of applying paint vary widely. New woodwork is sometimes painted with two coats, sometimes with three. Admixtures of oil, thinner, and drier are variously recommended. There is uncertainty about the limitations of weather, condition of the surface, and drying time between coats within which painting may be done safely. When paint jobs turn out unsatisfactorily, the cause of failure is frequently difficult to determine. All too frequently coatings give way soon after they have been applied, even though conscientious efforts were made to do first-class work. When reasonable length of service is attained, it is difficult to determine when a coating ceases to function properly and requires renewal. Opinions then differ about the way to prepare the surface for repainting and how to repaint it.

A major source of confusion about painting practice for exterior woodwork arises from the marked variation in durability of coatings on different kinds of wood. The fact has long been recognized, but statements about the kinds of wood that give good or bad service and what should be done about it have been strikingly contradictory. Some have thought that certain woods are inherently lacking in paintability and should not be used in places where painting is important. Others have held that each kind of wood requires an appropriate adjustment of the proportions of pigment, oil, and thinner in the priming coat, but the formulas for each kind of wood have never been stated definitely, that being left to the painter's judgment. Still others have maintained that for some woods the turpentine in the primer should be replaced by volatile liquids of greater solvent power. Many special priming paints have been proposed for use on woods upon which paints fail soonest.

Forest Products Laboratory Tests

To provide reliable information about such moot questions the Forest Products Laboratory in 1924 began an experimental study of the painting characteristics of softwoods. (2) Test fences were established at 11 places in the United States representing a great range in climates. On the fences, panels of 18 species of softwoods were exposed and painted. In general, at every station there were four panels of each species, two made with flat-grain boards and two with edge-grain boards. Of these one panel of flat-grain and one of edge-grain boards were painted with three coats of white-lead-paste paint and the other two panels with three coats of lead and zinc prepared paint.

In the 1924 tests no attempt was made to adjust the proportions of pigment, oil, and thinner in the priming coat according to the kind of wood painted. All woods were painted in exactly the same way. The mixtures of white-lead-paste paint were:

	First coat	Second coat	Third coat
Paste white lead (92 per cent pigment), lb	100	100	100
Raw linseed oil, gal	4	1½	3½
Turpentine, gal	2	1½	1
Paint drier, pt	1	1	1

The lead and zinc prepared paint consisted of:

Pigment, 64 per cent by weight, composed of:	Per cent by weight
Basic carbonate white lead	60
Zinc oxide	30
Asbestine	10

[1] Senior Chemist, Forest Products Laboratory, maintained at Madison, Wis., by the Forest Service, U. S. Department of Agriculture, in cooperation with the University of Wisconsin. Dr. Browne joined the staff of the Forest Products Laboratory in 1918, when he engaged in developing water-resistant glues, particularly for use in aircraft. When investigations of wood finishing were begun in 1922, he was placed in direct charge of the experiments. He is a graduate of the course in chemistry at Cornell University and obtained the doctorate at the University of Wisconsin in colloid chemistry. He is a member of the American Chemical Society and of the Society of Sigma XI, a fellow of the American Association for the Advancement of Science, and an assistant editor of *Chemical Abstracts*.

[2] The numbers in parentheses throughout the paper refer to the List of References at the end.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

Vehicle, 36 per cent by weight, composed of:	Per cent by weight
Raw linseed oil	90
Turpentine	5
Liquid drier	5

For the priming coat 1¼ pints of raw linseed oil and 2 pints of turpentine were added to a gallon of this paint. For the second coat 2½ pints of turpentine were added to a gallon. For the third coat the paint was applied without any addition.

All test stations were visited at least once each year by the same inspector. During the first year or so the appearance of the paint coatings changed materially. (3) The gloss faded, the white surfaces became dirty, then the coatings began to disintegrate at the surface in the form of a fine powder and some of the dirt became dislodged, and finally the coatings began to check in fine, presumably superficial fissures. There were interesting differences in appearance between coatings of the two kinds of paint and between the different exposure stations, but the kind of wood beneath the coating had very little effect upon its appearance. However, as the tests continued, other changes set in that varied markedly with the kind of wood. These changes were of two sorts; namely, in the integrity of the coating, and in that of the wood itself. Sometimes deep slits developed in the coating at the edge of which the coating curled up and broke off in little pieces, laying the wood beneath bare. Sometimes paint checks finally became deep, interlacing cracks, and little areas of coating outlined by the cracks fell off bodily, leaving the wood bare. Such changes were recorded as deficiencies in the integrity of the coating. But sometimes checks opened in the wood where otherwise the coating seemed to be intact. Such changes were recorded as inadequate protection by the coating against wood weathering.

Results of the 1924 Tests

The most important facts revealed by the 1924 tests were the following: (4)

Summer-Wood and Spring-Wood. The variable behavior of paint coatings on the softwoods is due primarily to difference in behavior on summer-wood and spring-wood. Failure of aged coatings in integrity usually begins over summer-wood long before it sets in over the neighboring spring-wood, and therefore failure in coating integrity proceeds most rapidly on boards that contain the greatest amount of summer-wood.

Summer-wood is the harder, darker-colored part of the annual growth ring in the wood. Structurally it differs from spring-wood in that the wood cells are flattened and have thicker walls and smaller cavities than the wood cells in spring-wood. Summer-wood is roughly three times as heavy as spring-wood. Experience in impregnating wood with liquids proves that the heavy summer-wood is more easily and deeply penetrated by liquids than the light spring-wood. Experiment proves that the liquids in oil paint follow the same general rule and penetrate more deeply into summer-wood than they do into spring-wood, although there has long been a contrary impression among painters. The pigments of oil paint are too large to penetrate beyond the cavities of those wood cells that were cut open in forming the surface of the board. Like other liquids, resins exude more easily from summer-wood than they do from spring-wood, but there is no evidence that summer-wood actually contains more resin than spring-wood.

Aged coatings apparently do not adhere to wood substances as glue does, but cling to the wood by a mechanical embedding of the paint in the open cell cavities at the surface, much as plaster clings to lath. Summer-wood, with its small cavities, furnishes inadequate anchorage so that small pieces of aged coating easily become detached and fall off. However, if the band of summer-wood is very narrow, the little pieces of coating may retain sufficient grip in the spring-wood on either side to remain in place, arching over the summer-wood.

Some Woods Require More Effective Protection Than Others. A second factor causing variable behavior of coatings on softwoods is the fact that some woods require more adequate paint protection to prevent wood-checking, which is the first sign of wood weathering. (5) Test panels were often observed in which the wood had begun to check although the coating otherwise seemed to remain intact. The woods on which this happened were the kinds that quickly develop conspicuous checks and cracks when exposed to the weather without paint protection. Frequently the wood checks became centers from which failure of the coating in integrity progressed.

Edge-Grain and Flat-Grain Boards. Coatings remain intact longer on edge-grain boards than they do on flat-grain boards of otherwise similar wood. The difference in behavior is accounted for by the disposition of summer-wood at the surfaces of the two kinds of boards. Since the surface of an edge-grain board lies roughly in a plane along a radius of the tree, the bands of summer-wood are reduced to the narrowest width possible. The surface of a flat-grain board, on the other hand, is in a plane approximately tangent to some of the growth rings of the tree, so that the bands of summer-wood at the surface of the board may flare out into large areas.

Edge-grain boards weather-check less easily than flat-grain boards, doubtless because they swell and shrink less in width, and therefore coatings continue to furnish sufficient protection longer on the edge-grain boards.

Bark Side and Pith Side of Flat-Grain Boards. One side of a flat-grain board is always nearer the bark and the other nearer the pith of the tree from which it was cut. The bark side makes a better surface for painting than the pith side. On the pith side of some boards the summer-wood of one annual ring may separate from the spring-wood of the next ring and curl upward in a sharp, easily splintered edge. Paint coatings are often unable to prevent such grain shelling, and consequently the coating may be badly disrupted.

Density and Ring Width. Since summer-wood is much heavier than spring-wood, the density of a piece of softwood is a fairly good measure of the proportion of summer-wood in it and therefore of its painting characteristics. Paint fails sooner on heavy boards, because they contain more summer-wood than light ones. However, another factor must also be considered—namely, the width of the annual growth rings (usually recorded as the number of rings per radial inch of the log). When the growth rings are narrow (many rings per inch), there may be a fairly high proportion of summer-wood, and yet the bands may be narrow. Such wood holds paint better than wood of equal or slightly lower density in which the growth rings, and consequently the bands of summer-wood, are wide.

The lumber of many species varies widely in density and in ring width, and the painting characteristics vary correspondingly. Any classification of species with respect to painting characteristics is therefore a rough approximation at best and involves much overlapping; that is, light, narrow-ringed boards of a given species may be superior, from the point of view of painting, to heavy or wide-ringed boards of species assigned higher positions in the classification. In general, edge-grain boards of any species are as good or better for painting than flat-grain boards of the species assigned to the next higher class. Subject to these reservations, the softwoods were classified for painting characteristics on the basis of the 1924 tests as set forth in Table 1, which lists also the relative amounts of the species cut into lumber in 1927.

Lumber Grade and Knots. The principal defects that form the basis for grading lumber are disadvantageous from the point of view of painting. Coatings over knots often discolor, crack, and fall off, and the wood of the knots checks conspicuously. Pitch often exudes through coatings over pitch pockets, pitch streaks, or pitchy wood. Low-grade lumber is therefore less desirable for painting than high-grade lumber of the same species unless the low-grade lumber is remanufactured in such a way that the defects are cut out. Even then the advantage may still lie with the high-grade lumber, because as a rule the high-grade lumber is cut from the outer portions of the log where the growth rings are usually narrower than they are nearer the center of the log.

TABLE 1 CLASSIFICATION OF WOODS FOR PAINTING CHARACTERISTICS AND THE ANNUAL PRODUCTION OF THESE WOODS AS LUMBER

Classification, Using U. S. Forest Service Common and Botanical Names	Percentage of all softwood lumber cut in 1927
Group 1—Woods on which coatings served longest, both in integrity and in protection:	
Cedar, Alaska; *Chamaecyparis nootkatensis*	1
Cedar, Port Orford; *Chamaecyparis lawsoniana*	
Cedar, Western red; *Thuja plicata*	
Cypress, Southern; *Taxodium distichum*	2
Redwood; *Sequoia sempervirens*	2
Group 2—Woods on which coatings failed in protection sooner than on woods of Group 1:	
Pine, Northern white; *Pinus strobus*	5
Pine, Western white; *Pinus monticola*	
Pine, sugar; *Pinus lambertiana*	1
Group 3—Woods on which coatings failed in both integrity and protection sooner than on woods of Group 1:	
Fir, white; *Abies concolor*	1
Hemlock, Eastern; *Tsuga canadensis*	7
Hemlock, Western; *Tsuga heterophylla*	
Pine, Western yellow; *Pinus ponderosa*	10
Spruce, Eastern; *Picea spp.*	2
Spruce, Sitka; *Picea sitchensis*	
Group 4—Woods on which coatings failed soonest, especially in integrity:	
Douglas fir; *Pseudotsuga taxifolia*	30
Larch, Western; *Larix occidentalis*	1
Pine, Southern yellow; *Pinus spp.*	38

Heartwood and Sapwood. Few differences in the behavior of coatings on heartwood and sapwood have been observed so far. In the few cases that have occurred, the advantage has sometimes been with the heartwood and at other times with the sapwood.

Extractive Substances Characteristic of Species. Although the primary cause of variation in the behavior of coatings on different species is found in the amount and distribution of summer-wood, a factor of secondary importance is the presence in certain woods of characteristic substances that can be separated from the woods by extraction with suitable solvents. Thus cypress and redwood each contain a substance peculiar to the species that affects the behavior of paint. When paint is applied to either of these woods while they are wet with water, the coatings will not harden until the moisture content has been reduced to a reasonable amount. On the other hand, coatings cling to the summer-wood of redwood and cypress somewhat longer than they do to the summer-wood of most other species. It seems likely that the extractives in redwood and cypress have a favorable effect on the durability of coatings.

All pines contain rosin or a similar oil-soluble acidic substance. Free organic acids in linseed oil are known to be harmful to paints containing zinc oxide, but not so harmful to straight white-lead paint. It was therefore to be expected that the lead and zinc paint would not prove quite so durable on the pines as it did on other woods of similar density and ring width, but that no such differences between pines and other woods should be observed in the case of the straight white-lead paint. The results of the tests confirmed this expectation.

Results in Different Climates. The same classification of the woods was found to apply in all climates, but the extent of variation differed materially. In climates where there are long periods of extreme dryness, failure of coatings by sloughing bodily from summer-wood takes place most rapidly and most characteristically. Such conditions accentuate the discrepancies in behavior on different woods. Where the humidity rarely falls very low, coatings cling longer to the summer-wood, the paint itself has more chance to disintegrate or wear away, and the difference between species is somewhat less marked.

Of the two paints used in the tests, one proved distinctly superior to the other on all woods in arid climates, but just as definitely inferior on all woods in the warm, humid climate of Florida. In the intermediate climates one paint often proved the more durable on the pines, while the other lasted longer on woods other than the pines.

The 1925 Primer Tests

A second series of tests was started in 1925 to determine how far the durability of coatings on woods containing much summer-wood can be improved by altering the proportions of pigment, oil, and thinner in the priming coat, by replacing turpentine with special solvents, or by using special priming paints. The test panels were divided into two halves, of which one was painted by the standard procedure followed previously in the 1924 tests, while the other half was painted by one of the special procedures to be studied. Thus comparison of new and old procedure could always be made on the same boards. The woods studied in 1925 were Southern yellow pine, Douglas fir, Western larch, Western yellow pine, Eastern hemlock, Western hemlock, and Southern cypress.

Results of the 1925 Tests

The following results were obtained in the 1925 tests: (6) *Proportions of Oil and Thinner in the Primer.* In spite of the old and widely accepted tradition that the durability of paint coatings on woods containing much summer-wood can be improved by mixing the priming coat with more than the usual amount of turpentine (and correspondingly less oil and pigment), the tests proved that the priming-coat proportions have very little effect upon the serviceableness of the coatings. If the comparisons had not been made on the same boards, no differences at all would have been detected. As it was, the durability of the coatings with turpentine-rich primers was judged slightly inferior to that with the standard primer; clearly the comparisons between species made in the 1924 tests would not have been altered in any way by changing the proportions of the priming-coat ingredients.

The result of these experiments is reasonable. Thinning with turpentine is usually recommended in the belief that deeper penetration of the paint oils will secure firmer adhesion of the coating. However, penetration to begin with is deeper in summer-wood, from which coatings come loose first, than it is in spring-wood, to which coatings cling longer. The theory is therefore discredited at the outset.

Special Solvents as Paint Thinners. Replacement of turpentine with volatile liquids that are better solvents for the oils and resins in some woods has been recommended as a means of improving paint service. Three series of experiments have been made by the Forest Products Laboratory to test the theory. The volatile liquids included gum spirits turpentine, steam-distilled turpentine, destructively distilled turpentine, turpentine oxidized by bubbling air through it, petroleum distillates ranging in volatility from gasoline to kerosene, petroleum distillates from four types of crude oil, benzol, and coal tar naphtha.

Tests were made on Southern yellow pine, cypress, and Eastern hemlock.

The effects of varying the volatile liquid were in all cases so slight that they can be of interest only from the point of view of theory. None of the liquids gave better results than turpentine on any wood. There were indications that oxidized turpentine added slightly to the durability of the coatings. The beneficial effect of turpentine must therefore be attributed to the nonvolatile residue left when turpentine evaporates in the presence of oxygen or to a desirable alteration in the drying of linseed oil in the presence of the turpentine product.

Special Priming Paints. Five special priming paints were studied in the 1925 series of tests. Of these two had very little effect on the behavior of the coatings and two proved definitely harmful to the durability. The fifth primer, aluminum paint, materially retarded the loosening and detachment of coatings from summer-wood and thereby prolonged the life of coatings

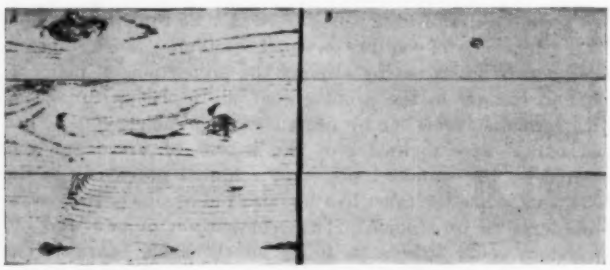

FIG. 1 CHARACTERISTIC FAILURE OF A PAINT COATING BY FALLING OFF THE SUMMER-WOOD AND THE BENEFICIAL EFFECT OF ALUMINUM PRIMER IN RETARDING SUCH BEHAVIOR

(The left-hand part of the panel, marked *A*, was painted according to the usual procedure of applying three coats of prepared paint, of which the first contained a little extra linseed oil and turpentine. The right-hand part of the panel, marked *B*, received first a priming coat of aluminum paint, followed by exactly the same second and third coats of paint that were applied on *A*.)

on woods containing much summer-wood. Fig. 1 illustrates the improvement in paint service brought about by priming with aluminum paint.

Aluminum priming paint (7) is made by adding polished aluminum bronze powder to a suitable liquid just before it is to be applied. From $1^1/_2$ to 2 lb. of the powder is stirred into the liquid; grinding in a paint mill is neither necessary nor desirable. The liquid should be either a kettle-bodied linseed oil thinned to suitable viscosity with paint thinner and drier or a long oil spar varnish (at least 80 gal. of oil per 100 lb. of resin). Ordinary spar varnish may be mixed with boiled oil, but the cost is likely to be greater. Aluminum priming paint must be thoroughly dry before the top coats of paint are applied over it.

Other priming paints or priming procedures have been suggested in recent years. Some of them are being tested by the Forest Products Laboratory or by paint manufacturers. (8)

ABNORMALLY EARLY PAINT FAILURES ON HOUSES

Much uncertainty about painting practice has arisen in the past because paints that give excellent service when exposed on test fences sometimes fail in an unreasonably short time, perhaps within a year, when applied on houses. Within the last few years observations by the Forest Products Laboratory (9) and by the West Coast Lumbermen's Association (10) have shown that such difficulties are due neither to faulty paint nor to defective lumber, but are caused by improper methods of drying the building moisture in new buildings, errors in designing the structure, faulty construction, or unusual conditions of occupation. The essential factor is water gaining access to the back of the painted boards either through leaking joints of one kind or another or by condensation from moist air coming in contact with the backs of the boards during cold weather. Many details that frequently prove sources of trouble have been described. The only sure cure for such ills lies in preventing access of water to the backs of the painted boards. No paints now on the market are proof against moisture failures of this kind, and no woods are immune to them.

CONCLUSION

Studies in recent years have contributed largely to the stabilization of painting practice for wood by removing much of the mystery and vague speculation that has beclouded the subject and also by setting forth clearly the basic factors responsible for the chief uncertainties of paint behavior.

The durability of coatings on different softwoods varies widely because aged coatings do not adhere satisfactorily to summer-wood and the amount and distribution of summer-wood in softwoods ranges between wide limits. To a limited extent paint service may be improved by selecting, for purposes where painting is important, woods that are light and have only narrow bands of summer-wood. However, painting is usually only one of many considerations in choosing a wood, and other requirements often dictate the selection of woods with wide bands of summer-wood. Furthermore, Table 1 indicates that by far the greater part of the available lumber supply is of kinds that contain prominent summer-wood.

The woods with wide summer-wood bands can be improved for painting purposes by cutting them as far as possible so that edge-grain surfaces are exposed for painting. The flat-grain boards should be surfaced so that the bark side rather than the pith side is exposed.

Further improvement in paint service on woods containing much summer-wood is not to be sought in special proportioning of the oil and thinner in the priming coat or in choosing unusual volatile liquids. The painter may remain free to employ these variables to facilitate application. Thus he may vary the proportion of thinner to control the consistency and spreading rate of the paint.

The durability of paint coatings on woods with wide bands of summer-wood can be increased by priming them with a properly made aluminum paint, given ample time to dry.

Abnormally early failures of coatings are not due to the paint nor to the wood, but rather to unhealthy moisture conditions which must be cured before acceptable service can be expected.

However, after full advantage has been taken of the foregoing means of improvement, painting practice for wood still falls short of the standards that engineers expect of the materials with which they work. Failure of coatings by bodily detachment from the wood, leaving the surface bare, is inherently unsatisfactory because it leaves a part of the wood temporarily unprotected, presents a difficult surface for repainting, and affords an insecure foundation for the new coating. The ideal coating would wear away evenly and remain continuous and firmly adherent until the need for repainting becomes clearly apparent in lack of opacity. A real stabilization of painting practice for wood cannot be reached until this ideal is achieved through research.

Grading Timber for Strength

By LEYDEN N. ERICKSEN,[1] WASHINGTON, D. C.

The paper deals with the development of grading rules for structural timbers, the principles involved, effect of structural features on strength, and the application of the principles in commercial practice. Structural grading rules are based on the provisions of the American Lumber Standards, developed by the combined efforts of lumber producers, distributors, specifiers, and consumers, under the auspices of the U. S. Departments of Commerce and Agriculture. Structural material is divided into classes according to size and use: horizontal load-bearing members such as joists, planks, beams, and stringers, and vertical compression members, as posts and columns.

The strength of wood members is influenced by the density of the wood, moisture, seasoning, and the size, location, and number of strength-influencing factors present, such as knots, shakes, checks, and slope of grain. Heartwood, sapwood, and wane are more important from other points of view than for their influence on strength. Principles of structural-material grading have been applied in a practical manner by lumber-manufacturers' associations in drawing up commercial grading rules.

Safe working stresses for various grades and different conditions of exposure have been established in accordance with strength of clear wood, effect of strength-influencing factors permitted, the effect of seasoning, time of loading, and the characteristics of each species. Basic principles can also be applied to general construction material carried in retail lumber yards, thus insuring maximum strength and efficient utilization.

PUBLISHED grading rules for structural material in use at present were established by lumber manufacturers' associations upon the basis of the general provisions and structural grade examples given in the American lumber standards. Standards as a whole are recommended basic provisions covering the manufacture, grading, and marketing of softwood lumber products, including yard lumber, factory and shop lumber, and structural material. All organized groups interested in lumber, including producers, distributors, specifiers, and consumers, have had a part in their development. They were developed under the auspices of the U. S. Departments of Commerce and Agriculture, and are published in Simplified Practice Recommendation R 16-29—Lumber, otherwise known as the "Fourth Edition of the American Lumber Standards."

Section IV of the Standards applies to structural material. It is intended for use as a general guide in the preparation by lumber manufacturers of grading rules for structural material in their particular woods. Because of variations in the inherent characteristics of different species, associations must make such adaptations in these provisions as may be necessary for their species.

Classes of Structural Material

Before discussing the grading of timber for strength and the factors which must be considered it is necessary first to consider the classes into which such material is divided from the standpoint of size and use. Three main classes are so recognized: (1) Joists and planks, (2) beams and stringers, and (3) posts and timbers.

Joists and planks include material from 2 to 4 in. thick and 4 in. and up in width. Among its principal uses are floor joists, rafters, factory flooring, planks, bridge planks, and platform joists.

Beams and stringers include material 5 in. and thicker and 8 in. and over in width. They are used for heavy horizontal load-bearing members, such as bridge, trestle, and wharf members, beams in heavy mill construction, and similar uses.

Posts and timbers include material 6 in. by 6 in. and larger, and square or nearly square in cross-section. Material 5 in. square is sometimes included. It includes members used vertically as columns and such horizontal members as caps and sills.

Factors Affecting Strength

The purpose of grading timber for strength is to segregate pieces into classes having definite load-bearing values. This load may be such that it subjects the member to a bending stress, to compression either parallel with or perpendicular to the grain, to tension, or to a shear stress. All of these are considered in the grading of structural material.

The strength of wood members and their ability to resist stresses are governed by several factors. First to consider is the strength of the clear wood of the species in question, then the character of growth and wood structure in the individual piece, and finally the structural features which may be present, such as knots, pitch pockets, shakes, and checks.

Species and Growth

The strength of clear wood of all species varies with its density, which is a measure of the amount of wood substance present. If it were compressed to the point where all air spaces were excluded, the wood of all species would have the same density. Because some woods have thicker cell walls and smaller cell cavities than other woods they contain more actual wood substance per unit of volume and are correspondingly heavier and stronger. Likewise, there is a considerable range in density within a single species with a corresponding range in strength properties. All properties are not influenced in the same degree by variations in density; bending strength and stiffness increasing approximately as the first power, hardness and strength in compression across the grain as the square, and shock resistance by a slightly higher power of the density.

[1] Forest Products Engineer, National Lumber Manufacturers Association. Mr. Ericksen was graduated, with B.S. in Forestry, from the University of Minnesota. He was employed for five years at the U. S. Forest Products Laboratory in investigations of industrial uses for wood and the grading of hardwood lumber. He was for one year with the Western Electric Company, engaged in development work in connection with wood requirements. For the last three years he has been employed by the National Lumber Manufacturers Association in work dealing with lumber standardization and grading and lumber specifications.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

Density

In some softwoods the density may be estimated closely by the proportion of summerwood present, the darker harder portion of each ring of annual growth. Advantage is taken of this in the grading of structural material in Douglas fir and Southern pine. For example, in order to meet the structural grade provisions for these woods, pieces selected for density must contain at least one-third summerwood and have a rate of growth of at least six annual rings per inch, as measured in the prescribed manner on either end. This is illustrated in Fig. 1.

Fig. 1 Dense Six-Inch by Eight-Inch Beam or Stringer
(This piece averages 6 annual rings per inch and 51 per cent summerwood, the dark portion of the annual ring. It is a good example of "dense" material.)

Fig. 2 Close Grain Six-Inch by Six-Inch Post or Column
(This post averages 15 annual rings per inch and contains 30 per cent summerwood. It is therefore classified as "close grain" material, not having the 33⅓ per cent summerwood necessary to be classed as dense.)

Material which has less than six annual rings per inch is considered as meeting the density requirement if it contains one-half or more summerwood. Southern pine or Douglas fir meeting the summerwood and ring requirements is termed "dense."

Close Grain

In some species material having medium to narrow annual rings, as illustrated in Fig. 2, also is recognized as being superior in strength to that which has wide annual rings. This is known as "close grain" material, and although it is not as great an assurance as density, selection for rate of growth provides material suitable for many purposes. Close grain, i. e., not less than six nor more than 20 annual rings per inch, with defects limited as in the dense grades, is provided in several structural grades of Douglas fir. Similarly, the structural grades of California redwood provide for material having not less than 10 rings per inch with the maximum number limited to 25 and 35, depending upon the grade. In other softwoods material having a medium rate of growth has good strength properties depending on other factors such as knots, shakes, and slope of grain.

Fig. 3 Six-Inch by Eight-Inch Post or Column
(This piece averages 5 annual rings per inch and contains 25 per cent summerwood. It therefore is not classed either as close grain or dense material.)

Effect of Moisture on Strength

The moisture present in wood has an important bearing upon its strength properties. Wood in the standing tree or when freshly cut contains moisture in two forms, hygroscopic moisture which is contained in the cell walls, and free moisture which is contained in the cell cavities. As green wood dries it first loses the free moisture until it reaches a moisture content of from 25 to 30 per cent, at which point the free moisture is gone and the wood begins to give up its hygroscopic moisture. Changes in moisture content above this point, called the "fiber saturation

point," have little or no effect upon strength properties. As wood loses moisture below the fiber-saturation point its strength properties increase. As wood dries, however, it shrinks, and in material of structural sizes shrinkage is usually accompanied by a certain amount of checking and splitting, as a result of which some of the increased strength due to drying is lost.

In addition, timbers in use may be subjected to a range of moisture conditions, from dry interiors to the continually wet conditions encountered in some exterior uses. All of these factors are considered in establishing working stresses for different conditions of use.

Knots

Knots are among the important strength-influencing factors which are considered in structural grading rules. Their influence depends upon their size, number, and location in a piece. The quality of a knot does not influence its effect upon the strength of a wood member, and no distinction, therefore, is made in structural grades between intergrown knots and encased knots or knot-holes.

Location of Knots

Since knots in certain parts of horizontal load-bearing members (beams and stringers) have a greater weakening effect than in other parts they are more severely restricted in such locations. They have the most influence when located near the top or bottom edges in the center portion of the length. In these areas knots are required to be smaller than toward the ends or on the center line of the wide (vertical) faces. No knots are permitted anywhere in the piece, however, more than twice the size of knot permitted at the point of maximum stress.

The structural grading rules of one lumber manufacturers' association limit the knots near the ends of pieces in the same manner as in the center portion, thus assuring ample strength.

The restrictions on the sizes of knots at edges of wide faces of joists are more severe than would be required for use flat as planks. Under practically all conditions of use, however, knots along the edges of planks are more objectionable than those along the center lines. The same knot limitations are therefore applied to material to be used either as joists or as planks.

In timbers used as columns knots of the same size have the same influence regardless of their location on the faces or in the length. Knots are therefore limited in the same manner in all parts of such timbers.

Measurement of Knot Sizes

The influence of knots also varies according to the area of their projection on the cross-section of the piece. They are therefore measured in a manner which most closely approximates this influence.

On wide faces of joists and planks the mean or average diameter of a knot is taken as its size, as shown at *B* and *C* in Fig. 4. In such thin and relatively wide material, whether used on edge or flat, this is a safe measure of the influence of knots on strength and has the additional advantage of being directly applicable to yard grades of lumber. This method of measurement can be applied to spike knots as well as to round and oval knots, and excludes those which would have too great an effect on strength.

The influence of a knot on the top or bottom faces of beams, stringers, joists, and planks depends largely on the extent to which the surface fibers are cut. This is measured by the projection of the knot on a line at a right angle to the edge, and the size of such a knot is accordingly taken as its width between lines parallel to the edges of the piece, as shown at *A* in Fig. 4.

The depth of penetration of a knot on the wide or vertical face of a beam or stringer is of great importance while the influence of the number of surface fibers cut, and the amount of grain distortion, is considerably less important than on the horizontal (top or bottom) faces. The smallest diameter of such a knot is, therefore, taken as the basis for measurement, as shown at *C* in Fig. 4.

In structural members used as posts or columns two factors must be considered in connection with knots: (1) The effect upon the strength of the member in compression parallel to the grain, probably best measured by the small diameter; and (2) the influence upon the bending strength when the column begins to fail, probably best measured by the projection of the knot on a line at right angles to the edge. The method of measurement which most nearly represents average conditions is the average of the maximum and minimum diameters, which accordingly is used in measuring knot sizes in posts and columns, as illustrated at *B* and *C* in Fig. 4. In short columns the area of the cross-section occupied by the knot is of primary importance, the factor of bending strength increasing in importance as the column gets longer.

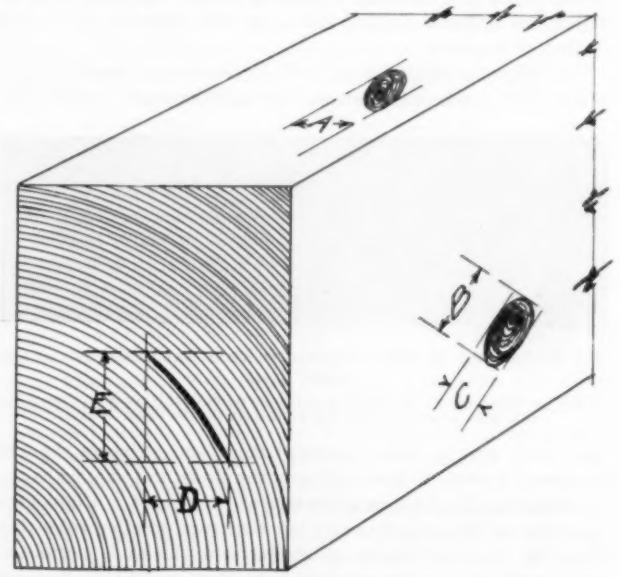

Fig. 4 Section of Structural Member Showing Method of Measuring Size of Defects

(Knots on narrow faces of beams, stringers, joists, and planks are measured between lines parallel to edges, as at *A*. Knots on wide, or vertical, faces of beams and stringers are measured on their smallest diameter, as at *C*. Knots on wide faces of joists and planks and on all faces of posts and timbers are measured on their average diameter, average of *B* and *C*. Shakes are measured on the end of the piece, in joists, planks, beams, and stringers between lines parallel to the wide faces, as at *D*; and in posts and columns in the direction in which the shake extends the greater distance, as at *E*. The illustration shows a side-cut timber, pith not present. Boxed-heart timbers contain the structural center of the tree, i. e., the pith.)

Knot Sizes

The size of knots is permitted to increase with the size of the piece. In narrow faces of beams and stringers up to 6 in. wide and in wide (vertical) faces of beams, stringers, and joists and faces of posts up to 12 in. wide, the increase is directly proportional to the width of the faces. Because of the greater distortion of grain around larger knots, with a correspondingly greater influence upon strength, the relation between sizes of permissible knots and the size of the piece in members larger than those mentioned is, however, limited to a smaller ratio, the increase being proportional to the square root of the wider faces to these sizes.

In addition to limiting the size of single knots, structural grading rules limit the number and aggregate size of knots within

certain areas of the length. In horizontal members the aggregate diameter of all knots in the center portion cannot exceed a certain proportion of the width of the face, depending on the particular grade under consideration. The aggregate diameter of knots in posts and columns is limited so that the size of all knots within any 6 in. of length does not exceed twice the diameter of the largest knots permitted in the particular grade under consideration.

Shakes and Checks

A shake is a lengthwise separation of the wood, which occurs usually between and parallel to the rings of annual growth. A check is a lengthwise separation of the wood, which occurs usually across the rings of annual growth. Shakes appear on the end sections of a piece of structural material as narrow openings, curved tangentially to follow the growth rings, while checks appear as narrow openings extending across the rings in a radial direction from the pith. Both may also appear on one or more of the four surfaces.

The effect of shakes and checks in horizontal members is to reduce their resistance to shear. Shake is measured on the ends

Fig. 5 Section of Joist Placed so That the Knot Is on the Upper Edge

(It has less influence on the strength of the member in this position than if the joist were placed so that the knot were on the lower edge.)

of a piece, and in joists, planks, beams, and stringers the size is measured between lines enclosing the shake and parallel to the wide faces of the piece, as illustrated at *D* in Fig. 4. Checks are measured in the same manner, but structural grading rules provide that no combination of shakes and checks is permitted which would reduce the strength more than would the allowable shakes.

Ordinarily shakes and checks have but little effect upon the strength of posts or columns. In such material the size of a shake is measured in the manner described, but across the end in the direction in which it extends the greater distance, as at *E* in Fig. 4.

Slope of Grain

Deviation in the direction of the grain of timbers away from a line parallel to the edges may be due to several causes. The fibers in the standing tree may incline in one direction or the other. Or, as a result of the natural taper in the tree, the grain of the wood in timbers having parallel edges may deviate. This deviation is called "slope of grain" and is expressed in terms of the amount of deviation that takes place over a certain length, as 1 in 20 or 1 in 15, meaning a deviation of 1 in. in a length of 20 in. or 1 in. in a length of 15 in. Until the slope of grain exceeds 1 in 40 there is not much reduction in strength. The effect of slope of grain greater than this depends upon the manner in which the piece is to be used and upon its location with respect to the top and bottom and in the length of the piece. It is of greatest importance on the top and bottom faces and toward the center of the length. It has less influence upon the strength of columns than upon horizontal members. Extreme cross-grain in columns, however, may cause checking as the piece dries. Slope for grain is measured over a distance sufficient to avoid the influence of short, local deviations.

Other Features Considered in Grading

In addition to the strength-influencing factors mentioned timbers have other characteristics which are considered in grading them for certain purposes. Among them are the proportion of sapwood and heartwood present, wane, and in some woods the presence of pitch pockets.

Heartwood and Sapwood

Contrary to the impression of many there is no inherent difference in strength between heartwood and sapwood, other things being equal. In timbers graded for strength, therefore, no restrictions need be made on the amount of sapwood present. Where decay resistance is necessary sapwood should be limited if the timber is to be used untreated. Sapwood absorbs wood preservatives more readily than heartwood, however, and if timbers are to be treated a large amount is desirable.

Wane

Wane is the absence of wood on the edge or corner of a timber resulting in the lack of a square corner. It is usually caused by the surface of a tree intersecting the edge of a timber. Wane ordinarily is not a serious factor from the point of view of its effect upon strength. It is considered rather because of its influence upon appearance, bearing areas, and nailing. Wane is measured according to its width as compared with the width of the faces on which it appears. While it could theoretically be permitted in all structural grades, the higher grades exclude it entirely.

Pitch Pockets

Pitch pockets are openings between the annual rings, usually containing pitch and sometimes bark. They do not have sufficient influence on strength to be classed as defects, but if a large number are present the piece should be examined closely to make sure that shakes are not present.

Commercial Application of Structural Provisions

The principles outlined have been applied in a practical manner by lumber manufacturers' associations in drawing up commercial grading rules for structural material. The permissible knots, shakes, slope of grain, and other factors are tabulated for each grade so that the exact description of the material permitted in individual grades can be judged without difficulty.

Material is graded at the mill by expert inspectors, who from long experience are able to segregate it accurately into the proper quality classes. In order to indicate to purchasers the grade of structural members many mills grade-mark structural material, stamping on each piece its exact grade. In this way the engineer or architect is assured that the material purchased and used conforms to specifications and will have the required strength properties.

Working Stresses for Structural Material

Definite working stresses have been established as a guide to the proper use for the various grades of structural material. Values are given for material exposed to three conditions of moisture: Continuously dry, occasionally wet but quickly dried, and more or less continuously damp or wet.

The values for material to be used in continuously dry conditions apply in sheltered locations and interiors not subjected to high humidities. The occasionally wet but quickly dried condition applies to such uses as bridges, trestles, grandstands, and open sheds.

The values for material to be used under more or less continually damp or wet conditions contemplate such uses as docks and wharves where the timbers are continually subjected to moisture.

The engineer preparing specifications should judge as to which of these classes best represents each project.

The subject of determination of working stresses is a subject complete in itself and can only be touched on here. The salient points considered in their derivation are outlined. Values are provided for extreme fiber in bending, compression parallel to grain, compression perpendicular to grain, horizontal shear, and modulus of elasticity.

Working stresses for material of structural sizes and quality are based on the strength of green clear wood as determined by the U. S. Forest Products Laboratory, Madison, Wis., in its comprehensive studies of the mechanical properties of woods and of the influence of various factors upon strength. In deriving them consideration has been given to the various strength-influencing factors outlined, the effect of seasoning and exposure, the effect of knots, their size, number, and location, the effect of shakes and checks, and the influence of cross or spiral grain.

In addition, allowance has been made for long-time loading, and the nature of the defects which may be characteristic of different species. Certain woods are more likely to contain shakes than others, some have their knots grouped more closely, some tend to check more in seasoning. All of these factors which study and experience have shown to be important have been considered.

An enormous amount of detailed and intensive research has been devoted to the study of the strength properties of wood and the effect of various factors on strength. The results of this work and the experience acquired through long study of wood have been used in setting up these stresses.

The influence of the strength-influencing factors varies for the different properties for which values are given. For example, the size and location of knots influence the stresses for extreme fiber in bending and in compression parallel to grain, but have little effect upon horizontal shear and compression perpendicular to grain. Shakes and checks influence horizontal shear principally and in extreme cases compression parallel to grain. Slope of grain influences the values for extreme fiber in bending and compression parallel to grain. The extent of exposure with the resulting range in moisture content has an effect upon the stress for extreme fiber in bending and compression parallel and perpendicular to the grain. The size of the piece affects the stresses for extreme fiber in bending, but not the other properties.

Density and close grain, in the woods in which they are considered in grading, permit an increase in the stresses for all properties except modulus of elasticity. Values for modulus of elasticity within a species are the same regardless of the grade, size of the piece, or exposure in use.

Working stresses are established on the basis of the lowest quality of lumber admitted in each grade. Each grade, however, contains material ranging in quality from that described up to that described for the next higher grade. Practically all of the material, therefore, could take higher stresses than those recommended. The published working stresses consequently are ultra-conservative and safe, and can be used with assurance.

Up to the present time grading rules and working stresses for structural material have been established and published by lumber manufacturers' associations for three species, Douglas fir, Southern yellow pine, and California redwood. Selection of other species, both softwoods and hardwoods, for structural purposes can be made according to the structural grade examples given in the American Lumber Standards.

These principles of grading structural material for construction uses can also be applied to stock used for such purposes as ladders, airplanes, masts, flagpoles, railroad-car sills, and crossarms. For example, slope of grain is important in lumber to be used in airplanes, where the best possible material is necessary. Likewise, in ladder stock, where failure may cause loss of life, both slope-of-grain and rate-of-growth limitations insure maximum strength.

These principles can be applied to much of the general construction lumber carried in retail lumber yards throughout the country, or by examination of the lumber on the job, material of good strength properties can be selected for certain structural parts of buildings where strength or stiffness is particularly desirable. For example, floor joists and other horizontal members can be so placed that the larger knots are on the upper edge, as in Fig. 5 rather than on the lower edge where they would have a greater effect upon the strength. It has been established that the load-bearing capacity of horizontal members of structural grade is increased up to $^1/_8$ or more when the better edge is placed down. Present working stresses are based on the assumption that each member may be used with the poorer edge down, and are consequently lower than they could be safely if care was taken to place the better edge down. This can readily be done on the job, however, thus assuring maximum strength. In some woods a considerable number of pieces in retail yards will be found to meet the density and close-grain requirements of the structural grades and thus can be depended upon to have good strength properties. By applying these principles advantage can be taken of the maximum strength of the lumber and the most efficient utilization will be effected.

Dust Explosions, With Special Reference to Woodworking Industries

By HYLTON R. BROWN,[1] WASHINGTON, D. C.

Explosions in flour mills have been common, but now the hazard is recognized in grain elevators, starch factories, sugar refineries, woodworking plants, textile mills, and other factories in which materials in the form of dust are manufactured. The woodworking industry is considered susceptible to this danger, especially since there is created a great quantity of dust from saws, planers, and sanders, and the recent manufacture of wood flour. More than thirty explosions in woodworking plants have been investigated. These indicate that wood dust is more easily ignited than some of the grain dusts. Precautionary measures are suggested, and regulations have been tentatively adopted for the prevention of dust explosions in wood-flour manufacturing establishments.

IN RECENT years the investigation of dust explosions and the development of methods of preventing dust ignitions have been extended by the Chemical Engineering Division of the Bureau of Chemistry and Soils in the U. S. Department of Agriculture to include the various industrial plants in which the hazard is known to exist. The first dust explosions recorded occurred in flour mills, and for many years such explosions were the only ones reported. Now the hazard is recognized in grain elevators, starch factories, sugar refineries, woodworking plants, textile mills, and factories in which rubber dust, sulphur dust, metallic dusts, powdered milk, chocolate, and cocoa, or other combustible materials in the form of dust are manufactured or handled.

Changes recently made in the industrial field, both in the manufacturing processes and in the utilization of by-products, have served to create a dust-explosion hazard in many plants not previously considered susceptible. The woodworking industry is an example of this type. Larger scale operations creating greater quantities of dust from saws, planers, and sanders have increased the possible hazard, and the demand for wood flour has induced some operators to reduce their scrap to powdered form. Even where the scrap is used for fuel, hogs reduce the material to small size so that it can be transported mechanically, and in so doing frequently create sufficient fine dust to form an explosive mixture.

More than thirty explosions in woodworking industries have been investigated, including explosions of wood dust, wood flour, wood pulp, and sawdust. A number of lives were lost, and many workmen were injured in these explosions which the investigations showed were caused principally by fires, overheated bearings, and electrical sources of ignition. A great many of the wood-dust explosions occurred in shavings vaults, especially ones in which the fine dust was blown into the vault with the shavings. A vault of some kind is generally provided for the collection of the refuse from the various machines in a woodworking plant, and this is the most likely spot where an explosion might be expected in the average plant.

Laboratory Tests

In the laboratory, tests have shown that wood dust is more easily ignited and produces higher pressures than some of the grain dusts which experience has taught are capable of producing tremendous pressures and completely destroying concrete and steel structures when the proper mixture of dust and air is ignited.

These same laboratory tests, although not strictly comparable because they were made on samples of wood dust as received in the laboratory without regard to particle, size, or moisture content, show a considerable variation in the results obtained with different kinds of wood dust, and also indicate that the upper and lower limits of concentration may vary greatly for different dusts.

For instance, in a comparison of uniformly fine redwood and white pine wood flour it is shown that with a concentration of 0.1 oz. per cu. ft. the redwood produced a pressure of 2 lb. per sq. in., while the white pine produced a pressure of 12 lb. per sq. in. However, when the concentration was increased to 0.4 oz. per cu. ft., the difference in pressure was not so great proportionally, being 19 and 34 lb., respectively.

In another series of tests with samples collected at Southern woodworking plants, somewhat similar variations were noted. With a concentration of 0.1 oz. per cu. ft., cypress dust produced a pressure of 15 lb. per sq. in.; a mixture of poplar and cedar dust at the same concentration produced 23 lb. pressure; and a mixture of tupelo and sweet gum under the same conditions gave a pressure of 22 lb. per sq. in. In the tests of oak, cedar, and mixed hardwood dusts, concentrations of 0.2 oz. per cu. ft. were used, and the pressures produced were 25 lb. for oak, 26 lb. for cedar, and 25 lb. for the mixed hardwood. These figures are cited not so much to draw a comparison between different wood dusts as to show the wide variation in the results. If any comparison can be drawn it is that the softwoods as a rule produce higher pressures than the hardwoods when the concentration is low, but as the concentration increases the pressures increase more rapidly for hardwood than for softwood. Of

---

[1] Engineer, Chemical Engineering Division, Bureau of Chemistry and Soils, U. S. Department of Agriculture. Mr. Brown was born in Williamsburg, Pa., on May 11, 1895. He studied flour-mill engineering and was graduated from the Pennsylvania State College in 1916. An advanced technical degree was conferred by the same school in January, 1923. Since 1917 he has served the U. S. Government in the development of methods of preventing dust explosions in industrial plants. During the War Emergency Campaign he was in charge of the Eastern District and served in the same capacity during the dust-explosion prevention campaign of the U. S. Grain Corporation. He has served as a representative of the U. S. Department of Agriculture on various committees and organizations, such as the American Standards Association, National Fire Protection Association, and the National Fire Waste Council of the U. S. Chamber of Commerce. Mr. Brown developed the method of using flue gas for the prevention of dust explosions in feed-grinding systems and is the author of a number of articles on dust explosions, their characteristics, and methods of prevention.

Contributed by the Safety Committee and presented at the Annual Meeting, New York, N. Y., Dec. 1 to 5, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

the most importance, however, particularly to the operator of a woodworking plant, is the fact that all of the wood dusts tested have been found to be quite explosive, which indicates very conclusively the necessity for the adoption of explosion-prevention measures. Before considering some of the preventive measures recommended it may be well to review briefly some of the explosions investigated in which certain outstanding facts indicate quite definitely the methods to be followed in reducing or eliminating the dust-explosion hazard in woodworking plants.

Explosions Investigated

A short time ago a serious dust explosion occurred in a woodworking plant in the Middle West where the shavings and dust

Fig. 1 Concrete and Steel Will Not Withstand the Pressures Produced in Dust Explosions

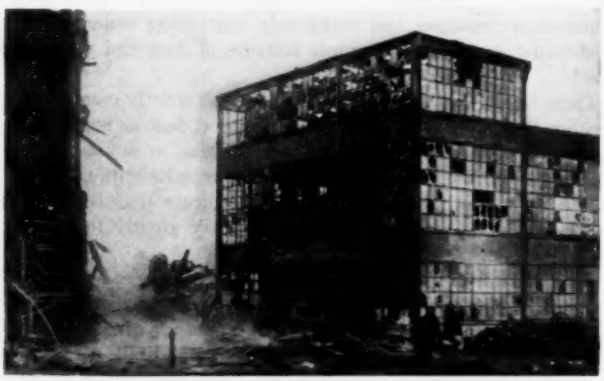

Fig. 2 A Building That Survived a Dust Explosion
(Large window areas and light wall and roof construction frequently serve as vents to release the pressure of a dust explosion and to prevent serious damage.)

from the finishing machines were deposited in a brick vault extending from the boiler room through the various floors to the roof of the plant. This vault 22 ft. by 37 ft. and 35 ft. high with 8-in. walls extended 6 ft. above the building and was covered with a flat wooden roof. Two metal cyclone dust collectors were supported by a steel framework directly over the vault and discharged the material they received from the machines through the wooden roof into the vault. Material was removed from the vault through three doors at the bottom located about 8 ft. from the furnace doors. Fire is believed to have entered the vault through one of these doors, although sparks or a smoldering fire may have been carried with the material blown into the vault from the plant. When the fire was discovered two men went to the roof of the plant and attempted to open a 2 ft. by 3 ft. door in one end of the vault. An explosion occurred instantly, and the men were buried under bricks and debris. Flames shot out of the vault openings in the boiler room and enveloped three employees there. The force of the explosion was sufficient to lift the vault roof and the heavy steel framework which supported the two cyclone collectors, and the entire mass dropped into the vault.

Previous explosions are believed to have been caused by backdrafts from the firebox of boilers, and there is also a case on record where a spark from an emery wheel near a woodfinishing machine ignited the dust, and the fire was drawn into the dust-collecting systems. In another case a bolt dropped into the cutters of a grinding machine and produced a shower of sparks which ignited the finely divided dust in the air.

One of the explosions reported occurred under peculiar circumstances. Oil and sawdust on a bearing caught fire and ignited sawdust on the floor below. In an effort to extinguish the blaze the assistant engineer dashed a pail of water on the floor with such force that some of the light dust was thrown into suspension and exploded.

A somewhat similar explosion but on a much larger scale occurred at the woodworking plant where the scrap, shavings, and

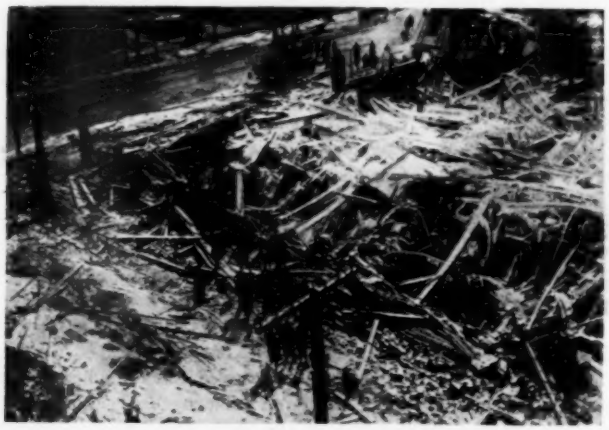

Fig. 3 Result of a Dust Explosion in a Woodworking Plant

sawdust were passed through a hog and blown to a storage tank outside of the boiler house from which it could be drawn as needed for boiler fuel. A fire at the hog flashed through the pipe line and ignited the material in the storage tank. Firemen attempted to draw off the contents and wet it down with a hose as it fell from the tank to the ground. The dust cloud formed in this way was ignited when the burning scrap fell from the tank, and the resulting explosion enveloped and seriously burned several of the firemen. Soon after this explosion firemen attempted to draw off the contents of interior bins following a fire in a Western woodworking plant, and six of them were killed when the dust cloud thus formed ignited and exploded.

Precautionary Measures

The information obtained in the laboratory tests of wood dust and during the inspection of woodworking plants indicates very clearly some of the precautionary measures which must be adopted in order to obtain protection against dust explosions. It is of course impossible to have a dust explosion without a sufficient quantity of dust in suspension in the air and a spark or flame to ignite the dust. As in all other dusty industries, therefore, cleanliness is of the utmost importance. If the plant is kept clean, there will be no dust to form a cloud through which an explosion can propagate, even if a minor

dust ignition should occur in or around one of the machines. Careful attention to the elimination of all possible sources of ignition, such as open flames, electrical apparatus likely to produce sparks or arcs, cutting or welding torches, and exposed element electrical-heating devices, will also serve to reduce the dust-explosion hazard. It has been found possible to produce a dust explosion by breaking in a dust cloud a lighted incandescent electric lamp. Evidently the filament remains heated after the glass is broken for a sufficiently long interval to ignite the dust particles with which it comes in contact. It is essential, therefore, to provide double globes and guards for all lamps of this kind used in a dusty atmosphere.

Steps should be taken to prevent the accumulation of static electricity on machines or equipment, because some dusts can be ignited by static sparks. Metallic sparks also are likely to cause trouble, and magnetic separators should be installed wherever necessary to prevent foreign material entering grinders or other machines.

Special care should be taken to prevent hot bearings or friction of belts and moving machinery which may cause a fire or dust ignition. Fire-resistive construction should be used wherever possible, and automatic or self-venting windows often prove valuable in releasing, before serious damage can be done, the pressure produced in a dust explosion.

Safety Codes

The precautionary measures which have been mentioned are the ones more generally applicable to the average plant. Complete safety codes for the prevention of dust explosions in grain elevators, flour and feed mills, sugar and cocoa plants, starch factories, and pulverized-fuel systems have been prepared by the National Fire Protection Association through its Dust Explosion Hazards Committee and have been approved by the American Standards Association. A special study of dust control in grain elevators has been made by the Chemical Engineering Division of the Bureau of Chemistry and Soils, and the results, together with certain suggested changes in the design and installation of dust-collecting systems, have been published in U. S. Department of Agriculture Bulletin 1373.

Regulations for the prevention of dust explosions in wood-flour manufacturing establishments have been tentatively adopted by the National Fire Protection Association, and attention is being given to safety requirements for other types of woodworking plants. It is suggested that owners or operators of woodworking plants obtain a copy of either the tentative code or one of the completed codes and consider carefully the safety requirements. Undoubtedly many of the recommendations in the completed codes can be followed or adapted to use in plants where wood dust is present and will serve to reduce considerably the dust explosion hazard. The Chemical Engineering Division of the Bureau of Chemistry and Soils in the U. S. Department of Agriculture will furnish on request any information on dust-explosion prevention which is available for distribution.

Discussion

H. G. Wiberg.[2] The data made available by the author draws attention to a hazard in woodworking plants not commonly thought of or known. The information should be utilized to prevent explosions similar to those cited from occurring in other plants. However it is thought that additional information which may in fact be already available, but which is not given in the paper, will be necessary.

The results of tests with respect to the pressure resulting from the explosion of different kinds of woods and at various concentrations are mentioned. It is wondered whether any data indicating the necessary concentration of wood dust to create an explosive mixture are available. Have any tests of that sort been made? Does this vary with the kind of wood and the fineness of the dust?

In discussing the explosions investigated, no mention is made of the products being manufactured. Were the plants sawmills, veneer plants, furniture mills, cabinet works, piano factories, planing mills, or sash and door plants? Fine dust is found only in certain types of woodworking plants, and we can therefore exclude a great many plants from this discussion.

For instance, the writer has been in a great number of planing mills, sawmills, sash and door plants, carpentry and cabinet shops, wood-turning plants, veneer product and cooperage shops where there were open flames, sparks of various kinds, and bearings and shaftings coated with sawdust and dripping with oil. They had been that way for long periods. He personally has not heard of a dust explosion in this type of plant.

Are not the explosive conditions confined to plants where work involving a large amount of fine sawing and sanding is found, such as furniture, radio-cabinet, piano, and panel factories? And perhaps the size of the plant has some bearing.

It seems that the efficiency of blower systems, where large quantities of fine wood dust are made in the process of manufacture, has a distinct bearing on the problem. If the suction is adequate and the heads closely surround the cutter or abrasive tool, there will be little free dust around the machines. This does not mean, of course, that the precautionary measures cited by the author should be disregarded, but that efficient dust removal will minimize, if not obviate, the hazard in the workroom.

The paper points to the conclusion that the great hazard is at the storage vault, tank, or cyclone. The writer does not note any specific recommendations for prevention at that source. Perhaps there are none. Has that phase been investigated?

A word with respect to the health hazard in woodworking plants. The writer cannot recall any claims for compensation because of work in an atmosphere which we might say is full of dust. There are few such places, anyway. As a rule, where there is a quantity of really fine wood dust coming from machines, it is kept down by dust removal systems. On the other hand, the writer has been in many places where the air was full of coarse wood particles and has not come across any cases of disease as a result. Apparently, the ordinary nasal dust-removal equipment takes care of that type and prevents injury.

The writer is reminded in this connection of a paper at a session of the woodworking section of the National Safety Council on infection from wood. The medical director of a large plant in Wisconsin, where there is a great deal of woodworking, made a positive statement that infection is not caused by any property of any kind of wood. Where infection follows puncture of the skin by splinters or any other form of wood, it is caused by some foreign material either being carried by the wood or present on the skin at the point of entry.

E. H. Schurch.[3] At the George W. Smith Woodworking Company's plant in Philadelphia, we have installed an Allington-Curtis screw-feed shaving stoker to handle hog refuse, shavings, and sawdust from the various machines. This consists of a small collector mounted above a storage bin on the roof of the boiler house. In the bottom of this storage bin are four screws which convey the fuel to two openings at one end of the bin. At this point, the fuel drops into the feeder screws, which are

[2] Lumber Mutual Casualty Insurance Company, New York, N. Y.

[3] Plant Engineer, Geo. W. Smith Woodworking Co., Philadelphia, Pa.

about 5 or 6 ft. in length, terminating in an almost vertical cylindrical chute which conveys the fuel into the furnace.

These screws are about 14 in. in diameter, and have a clearance of about 1/4 in. in the cylinder, which is supposed to prevent any fire from getting back into the storage bin. At the upper end of this vertical chute, there is an opening almost equal to the area of the chute, the idea of this being to admit a down draft into the furnace and prevent a flareback. At our request, this opening was closed with a loose hinged lid.

Since closing this opening we have had three fires, two of which were confined to the feed screw, but the other got up into the storage bin, which was hot enough to buckle some light iron sheets.

The question in mind is why, with all these screws agitating the fuel and no doubt keeping a lot of dust in suspension, was there not an explosion when the fire got into the bin. Mr. Brown's answer is that we did not get just the right condition or mixture to cause an explosion. In other words, we were just lucky that time.

This dust-explosion talk has thrown such a scare into us that we have installed steam jets in the openings from the bin to the feed screws and also in the bin itself. We wish to be just a little safer next time, in addition to being just lucky.

The writer also asked Mr. Brown if there was any danger from sparks in the case of a large collector which was dusting freely, located close to the railroad. His answer is that there was a possibility of an explosion, but he did not consider it very serious.

Author's Closure

Mr. Wiberg's question concerning the concentration of dust necessary to create an explosive mixture is one which several investigators have attempted to answer, and the results obtained in their experiments vary widely. The best information available indicates that to produce a wood-dust explosion it is necessary to have at least 10 oz. of dust per 1000 cu. ft. of air. This minimum concentration or lower limit cannot be taken as the absolute limit for such dusts wherever they are created because of the possible variation in size and composition under different manufacturing conditions, but it may be used as a guide in developing or providing dust-control equipment. One of the weak points in any work done with dusts lies in the inability to create and maintain a uniformly concentrated dust-air mixture. The heat capacity of the ignition source also has a decided effect on the limit.

In view of the laboratory tests referred to, it is believed that the lower limit of concentration for softwoods will be lower than that for hardwoods, but the figure given, 10 oz. per 1000 cu. ft., should serve for all practical purposes as the lower limit for wood dust.

Among the more than 70 wood-dust explosion reports in our files will be found listed nearly all types of woodworking plants, although it is generally specified that the dust producing the original ignition was fine. The greater number of explosions have occurred in sash and door plants, cabinet shops, wood-flour plants, or other establishments where fine dust is generally present, but sometimes ignitions occur in sawmills or planing mills when fine dust allowed to collect on overhead ledges is thrown into suspension and ignited.

Once a flame reaches the vault or shaving bin an explosion usually occurs unless the blowers have been shut down and the vault is comparatively free of suspended dust. Steam jets and water sprays are sometimes used to reduce the hazard at such places, but the method generally followed is to endeavor to provide protection rather than means of prevention. In bins properly vented with loose covers or swinging doors in the ratio of 1 sq. ft. for each 80 cu. ft. of volume, destructive pressures cannot be produced by an ordinary dust ignition.

The dust-ignition problem mentioned by Mr. Schurch is one generally encountered wherever an attempt is made to feed log refuse, shavings, and sawdust to the firebox of a boiler. Some success has been attained in preventing ignitions due to back drafts by installing steam jets or sprays. A system of chokes or dampers designed to prevent the passage of a flame will be found much more satisfactory, it is believed. Chokes may be produced in screw conveyors by removing a section of flights usually for a distance equal to about three times the diameter of the screw and substituting pins for the flights. This arrangement forms a seal in the conveyor box by allowing material to accumulate. The pins prevent packing, and the oncoming material forces that ahead of it through the choked section. Seals of this kind will prevent flashes or back drafts from the boiler reaching the storage bin, but care should be taken in shutting down to see that the material in the choke is not burning and the damper in the feed line to the boiler is closed.

Revolving dampers or rotary feeders are proving satisfactory in many instances as a means of preventing flames from the boiler reaching the storage vault. They consist of a paddle wheel or star wheel revolving horizontally, inside a close fitting cylinder with openings at the top and bottom. Material entering at the top falls between two of the paddles or blades and is carried around as the wheel revolves until it reaches the lower opening, through which it drops. The object with all such devices is to prevent the forming of a flue or direct opening from the boiler firebox to the vault.

Study in Present-Day Wood Finishing

By H. A. DERR,[1] MARIETTA, OHIO

A specific case of wood finishing is described in detail, a type of plywood floor covering that is completely finished by the manufacturer, the operations being carried out while the flooring is continuously conveyed. The finish (a water-resisting coating applied to the under side of the flooring and a filler, two coats of lacquer, and a coat of wax applied to the face of the flooring) is completed in approximately two hours.

THE general matter of the technology of wood finishes and their application has been ably discussed in the sessions of this division, notably by Silverstein[2,3] and by Kennedy[4] in papers that have covered in considerable detail the characteristics of various wood finishes, particular attention being given to types of materials and methods of application then in current use.

It is the purpose of this paper to present a description of a specific case of present-day wood finishing, illustrating what may be accomplished through the coordination of the woodworker and the wood finisher and utilizing materials and facilities available.

The case cited is a type of plywood flooring completely finished by the manufacturer, the operations being carried out while the flooring is continuously conveyed and with the finish (a water-resisting coating applied to the under side of the flooring and a filler, two coats of lacquer, and a coat of wax applied to the face of the flooring) completed in approximately two hours.

This product and its process of manufacture are considered unique, particularly in that the development is the result of intensive research, with the project carried from inception to large-scale production in less than one year. In this development, certain important fundamental conditions contributed largely, as follows:

(1) An unusual opportunity was presented for cooperation between woodworker, equipment manufacturers, and finishing-material supplier, complete coordination of all effort being effected by an engineer familiar with plywood manufacture.

(2) No existing organization, equipment, or traditional technique for finishing the product was required to be incorporated or accommodated.

(3) The development of the finish was put in the hands of one manufacturer of finishing materials, thereby providing the most favorable conditions for the proper interrelation of all finishing materials.

(4) The quality of the woodwork delivered to the fitnishin department is of the highest order, thereby minimizing he surgfacing operations during finishing. The excellence of the woodworking was favored by expert assistance in applying the principles of flooring manufacture to plywood construction.

(5) Adequate financial resources and other facilities were available to carry out the research and development.

From the standpoint of finishing, the problem presented was as follows:

(*A*) To determine the most suitable and practical type of finish for prefinished plywood flooring.

(*B*) To develop such finishing materials as would accomplish the desired type of finish in the shortest time and with minimum operations.

(*C*) To determine the most favorable methods of application and to adapt the finishing materials to such application, making proper adjustments to conform with conditions imposed by continuous movement of the flooring during finishing and in large-scale operations.

A—Type of Finish

The plywood to be finished was for the most part faced with sawn white oak in strips, with considerable strip flooring faced with rotary-cut white oak or sawn red oak, as well as parquetry of plain or quartered white oak and to a minor degree parquetry involving walnut, mahogany, and maple, singly or in combination, and also a small proportion of maple strip flooring.

Practically every type of finish available was given consideration. With the oak flooring as the product of primary importance, finishing materials most suitable for that wood were selected first. Naturally the matter of color required early attention. A light antique oak color was tentatively selected. Its general popularity being later confirmed by an expansive survey of representative architects, home owners, etc., it was decided to standardize on it for all regular work on oak. Color combinations for the other woods were later worked out, using modifications of the finishing materials selected for the oak.

It was then determined that the desired color effect could be produced on the oak by a combined stain and filler. The type of finishing coat, however, involved careful consideration and investigation. The flooring manufacturer naturally desired as highly finished a floor as was compatible with the practical requirements. The aim was to standardize upon one finish, of the type which would appeal to the majority of buyers. This condition tended to eliminate the thin, "hungry looking" type of treatment which purposely leaves little or no protective film of finishing material over the surface, however desirable this might be from an artistic standpoint, particularly where antique effects are desired.

It therefore became apparent that a full-bodied, smooth coating with subdued gloss was desirable. To produce such an effect became the next step. Various varnishes and lacquers and shel-

lac were tested to determine what type and combination would develop the most durable and practical coatings.

The service to which a floor is subjected is of the most severe type, involving the tread of feet, scuffing from the movement of furniture, abrasion of hard particles carried in, exposure to water in small quantities, and occasional spillage of various liquids.

The floor finish must be hard, tough, and resistant to abrasion and water, but it should not be unyielding. Theoretically, the floor coating should be neither harder nor softer than the flooring, but should as nearly as possible become a part of the floor itself, so that when the floor is dented, the finish should not shatter or crack visibly nor should the finish leave the wood at the dented area, but rather it should follow the depression in the wood without loosening of the bond between the finish and wood.

It was determined by tests for wearing properties, exposure to the weather, and immersion in water that oak flooring coated with certain lacquers or varnishes offered the best general service, particularly if there also was applied a coat of wax. Sections of oak flooring finished in various ways were laid in passages or stairways. Stair treads offer a particularly rapid means of determining the relative wearing properties of flooring treatments. The earlier wearing tests were of this type. A device recently developed, best described as a twin-step testing machine, reproduces the average human step, successively applying pressure of 25 lb. per sq. in. through a leather pad which is turned 5 deg. at each step. Two samples can be compared side by side.

Although certain varnishes would make possible a high-quality finish at relatively low material cost, there was the considerable handicap of a comparatively long drying schedule, even with the fastest type of synthetic-resin varnishes. As it was planned to use a continuously moving conveyor for the flooring during finishing, it would be more economical to use a somewhat higher cost finishing material, particularly when lacquer offered other distinct advantages.

The type of finish finally selected resolved itself into the following: For the face of the oak flooring, a combination filler, two coats of lacquer, and one coat of wax; for the back or underneath side of the flooring, one coat of a water-resistant, rapid-drying synthetic-resin varnish carrying aluminum bronze, so as to develop proper leafing and coverage and giving a high degree of protection.

The decision as to the finishing materials for the face of the floor has been confirmed by an investigation, results of which were published in June, 1931, as circular No. 384 of the Scientific Section, Educational Bureau, American Paint and Varnish Manufacturers Association, entitled "Finishes for Oak Floors." The conclusions are in part as follows:

(1) It would appear that wax-like materials applied directly to oak flooring give entirely unsatisfactory service, in that they become dark very rapidly, allowing the dirt to become ground directly into the grain of the wood in such a way that it is very difficult to remove such dirt.

(2) It would appear that of all the finishing tests the ones which gave the best general results, resistance to grinding of dirt into the wood, the lightest in color and the best general appearance, were those in which the wood was first filled with silica wood filler and then given several coats of varnish, shellac, or lacquer.

(3) We believe that it is advisable that shellac, lacquer, or varnish finishes on floors be waxed before the floors are put into service and that wax coatings should be renewed frequently. The wax acts as a lubricant, protecting the finish from scratching. It is probable that a floor thus finished would remain in a presentable condition indefinitely if properly cared for.

B—Finishing Materials

With the general type of finish clearly defined, development work on the finishes took the form of producing materials which would, without impairing the high quality of the finish, make possible the minimum of time for the finishing. The several finishing materials adopted and the minimum time allowance for each coating are as follows: Combination filler, 30 minutes; first-coat lacquer, 20 minutes to permit sanding; second-coat lacquer, 20 minutes; wax, 6 minutes; aluminum backing, 10 minutes. The backing was applied prior to finishing operations on the face of the flooring, giving longer opportunity for drying. The actual drying schedule established in production is somewhat slower than the foregoing allowances. All of the drying operations are assisted by temperatures ranging up to 134 deg. fahr. (See Table 1.)

It is probably desirable at this point to give attention to each of the finishing materials involved.

Combination Filler. By this is meant a material which fills the pores of the wood and at the same time introduces the desired color into the finish. In many cases a considerable depth of color can be introduced into the wood, but in this instance the staining effect required is relatively slight. The development of a combination filler to meet the unusual requirements for speed of drying was difficult. In the building of a wood finish the foundation is important. This foundation in the finishing of oak, which presents large, open pores, is the filler. After it has been properly packed into position, it should harden without shrinking or swelling, bringing the surface of the wood to a uniform level and providing a smooth, non-porous surface that will permit of building up other coatings until the full finish is produced.

TABLE 1 FINISHING SCHEDULE FOR PREFINISHED PLYWOOD FLOORING (SEE FIG. 1)

(Conveyor Moving Continuously at Rate of 14¼ Ft. per Min.)

1	Loading on conveyor in woodworking department.
Aluminum backing (total time 11½ min.):	
2	Sprayed on back of flooring.
3	Force-dried at 130 deg. fahr. for 1½ min.
A	Air-dried at room temperature for 2½ min.
B	Force-dried at 134 deg. fahr. (relative humidity, 46 per cent) for 6 min.
4	Flooring turned back-side down.
A	Air-dried at room temperature for 1½ min.
Filler (44½ min.):	
5	Brushed on face of flooring.
6	Flatted by air-blast from fan (room temperature) for 2 min.
7	Padded-in by 26-in. Strand rubbing machine.
8	Rubbed-off by hand after ½ min.
A	Air-dried at room temperature for 1 min.
B	Force-dried at 134 deg. fahr. (relative humidity, 46 per cent) for 39½ min.
9	Cooled by air-blast from fan (room temperature) for 1½ min.
First-Coat Lacquer (34½ min.):	
10	Sprayed on.
A	Air-dried at room temperature for 5 min.
C	Force-dried at 104 deg. fahr. for 6 min.
D	Force-dried at room temperature in chamber providing rapid air circulation for 11½ min.
A	Air-dried at room temperature for 1½ min.
11	Sanded.
A	Air-dried at room temperature for 3 min.
D	Force-dried at room temperature for 6 min.
A	Air-dried at room temperature for 1½ min.
Second-Coat Lacquer (25½ min.):	
12	Sprayed on.
A	Air-dried at room temperature for 4½ min.
C	Force-dried at 104 deg. fahr. for 6 min.
D	Force-dried at room temperature for 12 min.
A	Air-dried at room temperature for 3 min.
Wax (8 min.):	
13	Padded-on.
14	Rubbed-off after 1 min.
15	Polished after 1 min.
A	Air-dried at room temperature for 6 min.
16	Removed from conveyor for inspection and packing.

Total time for complete finishing, 2 hr. 4 min.
Total time for complete cycle of conveyor, 2 hr. 12½ min.

By ordinary standards a good filler should be hard enough in from 24 to 48 hours to permit the application of lacquer finishing coats, assuming normal room temperature. For many years the 24-hour drying schedule had been in effect when varnish-type coatings were to be applied over the filler, and with the advent of lacquer finishing coats, it was for a while felt necessary to permit a drying period of 48 hours to offset the softening action

to be expected from lacquer coatings involving liquids of high solvent power.

It having been tentatively determined that a force-drying condition with a temperature ranging from 130 to 140 deg. fahr. would be feasible for the work proposed, experimental work which had been under way on this general type of filler for some three years was directed at this specific problem, and a filler was finally developed which could be coated over with lacquer materials within 30 minutes after completion of the filling operation when assisted by a force-drying condition of rapid air circulation at a temperature from 130 to 140 deg. fahr. and with a relative humidity of approximately 45 per cent. This same filler when air-dried at normal room temperature takes lacquer coatings properly within $1^1/_2$ hours. To provide a liberal factor of safety, the process finally set up provided for a force-drying period of $39^1/_2$ minutes, or a total of less than 45 minutes for the time required from the first operation in the application of the filler until the lacquer coat was applied over the filled work.

Prior to the development of this filler, it is believed that the most rapid-drying practical filler available was that used by a large radio-cabinet manufacturer, in whose process the wood filler is air-dried for $2^1/_2$ hours.

To make possible this drastic reduction in the time schedule no sacrifice of practical working properties or quality was involved, as indeed this filler has proved to be remarkably adaptable, particularly as to what may be done with it in the manipulation of the initial set-up immediately following the application of the filler.

The filler, supplied in paste form, is thinned with benzine in the proportion of 7 lb. of filler to 1 gal. of benzine. In this thin consistency it is brushed upon the surface of the wood. Evaporation of the volatile material immediately begins, and when this has developed to where the surface of the filled work "flats down," the filler is "padded in" by rubbing across the grain. In the process finally established only two minutes elapses between the application of the filler and the "padding in" process, during which time the work is under an air blast from a fan. It was found, however, that the same filler, if properly adjusted, could be passed through a dry room at 130 deg. fahr. for six minutes before "padding in" and still work properly.

In a wood filler there are four different types of materials usually involved. The "backbone" of the filler consists of inert pigment of transparent type; then there is the binder, which causes the hardening action; other materials are used to introduce the desired color, and volatile liquids are used for thinning the paste to proper working consistency.

While a filler is ordinarily rather simple in its chemical composition, the filler required in this case is quite complex. In the same four types of materials, 23 different materials are included; 8 come as raw materials to the filler manufacturer, while 15 are more or less highly processed before fit for use. The bulk of inert transparent pigment used is finely powdered silica, but two other inert pigments are used in combination with silica. The binder used in this filler differs radically from that usually employed in wood fillers. Ordinarily, raw linseed oil with a proportion of drier is utilized. However, this case, in order to make possible hard drying in the minimum time while retaining proper working qualities, required the development of a highly processed oil combination in which a certain balance of materials is carefully adjusted.

The coloring materials used are for the most part natural earth pigments, to avoid the tendency of the lacquer solvents toward "bleeding" of the color. The dyes also are of a special type.

The volatile portion of the filler comprises petroleum and coal-tar distillates balanced to give the desired speed of initial set-up and final hard drying.

The results obtained with this filler are an indication that research has accomplished what was predicted by Silverstein,[3] that "a filler will be developed with a drying time which will more nearly approach that of lacquer instead of the 48 hours now required."

Lacquer Facing Coater. Lacquer is not customarily used as a floor coating, primarily because of the difficulty in application by brushing and, secondarily, because the average lacquer is not suitable for floor treatment.

Prefinishing of the flooring overcomes the first difficulty, and the great diversity of materials which scientific research has recently made available to the lacquer manufacturer makes possible lacquers that are entirely practical for use on floors, giving great durability and introducing into the floor finish at the same time qualities which are peculiar to lacquer.

A lacquer for use on wood floors must provide for strong adhesion, and at the same time be sufficiently elastic or plastic to "stay with" the wood during volume changes due to varying humidity and also when the floor is dented in service.

Resistance of the flooring finish to weather exposure is also of importance, as during occasional exposure at open windows or doors. Practically any lacquer is highly resistant to the action of water on its finished surface, but only certain types of lacquers resist the action of moisture from beneath the film, i.e., moisture which finds its way into the grain of the wood under the finish, with resultant swelling of the wood and consequent strain upon the bond between the lacquer and the wood.

Such a condition, in an extreme degree, is represented by the immersion of wood coated on one face with lacquer, but with end grain or back of the wood, or both, unsealed. Therefore tests of this type with the finished flooring immersed in water for periods of 24 hours and longer were freely used in the development of the lacquer. Also, various types of weathering tests were utilized, in some of which the flooring under test was completely sealed with finishing coats, while in others only the face was sealed or finished.

In general, it was found that those lacquers that stood up the best in immersion tests also gave greatest durability under outside exposure to the weather. The weathering tests, however, are particularly important because of the action of the ultra-violet rays of sunlight.

The methods employed for testing the value of the lacquer with respect to wearing properties have already been described, and these wearing tests, immersion tests, and weathering tests constitute the most significant tests available, it being found that lacquers which satisfactorily answered these tests would, in general, meet other and special tests, such as exposure to sub-freezing temperatures, to soap solutions, brine, alcohol, gasoline, ink, and various commonly used medicinal preparations having staining or corrosive properties.

In the formulation of the lacquer it was necessary, also, to have the material properly adjusted for application to the filled work while the flooring retained a temperature of 125 to 130 deg. fahr., involving unusually slow set-up on the part of the lacquer in order to obtain a smoothly flowed finish.

Furthermore, the lacquer facing coater must permit sanding within a very few minutes after application of the first coat, and waxing in a similarly brief time after the application of the second coat, followed by packing in bundles, face to face and back to back, a little more than an hour after the application of the first coat of lacquer facing coater.

It was for a while considered necessary to use different lacquers for the first coat and second coats, but later, for several reasons of a practical nature having to do with the operation of the plant, it was decided that inasmuch as one lacquer could be developed which would meet all of the requirements for both first coat and

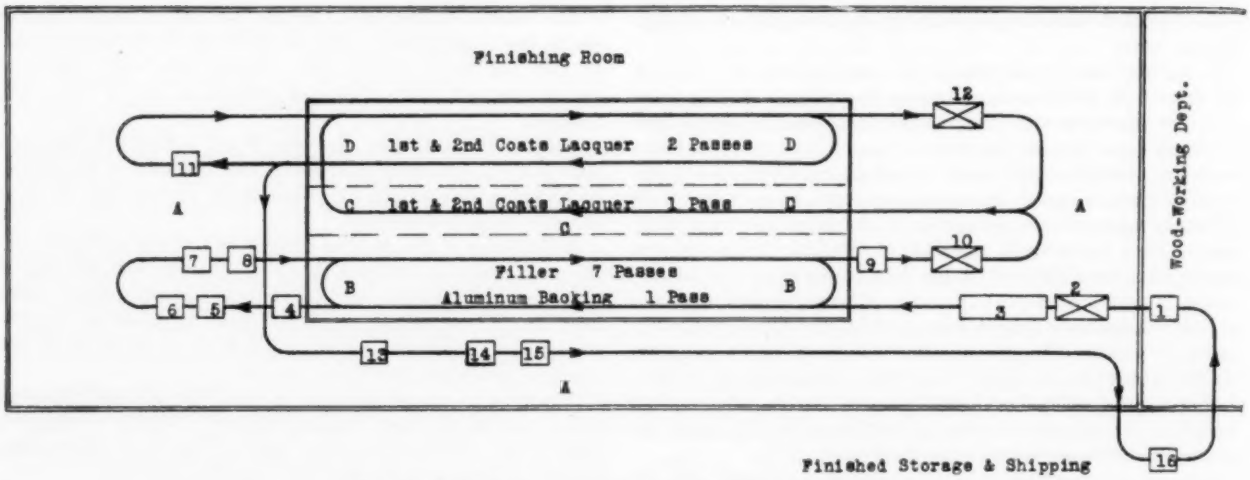

FIG. 1 CHART OF OPERATIONS ALONG CONVEYOR SYSTEM
(See Table 1 for key.)

second coat work, it was desirable to utilize only one lacquer.

The composition of a lacquer coating which complied with all these varied and more or less conflicting conditions is interesting from a technical standpoint, but it may be said that the development of such a lacquer has been made possible only through the utilization of a synthetic resin of a very unusual type in combination with a group of the most modern solvents, some of which have been available to the industry only during the past year or two. Nine different materials are involved in its make-up, all of which come as raw materials to the lacquer manufacturer, while each of these materials in itself represents the product of a more or less complex chemical process resulting from and controlled by applied organic chemistry of a high order.

Wax. The general popularity of a wax finish on hardwood floors is well-founded, because of the comparative ease with which this finish may be maintained or renewed, the upkeep of the floor being thereby simplified. At the same time, a beautiful, subdued sheen is developed upon the floor by repeated waxing, and this effect is reproduced on the prefinished flooring by the use of a coat of wax as the final finishing application. Another useful service which the wax coating performs is the protection of the finished faces of the flooring during storage and shipping, the wax acting as a lubricant, preventing slight marring as the result of the tight bundling of the strips in steel-strapped cartons and serving also to protect the face of the flooring during the laying operation.

The wax combination used, while polishing readily, is not slippery. The principal component of this wax is the time-tested beeswax, in combination with other waxes and suitable solvents.

Aluminum Backing. The use of an aluminum backing coat for the bottom side of the flooring tends toward an increase in cost over a clear or unpigmented backing coater, but the features of increased efficiency in moisture resistance and increased attractiveness of appearance justify its employment. Because of its lower cost a varnish-type vehicle, rather than lacquer-type, was selected.

The leafing action of aluminum bronze during the setting-up of the film makes possible the special efficiency in moisture-proofing attributed to aluminum coatings. This same characteristic tends to retard the drying of the vehicle. The development of a varnish-type vehicle for this purpose, which would comply with the extremely rapid drying schedule imposed and offer a very high degree of moisture resistance, represented a most interesting problem from the standpoint of its technology. The back or underneath side of the flooring is coated as the very first operation in finishing. Within ten minutes the aluminum coating must be set sufficiently hard to permit handling, as the flooring is at that stage of the process turned over on the conveyor. While the aluminum backing coater continues to dry and harden during the finishing of the face of the flooring, it is only two hours and four minutes from the time the aluminum backing coater is applied until it may be packed in bundles for shipment.

The vehicle portion of the aluminum backing coater is a striking example of what can be accomplished by the new technique in varnish making, and its composition is an illustration of the so-called synthetic varnish. Representing a synthetic resin of highly complex origin (phenolic-condensation product of the bakelite type) properly cooked with china-wood, or tung, oil, with the addition of suitable metallic driers and volatile thinners, there is presented a varnish which gives not only the desired speed of drying, toughness, and water resistance, but a full-bodied film meeting all of the practical requirements of a one-coat sealing and protecting finish on the under side of the flooring.

This entire finish represents a further interesting illustration of the interdependence involved in modern industrial civilization. The four different items of finishing materials supplied by the manufacturer of finishing materials to the woodworker in this instance represent a total of 48 different materials which, coming as raw materials into the processes of the maker of finishing materials, are in many cases themselves the highly processed products of the chemical industries, which in turn draw upon the natural resources of widely separated parts of the world.

This may also serve to illustrate the importance of the interrelation of one finishing material to another and the advisability of obtaining when possible all finishing materials from one source to insure the proper correlation of the various finishing materials; which point is of greatest importance when for any reason a change becomes necessary in any one of the coatings.

C—METHODS OF APPLICATION

Let it be kept in mind that the application of all finishing materials was required to be done while the flooring is in constant motion, and with the flooring temporarily assembled to form panels 24 inches wide (the width of four strips) and 80 inches long, the panels supported by standard carriers coupled to the conveyor chain. This condition naturally influenced the selection of methods of application.

The aluminum backing coater and both the first and second

coats of the lacquer facing coater are applied by spraying, hand operated.

The filler is applied by brushing, "padded in" by a machine consisting of a rotating disk 26 inches in diameter, equipped with a series of felt pads as rubbing members, as shown in Fig. 2, and is rubbed off by hand.

Owing to the high degree of perfection of surfacing and smooth-

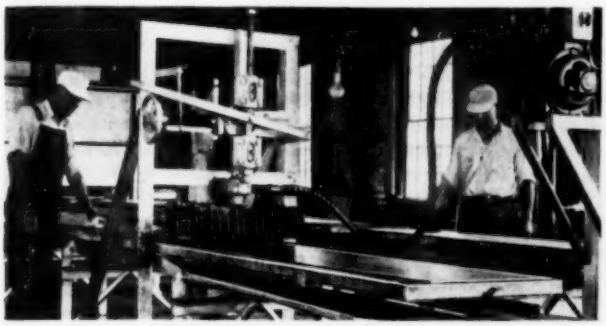

FIG. 2 APPLYING THE FILLER

(Showing where filler is applied and intermediate sanding and rubbing is done.)

ing operations on the flooring before its entry into the finishing room, only one slight hand-sanding operation, supplied by one man, is required during the finishing operations. (See Fig. 4.)

The wax is padded on, rubbed off, and polished at the present time by hand. These operations can, however, all readily be accomplished mechanically.

It was recognized that spraying application, particularly of the lacquer coats, involves the waste of considerable material in excess of that actually falling upon the work, as well as the use of a large proportion of volatile material which serves only to spread the solid content of the lacquer into place and is then lost by evaporation; and serious consideration was given to the possi-

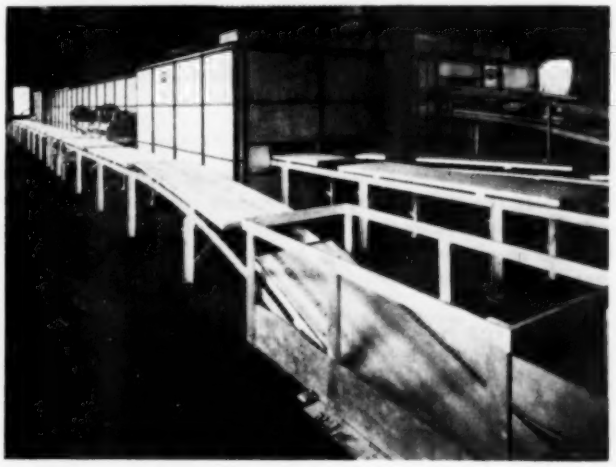

FIG. 5 FINISHED FLOORING ON CONVEYOR TO THE PACKAGING DEPARTMENT AND STOCK ROOM

bility of application by rolling, which process permits of the use of heavier bodied or higher non-volatile content material. Such application, however, was deemed not as practical as spraying for the purpose at hand.

In the final adjustment of finishing material to meet the actual conditions involved in the large-scale production process, surprisingly few and slight changes were required to be made in materials previously developed and tested in the laboratory. This is to be attributed largely to the full cooperation and complete exchange of information between the flooring manufacturer, the manufacturer of equipment, and the manufacturer of the wood-finishing materials.

Operation of Finishing System

Figs. 3, 4, and 5 show the general character of the equipment set-up. In the center of the large finishing room is built a drier system which includes three separate compartments, each with a separate air-circulating system and humidifier and automatic temperature control, heat being supplied by closed steam coils.

The conveyor is arranged to pass back and forth through the drier and extending a considerable distance beyond both ends of the drying chambers. All spraying operations are located at one end of the main room along the conveyor, while the filling and sanding operations are carried out at proper stations at the other end of the system. (See Fig. 1.)

One loop of the conveyor extends into an adjoining building in which the woodworking operations terminate, and here the conveyor is loaded with flooring ready to be finished. (At another point along this same loop the finished flooring is removed from the conveyor for inspection and packing.)

The flooring enters the finishing room back side up (see Fig. 3), and is temporarily assembled for finishing in panels. Moving continuously at the rate of $14^1/_4$ ft. per min., it is finished as described in detail in Table 1.

In this process the product being finished is not withdrawn at any time from the conveyor line, there being no provision made for the semi-processed product being accumulated in pools or side streams as in some other wood-finishing operations which make more or less use of chain production methods. As the result, there is no flooring in evidence in the finishing department except that which is actually in movement at all times, the amount of product being held at any time in semi-processed condition being governed simply by the capacity of the conveyor.

Conclusion

Distinct advances have been made in the art and science of wood finishing during very recent years.

The application of scientific research based on long experience in practical wood finishing and utilizing improved types of materials now available make possible the development of high-quality finishes on wood in a fraction of the time formerly required.

Complete cooperation between manufacturer of woodwork and manufacturer of wood-finishing materials, with proper coordination of knowledge and effort, has been demonstrated to bring a prompt solution to a difficult and unique problem in wood finishing.

Such coordinated effort, applied according to sound scientific principles and making use of modern mechanical equipment, has resulted in the development of schedules for the finishing of wood comparable in speed of operation and uniformity of product with those in effect for metal finishing.

Such finishing schedules do not necessarily involve any sacrifice whatever in the quality of the wood finish, as wood-finishing materials available today which can be adapted to such rapid schedules make possible finishes of higher quality than have heretofore been possible or economically practical.

"Science can, and will, help the woodworking industries, particularly in the application of cheaper and more durable materials. The extent to which science can be of assistance depends largely on the attitude and cooperation of the woodworker."[2]

WDI-53-11

Utilization of Wood Waste in the Chemical Industries

By BEN B. FOGLER,[1] CAMBRIDGE, MASS.

The principal uses, other than for fuel, for the wastes from the sawmill and woodworking industries are found in the following chemical industries: Destructive distillation, the manufacture of pulp, paper, and building boards, and those industries consuming large quantities of wood flour, principally linoleum, plastics, and explosives. The technical aspects of this waste utilization have been so satisfactorily worked out that a project of this sort may be evaluated almost entirely from the economic side. Competition from other raw materials, together with certain economic factors, requires that all of these operations be based on an ample, well-located, and relatively long-lived supply of waste wood. In many of these processes the waste wood must be separated either as to size or as to variety, although in some cases similar varieties may be processed together.

Bachrach

THIS paper is intended to present a comparative summary of the several outlets which the chemical industries afford for the salvage of waste from the woodworking industries. The discussion is limited to those processes in which the immediate conversion of the waste or its ultimate utilization fall within the so-called chemical industries. It is, however, true that, except for fuel and the limited market for the disposal of these wastes in the form in which they are produced, the chemical industries afford the only outlets which have been developed on a substantial scale for waste of this nature.

Consideration is similarly being restricted to those developments in which the technical aspects have been satisfactorily worked out, both as regards procedure and the details of commercial equipment, so that such economic factors as the supply of waste, the cost of conversion, and the possibility of profitably distributing the finished product are the determining factors in such a venture. In view of the importance of the economic aspects of this situation and the fact that these vary so widely from case to case, no attempt will be made to set up over-all cost data on any of these processes, although an effort will be made to discuss the relation of the more important factors in each process as a guide to the consideration of any individual case.

As determined by the limitations noted, the processes considered are those for the manufacture of the following materials:

Wood flour
Wood distillation products
Pulp and paper products
Building board.

From an economic viewpoint, there are a number of common elements in these conversions which, to avoid duplication, will be considered at this time and then referred to only briefly in the detailed discussion of each process. On account of existing competition all of these operations must be carried out on a comparatively large scale. It is essential, therefore, that a careful check be made of the supply of raw material and the cost of getting it to a central processing point. Consideration must also be given to the uniformity in the quality of the material as regards species of wood, as well as to the continuity of volume throughout the year.

Most of these processes involve a substantial investment in equipment, some of it having a comparatively long life; and the analysis of the supply of wood waste should establish its availability over a period to amortize properly the capital investment in the waste plant. This is particularly true in those operations where the finished product is in competition with an essentially similar product made from other raw materials or from new wood.

As regards the cost of conversion, the usual economic factors apply, although there is frequently an available supply of excess or low-cost power about such primary woodworking operations.

The problem of profitably distributing the finished product is one of the most important phases of such a venture. With the possible exception of building board made from the waste from sawmill or wood-dressing operations, the product of such a salvage project will be distributed through entirely different channels from those in which the basic product of the parent company is sold. The parent company entering upon the manufacture of such a by-product is therefore usually faced with the alternatives either of marketing its product through a sales agent or of setting up a separate sales organization for the distribution. The cost of such an organization, and also that of the supervisory personnel and other elements of fixed overhead in the by-product plant, are among the most important factors in determining the scale upon which an enterprise of this sort must be operated.

Another closely related phase of this general situation is the matter of choice as to whether the producer of the waste shall undertake its conversion to by-products or turn this work over to another group. The latter may be an organization subsidiary to, and jointly financed by, a group of several independent mills operating in a territory from which the waste may be economically collected and forwarded to a central point for processing.

Alternately, an entirely independent operator may purchase the mill waste as a raw material for his manufacturing operations. In this case the operator is in the position of setting up a secondary operation based on a primary one which he does

---

[1] Mechanical Engineer, Arthur D. Little, Inc. Mem. A.S.M.E. Mr. Fogler has had a long experience, having served three years in general mill engineering work; seven years in charge of production engineering, Ludlow Mfg. Associates, Ludlow, Mass.; two years in charge of mechanical research, Research Division, Chemical Warfare Service, Washington, D. C.; four years as mechanical engineer, Experimental Engineering Department, National Lamp Works, General Electric Company, Cleveland, Ohio; and five years with his present connection.

Presented at the Fifth National Wood Industries Meeting, New York, N. Y., Oct. 16 and 17, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

not control, and if he is wise, he will not confine himself to a single source of supply.

Careful consideration should be given to the location of the source of wood waste with reference to the markets in which the proposed salvage products are to be consumed. Neither wood waste nor the majority of products made directly from it in appreciable volume are of sufficient value per unit of weight to bear the cost of rail transportation to far-distant markets. This situation will effectively shut out many wood-waste salvage operations as long as there are adequate sources of similar waste more advantageously located with respect to markets in which the products of these operations are consumed.

Wood Flour

Wood flour is wood reduced to a fineness approximating that of cereal flours. It may be made of either hard or soft wood in any form, from the bolts of new wood from which some special flours are ground, to sawdust and shavings which serve as the raw material for the majority of the domestic flours. Much of the equipment in this industry follows cereal mill practice, both in the grinding and final sizing operations.

One of the major items of cost in the manufacture of wood flour is the power required in the grinding operation. An obvious economy in this direction is the use as raw material of wood waste in as finely subdivided form as is available in the requisite quantities. For this reason shavings and sawdust are preferred raw materials and are used in the manufacture of most of the flour produced in this country.

Although accurate detailed data are not available on the production and consumption of wood flour, a conservative estimate places the total quantity used last year at 85,000,000 lb., of which some 15,000,000 lb. are imports mainly from Germany and the Scandinavian countries, whose low production costs and cheap ocean transportation to our Atlantic seaboard permit their product to compete with domestic flour on a price basis in some of the important consuming centers in spite of a duty of 33½%.

Approximately half of the wood flour consumed in this country is used as a filler in the manufacture of linoleum. While ground cork was originally used for this purpose and is still preferred in some grades, such as battleship and the darker inlaid and jaspé patterns, on account of its superior resiliency, the lighter color of wood flour, permitting pigmentation through a wide range, makes it a more satisfactory filler for those patterns in which light colors and delicate shades are desired.

Explosives of the type of dynamite account for a third quarter of the total demand for wood flour. Here it is used, along with oxidizing agents, such as sodium and ammonium nitrate, to serve as an absorbent and to cut down the sensitivity of nitroglycerin and to produce an explosive which can safely be accepted for transportation by the common carriers. Kieselguhr, a diatomaceous earth, was originally used for this purpose, although it is entirely inert in its chemical contribution to the reaction at the time of detonation. It has been found, however, that cellulosic fillers of the nature of wood flour not only serve a similar purpose, but also furnish carbon and hydrogen to react with the excess oxygen in the balance of the mixture, thus producing a more complete explosive reaction. The users of explosives have learned to associate light colors with fresh high-quality dynamite, which, in turn, has created a demand for light-colored flour for this market, although there is no reason chemically why a darker material would not serve the purpose equally well.

The third major outlet for wood flour is in plastics, where it again serves as a filler or body. This market now consumes close to 10,000 tons a year of the highest grade flour that is made in large quantities. The resinoid plastics of the type of Bakelite and Durez often contain up to 60 per cent by weight of flour, which has proved the most satisfactory all-purpose filler for such plastics and is used in approximately 90 per cent of the molding powder made.

The balance of the demand is split up between several varieties of relatively minor outlets, among which might be mentioned the surfacing of wall paper, the manufacture of incense, and as a cleaning agent for the finer grades of furs.

Quoted prices on wood flour range from $23 per ton for the coarser linoleum grades to $50 per ton for the finer grades used in resinoid plastics. Some special grades sell as high as $80 per ton. The possibility of converting wood waste, which in many instances is of value only as fuel to wood flour salable at the prices noted, is one which has been extremely attractive to many lumbering and woodworking interests. It is significant, however, that the ratio of failures to successes in the manufacture of this commodity has been extremely high.

There are several reasons for this situation. The first is the rigid specifications which have been laid down by the consuming industries covering the fineness of grinding, color, and the resin content of wood flour. Many of these specifications are technically sound; others have been drawn more or less arbitrarily, to insure a continuation of a material of a grade which has been found satisfactory to the consumer without regard to whether or not flour of some other specifications might serve his purpose equally well or even better. The result of these specifications, however, has been to restrict the raw material from which flour acceptable to the trade can be made to a relatively few species of wood which, in the main, must be kept entirely separate for each particular grade of flour. Fully 75 per cent of the flour made in this country is ground from white pine. Poplar, fir, maple, and birch are used for special grades.

In the majority of the products containing wood flour as a filler, the binder and other ingredients cost so much more per pound than the wood flour that the incentive to establish more competitive sources of flour supply is correspondingly lessened. At the present time the large producers and consumers of wood flour are both relatively few, and apparently are working in reasonable cooperation. This, with the balancing effect of foreign competition, creates a market situation into which it is rather difficult for a new producer to break.

In selecting a location for the manufacture of wood flour, consideration must be given to the costs of raw material, power, and transportation to market. While shavings or sawdust are usually cheap at the planing mill, the cost of freighting to a central flour plant, even within a few miles, results in appreciably more expensive raw material than when the flour plant receives its entire supply by conveyors from the planing mills.

The major factor affecting the demand for wood flour is the rapid growth of the plastics industry. This use calls for a high-grade, light-colored flour, finely and uniformly ground and conforming to close specifications as to resin content.

An independent wood-flour operation should not be set up on a scale of less than 10 to 15 tons of finished product. A plant of 5000 tons annual capacity involves capital charges approximating $50,000, and the nature of the industry requires a substantial amount of working capital.

Destructive Distillation

Technically the recovery of values from wood waste by destructive distillation is one of the most fascinating of the chemical salvage industries. No one who has seen the plant of this type operated by the Ford Motor Company at Iron Mountain, Mich., or the unusually complete educational model of this installa-

tion which has been exhibited so widely can fail to be impressed with the thoroughness with which these conversion processes have been worked out and the step up in value between the waste from the sawmill and wood-body plant and the extensive line of wood-distillation products and their derivatives produced in the Ford plant.

The destructive distillation of wood which today is practiced almost exclusively on hardwood consists essentially of two steps, carbonization and distillation. In the first operation wood is heated in closed retorts from which charcoal and crude pyroligneous acid are obtained, together with non-condensible gases, the latter of value only as a source of heat in the process. The charcoal from the retorts is cooled, graded for size, and except where the high proportion of fines necessitates a briquetting operation, this portion of the product is ready for the market. In the still house the crude pyroligneous acid is initially separated into acetic acid, crude methanol, and wood tar. The refining and conversion of these intermediate products varies with the individual plant, and any adequate discussion of them is beyond the scope of this paper.

The economic soundness of any wood-distillation project depends upon simultaneous satisfactory markets for its three major products:

Methanol
Acetic acid or calcium acetate
Charcoal.

While there are firmly established and increasing markets for both methanol and acetic acid, this situation itself has contributed largely to the development of synthetic processes for the manufacture of both products. Several of these processes are now in commercial production on a large scale, and their output is seriously affecting the price of these materials. The production of synthetic methanol, starting in this country in 1927, has so increased that in 1930 it will represent over one-third the domestic production, while in the same period the price has fallen off almost 50 per cent.

The increased demand for acetic acid and its derivatives caused by the rapid growth of the lacquer and rayon industries has been sufficient to absorb the synthetic production of these materials at satisfactory prices, until early this summer, when quotations on both acetic acid and acetate of lime broke sharply, following the announcement of the new plant of the Commercial Solvents Corporation for producing acetic acid by the fermentation of corncobs. The liquor used to feed the bacteria effecting this fermentation is a by-product of other large-scale operations of this company. The reported capacity of the initial unit of this installation is 5000 tons of acid per year.

With the falling off in the market for charcoal for metallurgical use, the finding of satisfactory outlets for this material is rapidly becoming a problem of specialty selling, on a commodity that will not bear heavy transportation expense.

This general market situation has kept the wood-distillation industry in a very disturbed condition for a period of several years. Improved processes and equipment and favorable outlets for their production, frequently in part within affiliated industries, have kept some of the larger plants operating at an apparent profit. The most important factor in maintaining the wood-distillation industry in a position to operate in competition with the synthetic products just noted is the development of processes for the recovery of acetic acid of required commercial grades directly from the still liquor without the intermediate production of calcium acetate.

The majority of the wood-distillation plants are operated mainly on cordwood cut for this purpose plus any sawmill edgings that are available within an economic shipping range. Where this process is operated largely on the waste from woodworking plants, such as furniture and body plants, special retorts must be used such as the Badger-Stafford continuous retort for block waste and the Seamen rotary retort for sawdust and shavings. Both equipment and operating costs for plants with retorts of these types are higher than in the case of plants operating on cordwood to the extent of wiping out a large part of the advantage in the cost of raw materials accruing from the use of waste wood. A wood-distillation plant involves an investment of $5000 to $7500 per ton of bone-dry waste treated per day, depending on the type of waste and the extent to which the intermediate products are refined. Under present conditions a plant of 75 to 100 tons input capacity per day is the smallest that should be considered.

Pulp and Paper Products

The utilization of waste coniferous woods in the manufacture of pulp and paper products has made rapid strides within the past five years. This period has brought into production approximately 12 mills, producing in the aggregate some 1500 tons of pulp daily from raw materials consisting largely of the waste from the lumbering operations on the Pacific Coast. This represents approximately 10 per cent of the domestic consumption of pulp, and the availability of this material at highly competitive prices along the Atlantic seaboard has caused radical changes in the manufacturing practice of many Eastern mills. The Western mills are making sulphite pulp from Western hemlock, while Douglas fir and Western pine waste are being converted by the kraft process. Similar kraft conversions based on waste from Southern pine sawmills have been in operation in the South for a longer period.

The conversion of waste soft woods of almost any variety to standard pulp and paper products is purely a problem in economics for which the following brief specification may be drawn:

"An adequate supply of waste wood of varieties sufficiently similar to cook together uniformly to support a plant of economic size over its normal life, so located that the combined manufacturing and distributing costs will permit the product to be delivered to the consumer at a price equal to and preferably below that of the competing product."

Under the present highly competitive conditions in the industry the minimum unit operation in either sulphite or sulphate pulp mills should have a capacity of 100 tons per day consuming the equivalent of, roughly, 200 cords of wood.

The commercial status of the manufacture of paper products from hardwood waste of the varieties which are milled in large quantities is less clearly defined. The difficulty of using these woods arises from the comparatively short length of the ultimate fibers, when these are separated by chemical cooking and fiberizing operations, which produces a pulp of low strength in comparison with that obtained from the coniferous woods.

Under the demand created by the recent and continuing rapid growth in the use of fiber shipping containers made from both corrugated and solid stock, so-called "semi-chemical" cooking processes have been developed for hardwood which hold a real promise of a more profitable utilization of waste trimmings from these varieties. The best known of these processes is the Forest Products semi-chemical cook.

So far the only strictly commercial development of this process has been the manufacture of paper for container stock from the spent chestnut chips left from the production of tannin extract. Several plants of this type are in commercial operation, and the development has brought about a marked change in the economic structure of the chestnut extract business.

Processes of this type, of which there are others under develop-

ment, can be successfully applied to the conversion of mixed hardwood waste to container stock wherever an adequate supply of such waste is advantageously located as regards manufacturing costs and proximity to markets. Yields by these cooking processes are substantially higher than from the conventional chemical cooks. There are a number of features which indicate the possibility of profitably converting hardwood in units of approximately half the size of those which can be economically operated by either the sulphate or sulphite processes. Such a hardwood conversion unit should have a minimum capacity of 50 tons of product per day and requires approximately 50 cords of wood.

Building Board

Another important outlet for wood waste is in the manufacture of building board, the use of which has increased in a spectacular way during the past few years. This material is now produced in a variety of forms ranging from the insulating boards of the types of Celotex, Masonite, and Insulite to the dense, almost synthetic wood, of which Prestwood is the outstanding example. New wood as well as such wastes as sulphite screenings and sugarcane bagasse now furnish a considerable proportion of the raw material for the present boards.

While the manufacturing processes for products of this type are somewhat restricted by active patents, they offer with the proper combination of industrial interests an exellent opportunity for the utilization of wood waste of practically all the varieties worked on a large scale. Such wastes, in fact, are now being utilized in a substantial amount of the present production by cooking processes similar to those already outlined.

At present prices this field offers an unusually attractive margin above the cost of production; and manufacturing facilities have had this stimulus for expansion over and beyond that created by a rapidly growing market. This situation, together with the wide range and large quantities of available waste or low cost material which can be converted to a satisfactory building board, is bringing about an expansion of the industry which is likely to result in overproduction with a corresponding break in prices and curtailing of profit.

A new process still in the development stage offers the possibility, with relatively minor changes in equipment, of changing a considerable portion of the waste of wood-dressing plants from shavings to a fibrous material which in turn can be converted by developed processes to a rigid insulating board.

Building board as well as many of the container products which can be made from waste wood are in most instances competitive with products made from wood. Regardless of its relative merits as compared with the earlier products made from virgin wood, these newer reworked or synthetic materials are now firmly established. An appreciation of this situation is already evidenced by several of the far-sighted interests in the lumber and woodworking industries which are arranging their manufacturing setup with such salvage operations in view.

Conclusions

Commercial processes are available for the conversion of the majority of the varieties of wood waste from either sawmill or woodworking industries to products for which there is an established market. Many of these processes require the separation of the waste wood by varieties, and sawdust and shavings require separate treatment and are usually used in the manufacture of other products than those which can be made advantageously from slab edging and trimmings.

On the majority of these waste-wood products existing competition is of such a nature that new enterprises must operate on a substantial scale and frequently involve an investment in the by-product plant approximating that in the primary operation.

Distribution costs of the finished by-product are a very important factor in the utilization of waste wood and may frequently bar out a development offering both a satisfactory supply of waste wood and low conversion cost.

Supplies of waste wood from a small operation, unless it is one of several producing the same type of waste within a small area, cannot as a rule be salvaged by processes of the type discussed. An increasing number of special developments are making profitable use of these smaller quantities of waste, although in most instances local conditions and merchandizing skill have been primary factors in the success of these operations.

Although the economic position of the major wood-waste salvage operations may be definitely established with relation to synthetic or other competitive processes on the basis of existing technology, this balance is continually being upset by the results of research work within these industries. This element is of importance as indicating for any enterprise of this sort the need for a very thorough analysis of each individual case at the outset of the undertaking and the provision for a qualified technical staff as an integral part of the business. For the same reason a conservative policy should be followed in setting up the depreciation periods for plant and equipment.

Discussion

Leon V. Quigley.[2] One should find good incentive in the numerous uses to which even waste wood is adapted. Mr. Fogler has epitomized nicely the economic factors involved in the establishment of a plant for wood-waste salvage or conversion. His indication of difference and diversity of marketing problems involved in the sale of primary products and by-products is brief but significant.

To the molder of plastics, particularly those of the Bakelite phenol-resinoid type, the term wood flour implies a filling substance. The term filler is, however, unfortunate, inasmuch as wood flour is not added to phenol resinoid to contribute to the weight or bulk of finished product. Neither does it represent an attempt to conserve on the amount of resinoid binder used. In phenol-resinoid material wood flour has two principal functions: (1) It contributes to the facility of molding—modifies favorably the flow properties, etc.; (2) it improves the property of shock resistance, yielding a molded part mechanically strong and tough, instead of one relatively fragile, which would result if the resinoid were used without reenforcement. Truly, wood flour had much better be called a reenforcing material than a filler.

Physically, the wood flour acts as an absorbent for the resinoid. While the analogy is imperfect, one might liken the function to that of a blotter absorbing ink. Wood flour serves as a carrying agent—a mass of fibrous material in which the initially liquid resinoid is dispersed.

The choice of wood is interesting, since all woods are not suited to provide commercial wood flour. In view of the remarks of Mr. Fogler, it will be realized that wood flour is a much more refined product than sawdust. It is unfortunate that many contributors to the literature have confused the two terms. Wood flour is pulverulent in a somewhat strict sense of the word, rather than granular or flocculent like sawdust. From the viewpoint of the plastics industry, it will be appreciated that a more nearly homogeneous molded product results from the use of wood flour than would be possible using ordinary sawdust. Preference rests with such woods as pine and spruce. Choice of wood depends directly on composition, chemical and

[2] Leon V. Quigley, Technical Editor, Bakelite Corporation, New York, N. Y.

physical. From the physical standpoint, hard woods are rejected in favor of soft because lower in absorptive power.

Texture, or the degree of fineness, is a property of especial importance. The finished molded unit must frequently be of good appearance, and to this end it is necessary that the wood flour fibers be entirely covered by penetration, or film, of resinoid, plus pigment or dyes which it embodies. An appreciable problem is to so adjust the fineness of the fiber that the flour incorporates itself unnoticeably in the molded piece, retaining nevertheless a microscopically fibrous texture, which will contribute to the molded product a degree of strength and toughness, which is more characteristic of fibers than of powders.

Author's Closure

One of the difficulties in preparing this paper has been the limited space which the author was forced to allot to each of the major utilizations of waste wood, any one of which might profitably be made the subject of a paper of the same length. Mr. Quigley's discussion has provided a valuable and much appreciated amplification of that part devoted to wood flour.

The term "filler," while thoroughly understood within the several plastics industries, is, as Mr. Quigley points out, a somewhat unfortunate designation for a very important element in the composition of a wide range of industrial plastics, as well as in the specific field of phenolic resins. While it is true that some of the materials classed as "fillers" are used primarily as diluents to reduce the cost of the plastic compound as a whole, in the majority of instances the proper selection of fillers, both as to material and physical specifications, enables the plastic technologist to tremendously extend the range of physical properties and appearance of the product available with a single resinous binder.

In the wood-flour industry the results of the careful work of research groups in the phenolic resin field, represented by Mr. Quigley, are found in the rigid specifications already noted for the molding grades of flour.

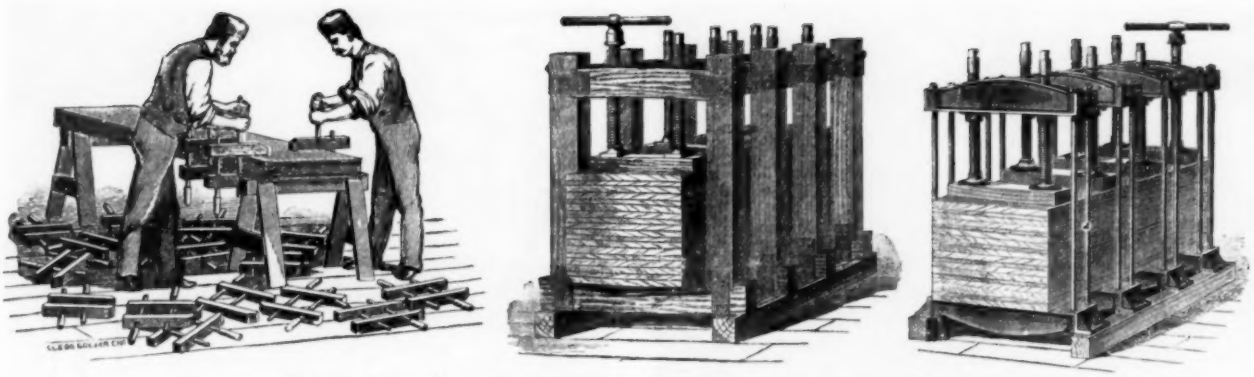

FIG. 1 HAND PRESSES, THE ANTECEDENTS OF THE HYDRAULIC PRESS
(Left, the age-old hand screw, applied to plywood; center, wooden-frame plywood presses, extensively used 30 years ago; right, iron or steel sectional presses, still used for hand work.)

Hydraulic Presses for Plywood

BY HARRY G. FRANCIS,[1] RUSHVILLE, IND.

The paper reviews the progress made in the clamping of plywood, especially in the last 35 years, when wooden hand screws and wooden-frame hand-screw presses were in general use. Improved hand clamps, improved hand-screw presses, and power-screw presses have their uses for certain classes of work and comparatively small output, and inverted-cylinder hydraulic presses are necessary for special methods and classes of work. Plywood is an artistic and utilitarian product with increasing appeal for both manufacturing and construction purposes. As the market for plywood products expands, new problems will necessitate further advances in press design. Plywood presses of the future may outdistance those of the present as much as the presses of the present demonstrate improvement over the old hand presses.

HISTORY relates that the earliest plywood press consisted of bags of hot sand, which both held the veneer flat against the core and accelerated the glue drying, and there is indisputable evidence of this process being used around 1500 B.C. Various other types of presses—lever, toggle-joint, and screw—came successively into use, but it was not until within the last 50 years that any standardized mechanical designs appeared. A few of the older designs are shown in the woodcuts reproduced in Fig. 1.

Though the hydraulic principle is one of the oldest and the most efficient methods of producing high pressure, its advantages in plywood gluing are not fully appreciated. This may be because so many inefficient hydraulic-press installations are still in service that plywood manufacturers are inclined to judge all hydraulic presses by these antiquated predecessors of the present-day high-production units.

HYDRAULIC PRESSURE IS MEASURABLE

Where pressures are to be closely regulated or a predetermined amount of pressure is to be applied, hydraulics must be used, being the only type of pressure that can be accurately measured and controlled. Until recent years, however, hydraulic presses as regularly furnished for the plywood factories were comparatively slow, although faster than hand-screw or power-screw presses. The pipe connections were not carefully made, methods of piston packing were not developed to the present-day efficiency, and the controls were not in the most convenient position.

MOTORIZED SCREW PRESSES

These apparent difficulties in the early types of hydraulic presses or the lack of intelligent operating methods led to further efforts to develop efficient mechanical presses. The most successful of these for plywood production is the screw type, as it can be made to operate at a proportionately faster speed, and when run by an electric motor, the pressure can be approximately gaged by an ammeter. This type of press is giving satisfaction where users do not require high or accurate pressures and the work is not of large area. When high pressures are required, however, the friction losses are excessive. A greater percentage of the power input is lost in friction, and as the friction losses are not in a constant proportion to the pressure exerted by the press, there is no way of knowing what part of the power input is being consumed by friction, and therefore no way of knowing what pressure is being applied to the work.

IMPROVEMENTS IN HYDRAULIC-PRESS DESIGN

In the meanwhile, development in the hydraulic field has been rapid, and the former objections to hydraulic presses have been eliminated. Methods of piston packing have been improved, pumping systems have been developed whereby any speed of operation can be had free from pulsation, and the controls are so simplified and protected that a child could operate them. The hydraulic press is built more compact than before; in fact, in many cases it is a self-contained unit requiring no more floor space than the press frame alone. A hydraulic press can be had to meet the most exacting requirements. There are a great many different styles and combinations, vertical and horizontal.

MODERN HYDRAULIC PRESS TYPES

The most popular of the modern hydraulic-press arrangements will be described. As different manufacturers use different trade

names and model numbers, the types will be described in details of construction and compared by key letters.

(*A*) *Press With Reciprocating Pump.* This is the most common form of hydraulic press (see Fig. 2) and has been built in this way for quite a number of years. This type is suitable where large production is not a problem and where large-dimension work is done to a limited extent and occasionally left in the press until the glue sets. It can be equipped with contact-making pressure gage, which can be set to start the pump motor when the pressure begins to drop and to stop it when the predetermined pressure is built up. This is an advantage over the older method, whereby the pump was left running continually against a relief valve, both in the saving in power consumption and in the wear on the pump.

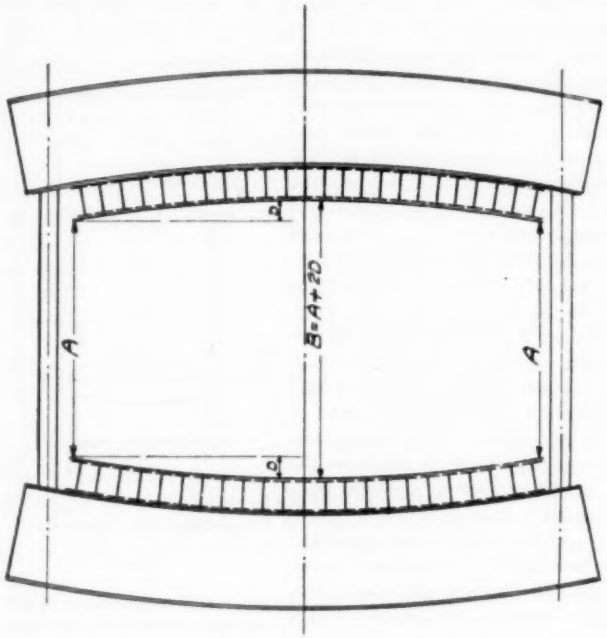

FIG. 7 STRAIN-ROD PRESSURES, WRONGLY APPLIED
(Side view, outside strain rods, platens supported at corners.)

(*B*) *Press With Reciprocating Pump and Motorized Rapid Traverse or Quick-Closing Head.* This type of press is similar to and has all of the advantages of the first-mentioned type, with the additional advantage of speed. The nuts on the top of the strain rods are in the form of gears, from which the top member of the press is suspended, as shown in Fig. 3. The internally threaded gears are motor-driven in unison through a connecting train of gears, making the top member quickly adjustable and enabling the operator to close the press on the work very rapidly, using the pump only for building up the final pressure.

This type of press combines all of the advantages of the power-screw type of press (not shown), with the superior pressure-applying qualities of the hydraulic press. It is suitable for large production, and usually has a closing speed of about 36 in. per min. When the plywood is laid up and the clamps are tightened, the pressure may be released through the motorized gear chain and the package removed immediately without waiting for the lower platen to return, as this platen (hydraulically operated) has not traveled very far in applying the final pressure.

This type of press is usually equipped so that the operation is semi-automatic; that is, when the plywood is placed in the press, the operator needs only to close the valve and press the "down" button of a three-button push-button station. The top member of the press will quickly run down until it comes in contact with the plywood. The pump will then automatically start to build up pressure, and the top will automatically stop. When ready to release the bale of plywood, the valve is opened and the "up" button is pressed. The pressure is thus released, and the top returns to normal open position and stops automatically. The normal open position is adjustable. Due to the short travel of the lower platen, no time is wasted in waiting for its return to unload, but there is still enough lower-platen travel to provide a platen-operated unloading device, the advantages of which will be described farther on. A greater variation in heights of packages can be handled without the use of fillers or without the use of extra-long hydraulic cylinder and ram, as the "daylight" (clear opening between platens) can be made to adjust from maximum to zero, and the adjustment for low packages can be made very rapidly.

Both the initial cost and the operating cost of this press are somewhat higher than with other types of production presses using hydraulic transmission throughout.

(*C*) *Press With Reciprocating High-Pressure Pump and Rotary Auxiliary Pump.* This combination is shown in Fig. 4 and embodies all of the advantages of type A, with additional improvements. It is also an efficient production press, as a rotary auxiliary pump can be had

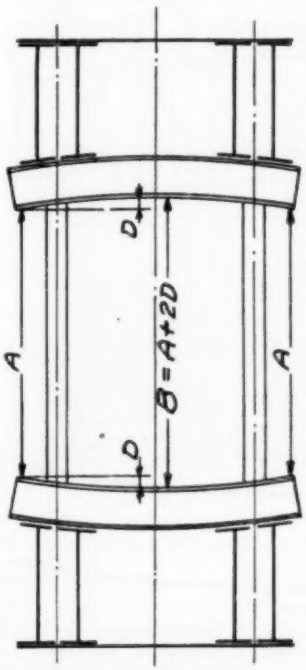

FIG. 8 STRAIN-ROD PRESSURES, WRONGLY APPLIED
(End view, outside strain rods, platens supported at corners.)

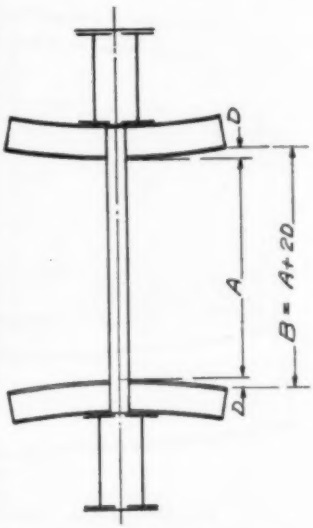

FIG. 9 STRAIN-ROD PRESSURES, WRONGLY APPLIED
(End view, center strain rods, with unsupported platen corners.)

that will effectively close the press at any desired speed. This press is also usually arranged with the semi-automatic control features, so that when the "up" button is pressed, the rotary-pump motor closes the press and takes up most of the slack in the package, building up initial pressure, which automatically, by means of a pressure-operated switch, causes the reciprocating-pump motor to start and the rotary-pump motor to stop. This arrangement makes this press with its two pumps as simple to operate as a press with a single pump. The number and kind of manual controls are the same.

It is not as expensive as type B, either in initial cost or in operation, as hydraulic transmission is used throughout. It is not as well suited to varying heights of packages as type B unless fitted with extra-long cylinder and ram. It can be provided with hand-adjustable "daylight," but this adjustment would require longer

time and would not be justified unless a fairly large number of the off-height packages were to be run. Although the closing speed can be made faster with this type than with the preceding, the lower platen must return the full travel distance before unloading, but return speed can be made as rapid as desired.

(*D*) *Press With Rotary Pump and Intensifier.* This is a smooth and quiet-operating combination, and is shown in Fig. 5. It is free from pulsation and shock. It closes at a high rate of speed and builds up pressure at a slower speed. When the pressure is building up, the gage finger moves steadily across the dial. The absence of pulsation and shock increases the life of the gage and of the valves and packings, and as there are but eleven motivated parts in the system, including the valves, a high efficiency is attained. A unit which exerts a pressure of 450 tons requires only a 3-hp. motor to operate it. As the pressure is built up steadily, perfect regulation can be had and it is simple to operate.

A valve and an electric push-button station are the only controls necessary, and it is usually equipped with a pressure-regulating gage that can be set to the pressure desired for each package before the "start" button is pressed, and when the

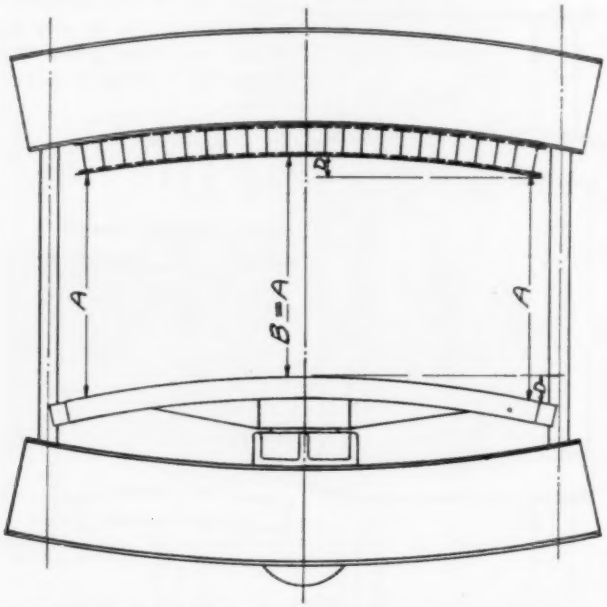

FIG. 10 STRAIN-ROD PRESSURES, CORRECTLY APPLIED
(Side view, outside strain rods, with center piston, showing both platens tending to curve in the same direction.)

pressure reaches the point for which the gage is set, it stops automatically.

SUMMARY OF OPERATING ADVANTAGES

The type D is the most economical press yet devised. Its operating cost is under that of any other type of power press, both in upkeep and power consumption. As all of the operating parts are built in the press frame with the exception of the intensifier, comparatively little floor space is required.

The four types of hydraulic presses described are the types now most generally used, and are all regularly built with an "up stroke;" that is, the cylinder is supported by the bottom frame and is arranged to apply pressure on the work through an upward movement of the ram. This arrangement is most desirable for plywood manufacture as it provides a means for more easily loading and unloading the press and is in other respects more desirable for plywood than inverted-cylinder presses.

RETAINER CLAMPING METHOD

As I-beam retaining clamps are in general use and are placed on the lower press plate previous to loading, the space between the clamp beams provides a convenient place for placing roller bars. These roller bars are made so that their overall height is slightly less than the height of the clamp beams, and when the press platen is raised in the pressing position, the roller bars rest on the face of the platen, and the clamp beams take the entire load. After pressing and tightening the clamps, the platen is lowered. At a point approximately a half-inch above the lowered position of the platen, the roller bars strike on jack stands, which cause them to remain stationary while the platen continues its downward stroke, thereby transferring the weight of the package from the platen to the roller bars. The package (shown in Fig. 6) can then be easily rolled out of the press over an offbearing truck and lowered to the truck by means of the jack stands. The jack stands are usually made to return to the starting or loading position automatically, leaving only the operation of lowering the package on the offbearing truck to manual control, and with the modern improvements, this operation consists of a pull of only 5 lb. on a hand or foot lever.

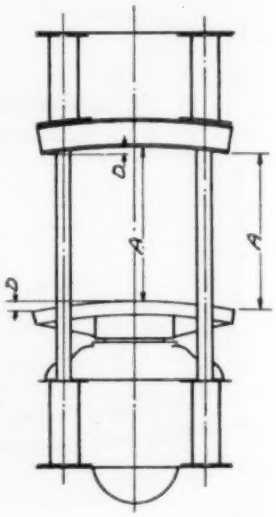

FIG. 11 STRAIN-ROD PRESSURES, CORRECTLY APPLIED
(End view of Fig. 10.)

PRESSURE-GAGE VARIATIONS

There is an impression among some users of pressing equipment in glue rooms that, when the pressure gage on a hydraulic press falls back, the press is losing pressure due to leaking in valves or packings. This is not necessarily the case. Any type of press, whether geared-screw or hydraulic, if provided with a gage to show the actual pressure held on a freshly glued package would show a drop in pressure. This is due mainly to the displacement of glue between the laminations and to a certain amount of compression in the stock, both of which actions continue after the press is stopped, causing the package to become lower and therefore to not offer as much resistance to the pressure applied. The same action takes place in all glue-room presses, but passes unnoticed in electrically gaged screw presses, as the electric gage or ammeter ceases to register as soon as the press movement is stopped, whereas the hydraulic gage registers as long as stock remains under pressure.

FRAME CONSTRUCTION AND PLATEN DESIGN

A feature of major importance in producing good glue joints in plywood manufacture is the method of constructing the frame of the press. The fact that the frame is heavily constructed does not necessarily mean that it is correctly constructed. Excessive deflection in a press frame may be the invisible cause of much spoiled work. It is impossible to build a press entirely free from deflection, but by means of proper construction and use of beams of sufficient depth, the amount of deflection can be minimized and its injurious effects on the work eliminated. There are shown three types of frame construction now in general use, with their deflection curves greatly exaggerated.

The front elevation of a press is shown in Fig. 7, with the pressure both applied and backed at the corners through the

strain rods. This type of construction, when the press is under load, permits the top and bottom members to deflect in opposite directions, causing more pressure to be exerted near the ends of the press than at the center in both directions across the press. This condition can cause a starved joint at the ends of the stock due to the concentrated pressure at this point, while at the center, part of the stock may not even be pressed into contact.

An end elevation of the same construction is shown in Fig. 8. While the same condition exists, it is usually to a much lesser extent, due to the shorter span. If deep presses for wide plywood are built in this manner, however, the deflection in this direction soon reaches serious proportions.

Fig. 7 also represents a front elevation of the type of press using only two strain rods, one at each end of the center. The same deflection curves apply to this press in this direction, and Fig. 9, which is an end elevation of this type of press, shows that under extreme load a large percentage of the pressure can be concentrated at the two points closest to the strain rods, as the deflection in both directions causes the members to curve away from each other in all directions radiating from the strain rods.

The front elevation of the usual method of constructing a hydraulic press is shown in Fig. 10. Although deflection cannot be wholly eliminated, the members for clamping the stock are made to deflect with each other instead of away from each other. This is due to the pressure being applied at the center and backed at the four corners, making it possible to hold the distance between the lower platen and the pressure head the same at all points, thereby delivering uniform pressure at all parts of the work.

An end elevation of the same press with practically the same conditions is shown in Fig. 11.

It is of course understood that the drawings show greatly exaggerated deflection curves, but if one considers a definite condition for an example, the importance of balanced deflection in press-frame construction can be more readily understood.

Let dimension *D*, Fig. 7, equal $^1/_8$ in. when under full-load pressure and *A* equal 30 in.; the *B* would equal 30 plus 2*D*, or $30^1/_4$ in. This means that the work under pressure must either be compressed $^1/_4$ in. more at the ends than at the center or that there is no pressure being applied at the center.

Compare this with a press constructed as shown in Fig. 10 with the same span and using the same members for the top, or in other words, with the same strength. *D* in this case would also equal $^1/_8$ in., and dimension *A* equals 30 in., and as the deflection of both pressure members is in the same direction, dimension *B* also equals 30 in., as well as all other points between the platen and the pressure head. This latter example cites a perfectly proportioned press, but even if the press is not perfectly proportioned, the greatest possible difference between the distances between the pressure members at different points could not possibly be so great as the total deflection of one member, whereas this difference in all other types of presses equals the sum of the total deflection of the top plus the total deflection of the bottom member.

Research in Wood Products

By JAMES W. LAWRIE,[1] MILWAUKEE, WIS.

Wood has widely different characteristics, and species may be chosen for a wide range of industrial and construction purposes possessing either high strength-weight ratios or qualities that permit cutting thin veneers, also possessing great ultimate strength or low specific gravity. It varies widely in color, grain structure, and beauty. Wood also has faults and limitations which can be largely corrected through intensive research. Wood expands when wet. Research with the X-ray has shown the reason, and has pointed to a way of rendering wood nearly non-expansive. Wood can be made fire-resistant, but tests must be conducted under both heat and strain conditions to be of practical value. Preventive measures can be taken to lengthen the life of wood by toxic-chemical treatments to eliminate decay. Wood-finishing methods can be greatly improved by scientific adaption of the right principles. There are many other wood qualities that can be improved by modern research methods.

IT IS VERY pleasing to know that the wood industries through the National Lumber Manufacturers' Association are organizing and equipping a research laboratory to undertake the study of wood. Of all the materials which nature has given us, wood was among the earliest used by man in construction work, yet through the ages man has neglected the study of wood and even today is largely in doubt as to what wood is, and why it has the peculiar and interesting physical and chemical properties which make it the indispensable material for variety, beauty, and practicability in construction.

Wide Range of Wood Properties

Wood has certain properties which can be evaluated. Pound for pound, wood, in general, is stronger than steel. It can be obtained in many sizes, in the form of veneer less than 0.01 in. in thickness, in lumber several feet thick, in lengths up to over 100 ft. These are woods that are soft, hard, that are lighter than cork, and heavier than water. Wood varies in color, grain, structure, and beauty. It is moderate in cost, generally available, and can be fitted and used by even unskilled workmen. There is some kind of wood that is useful and usable for almost every construction purpose.

Correcting Wood Faults

Has wood any faults which, if corrected or eliminated, would make it an even more desirable material? It is particularly along the lines of correcting the faults of wood that research should be of assistance to the wood producers and consumers. When wood takes up moisture it expands, when it is heated too highly it chars and burns, when rot fungi get proper conditions for attack they cause rotting, insects eat the wood, and lastly in order to keep the beauty of wood it must be protected from undue wearing.

Why Wood Expands and Contracts

What causes wood, a comparatively soft material, and water, a liquid, when brought together, to expand, and in expanding to exert such enormous forces as to be able to split open large rocks? In fact, the wet wedge is employed commercially to split marble, slate, and other like formations because the lines of splitting can be controlled by proper placement of the wedges. How can two such soft bodies when brought together exert these great forces? Soft wood, liquid water. It seemed that water might react chemically with the cellulose molecules of wood to form a hydrated cellulose with a larger molecule, and that the expansion in size of the molecule is the source of the forces which exist. How can this idea be proved or disproved? If one can prove that there is chemical union or disunion of cellulose and water to form a larger or smaller molecule, and that expansion or contraction is due to these reactions, then why can not the cellulose molecule unite with some other chemical than water to form a permanent union and thereby stabilize the wood so it will no longer contract or expand?

X-rays have been turned to as a means of answering the question as to what is the reaction between water and cellulose, and why are expansion and contraction practically all across the grain of the wood and almost none along the grain? The X-ray work was carried out by Dr. George L. Clark at the University of Illinois. He was able to show definitely that the swelling of wood is a physical and not a chemical reaction. The reason wood expands largely in one direction is that the cellulose in the form of large spiral crystals is packed in close bundles called micelles. Moisture as such cannot penetrate these bundles, but it does penetrate in between the bundles and by capillary force pushes the micelles apart with tremendous force. As the micelle bundles are long in the direction of the grain of the wood and very narrow across the grain the expansion takes place proportionately much more in the cross-grain than in the length. By X-rays it is possible to measure exactly the amount of expansion, the size of the micelles, the number of crystals of cellulose in a micelle, and further the number of molecules of cellulose in the crystals themselves. These established facts have been of great value in pointing out the direction of research to overcome the entrance of moisture between the micelles. Experimentally so far the rate of this entrance of moisture has been cut down to 10 per cent of that of untreated wood taken from the same board. The complete exclusion of moisture from the wood, however, is not looked forward to. Wood is now looked upon as a tank with a large capacity for quickly absorbing or giving up moisture. By use of proper moisture-resisting treatments the rate and to a lesser extent the amount of water or moisture which may penetrate into the wood is cut down, and in this way the wood is stabilized so that under ordinary average conditions there is such slow absorption or evaporation of moisture as not to affect expansion or contraction in wood with continuous changes in humidity. If today humidity is high and tomorrow

[1] Director of Chemical Research, A. O. Smith Corp. He received the degree of Ph.D. from the University of Chicago and was engaged as chief chemist for several manufacturing concerns from 1909 to 1919, when he became research and consulting chemist for the E. I. du Pont de Nemours and Co. He joined the A. O. Smith Corp. in 1930.

Contributed by the Wood Industries Division and presented at the Annual Meeting, New York, N. Y., Dec. 1, to 5, 1930, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

it is low, there will be no appreciable effect on the treated wood because of the slowness of the rate of absorption or evaporation of the moisture. Over long low humidity or long high humidity periods the contraction or expansion will change, but in considerably lesser total degree than for untreated wood. Apparently one can never hope for a complete freedom from expansion and contraction.

Fire-Resistant Wood

The problem of next greatest interest is probably that of making wood resistant to fire. Again it is realized that no treatment can make wood fireproof, but at best it can be made more or less resistant to fire. There are several factors that must be considered in the study of fire resistance. If wood is to be made only resistant to the passage of fire such as would be the case with partitions and separating walls, then this is a certain type of problem, but if it is to be made resistant to fire and at the same time is under a stress from a load such as is structural timber in a factory, then the question of the effect of the chemicals used in the treatment of the wood becomes at least of as great importance as does the problem of fire resistance. It has been found that many of the chemicals that are used to give wood resistance to burning react on the wood at not very high temperatures and cause a much more rapid destruction of the wood than does the fire itself, and the treated timbers will give way under their loads long before they would be consumed by the fire. This point should be given deep consideration, and methods of testing for fire resistance should at least, in the case of structural timbers, include definite tests on the effect of the chemicals on the wood at varying temperatures up to the ignition temperature. The use of salts soluble in water or aid in fire resistance is wrong in theory. Such salts in nearly every instance are injurious to the wood even at normal temperatures, and chemical action takes place even though very slowly. The salts also tend to leach out gradually or in some cases to volatilize, and therefore gradually render the wood less resistant to fire. Another undesirable feature is that wood treated with water-soluble salts must, in general, be first slowly air dried and later kiln dried, a time-consuming process, and because of time, requiring the carrying in stock of large quantities of treated wood in process.

Preventing Wood Decay

From the tree in the forest to the lumber bought is a pathway of waste and loss. Only about 40 per cent of the tree reaches the consumer. Further than this, the average life of the wood used for all-around construction purposes is only about 10 years. This means that much of the wood lasts only a short time to make up for that portion which lasts a long time. Wood properly taken care of should last for decades. Why the short average life? Wood is subject to attack by fungi which in their life process put out certain chemicals that react on wood to cause it to change in its physical as well as chemical properties. The effect of these changes we call rot. With rot fungi the old paint slogan, "Paint the surface and you save all," is an unhappy misnomer. Rot fungi can work from the inside of the wood out or from an unpainted surface like the back side of a base board through to the painted surface. Again, throughout most of this country and in all tropical countries the ravages of termites, the so-called white flying ants, are causing untold damage to both old and new wooden structures.

Toxics for making wood immune to rot and to attacks by termites and other wood-destroying insects must be toxic to fungi and insects, but should not be toxic to humans. They must be slightly soluble in water or in the liquids of the fungi or insects in order to act as a toxic to them. They should be odorless, practically colorless, should allow for the wood being painted, varnished, lacquered, or given some type of finish to enhance the beauty of permanence of the wood; they must be permanent and must not weaken the physical structure of the wood over a long period of time. Another desirable requirement is that they be easily applied without expensive equipment or the necessity of keeping large stocks of treated lumber on hand because of the long, slow period of drying as is the case when the wood is treated with water solutions of toxic materials. Again the wood should not undergo changes in dimensions due to the treatment, and where complete penetration is not required, the method of treatment should as far as possible sterilize the wood throughout. Where wood has been kiln dried complete sterilization is assured, and if the moisture content is held low then the inside of the wood should remain sterile after the outside is treated. Again, the concentration of toxic materials in the wood must be considerably greater than the "killing concentration" due to the gradual loss of toxic either by volatilization or solution from the wood. Finally, any successful treatment of wood from rot resistance must be reasonable in cost.

Better Finishing Processes

The beauty of wood can be preserved from damage or definite changes by coating its surface with materials which either are less affected by weather and abrasion or which can be readily applied to the surface, such as with varnishes, lacquers, or oils. With some woods the beauty is enhanced by the use of stains, which usually help differentiate the grain of the wood, by fillers which help level the surface, by varnishes, etc. which by differences in defraction bring out more markedly the beauty of wood. Hard woods such as red and white oak are used very extensively for floors. There are several fundamental reasons for the choice of these woods for flooring purposes. The woods are hard and therefore wear well, they have unusual variety and beauty in grain, they do not readily splinter or crack, and they can be easiest enhanced in beauty by varnishing or lacquering.

The problems presented in giving a desirable finish to oak flooring have not been given thorough study in all their aspects. The ordinary practice is to sand the floor, then add the filler coat with a certain amount of rubbing or brushing to remove excess filler. Next shellac, varnish, or lacquer is applied. In many instances the floor is considered as finished, but in some cases a second coat of varnish, etc. is applied and then a coat of wax which is given a so-called polish. The entire procedure is really, at least theoretically, incorrect.

Avoiding Sanding Errors

An analysis of the sanding operation shows that the surface of the wood is torn usually in one direction by means of abrasives. These abrasive materials are not uniform in size nor are they distributed on the sand belt or drum in an absolutely uniform manner. The result of sanding is that the surface of the wood is scored and pressed down in the direction of the movement of the sanding belt. When filler is then applied to such a surface it does not readily enter the open grain of the wood where the wood "whiskers" have been pressed into the grain. The result is that the filler cannot function properly and the average floor when finished presents a very uneven surface. In theory a floor should be given a currying so that the fibers are shredded, but not removed, and they should stand up giving a velvet-like appearance to the surface of the wood. The entire surface of the wood supporting the "whiskers" of the curried wood should be at a uniform level. The next operation should then be the shaving of the whiskers, leaving the surface of the wood level, smooth, and with no matted surface of finely shredded wood. The entire grain of the wood is left open. The appli-

cation of a proper kind of filler to such a surface is not sufficient, however, to insure good filling. The need for filling is to create not only a surface that is level, but also to create a surface which will allow a uniform penetration of the finishing coats of varnish, lacquer, etc. In order to get such a surface it is necessary to work the filler into the soft and open grain of the wood under a pressure which is just great enough to force the filler into the grain, but not great enough to abrade the harder structure of the wood. By the application of a filler that has the proper absorption qualities, and by the use of the required pressure, a surface is created which is entirely different from that of ordinary filled wood.

Wood Fillers

The proper filling of the wood is probably the most important step in the finishing of wood. It is the basic foundation of all the other materials to be applied. It gives a surface to the wood which is smooth and level, and as a result there are no multiplicity of small ridges such as result from the sanding process, and which have little resistance to abrasion. When abrasion starts at the peaks of these ridges, there is a rapid spread of destruction of the finish to large areas, but with the shaving method a surface is presented which is level throughout, and which wears evenly and therefore has a long life.

The question of the use of a seal coat directly after the filler has been the subject of much argument. Seal-coating materials have, in general, been made so as to give a film which has very little penetration into the wood, which is therefore somewhat brittle and subject to chipping by abrasion. The seal coat, however, gives a base for the subsequent finishing coats so that there is almost no penetration into the grain by the finishing coats, and therefore a more even surface is obtained, but they afford a poor surface for adherence of the finishing coats. With the very even surface presented by the newer method of surfacing and filling the wood, the old seal coats are unnecessary, but the use of a film which is intermediate in characteristics between the filled surface of the wood and the finishing coats gives a better set up than the use either of a seal coat or a first finishing coat. The final finish coat should be hard but not brittle. It will therefore stand abrasion well, and with a uniformly even foundation as presented by the previous finishes will wear several times as long as it would when applied under old conditions.

Prefinishing Flooring

The use of oak blocks set in a permanent mastic is rapidly coming into general use especially in homes, apartments, hotels, hospitals, etc. With a floor material of this kind, uniform in size, the prefinishing of the blocks in the factory becomes an interesting problem. It is at once obvious that the usual methods of finishing flooring would be impractical because of the long time period, and because of the very large space required for storage during processing. A study was made of the conditions which would be practical. This study showed that a time limit of two hours from raw to finished block was the maximum that could be allowed. To meet such time conditions it was necessary to develop more exact equipment and new methods of application of the finishing materials. There are no varnishes which will dry within these specified time limits. Lacquers were found not to wear satisfactorily, but with the cooperation of some of the lacquer manufacturers new lacquers were developed which present a hard surface, but which are not brittle. These lacquers age well and retain their hardness and non-brittle properties. With the use of the new methods of surfacing and filling, and the specially designed machinery, it is possible to finish the oak blocks in less than one hour. This finishing process includes surfacing, dust removal, filling, rubbing, removal of dust, first coat, drying, rubbing, second or finish coat, drying, rubbing, wax coat, and polishing.

How Floors Wear

The wear on floors is largely caused by persons walking over the floors. It is not, however, possible to make even fair comparative tests on various finishes on floors by counting the steps of persons walking over the floors. There is a tremendous variation in the weight, pressure, grinding effect of the persons, and in the particular spots where the walking dominates. The weather, dust, and a multitude of other conditions will all have their immeasurable effects. Because of these facts a "walking" machine was designed which gives a uniform pressure of 27 lb. per sq. in. to a disk of sole leather while turning 5 deg. in a circle at the time of contact with the surface. These conditions simulate average conditions of persons walking. The machine operates at the rate of 250 steps per minute, and the samples are run in duplicate, changing the two test pieces every 100,000 steps. Under the old conditions of finishing floors the finish with a good varnish will last for a maximum of 300,000 steps and with a lacquer for about 250,000 steps. With these same finishing materials, but applied by the new methods, the varnish and lacquer coats both stand up for over 1,500,000 steps. Obviously such a test is not quantitative. The wear of the finish is checked by microscopic examination and is therefore open to the error of personal equation, but the results are so outstanding that there is no question about the increased value due to the methods of application. The blocks finished by this method present a beauty which has heretofore been obtained only by the use of high gum varnishes and rubbing by hand.

It has been found, however, for stores, halls, or other places where there are unusual conditions that a polished floor is undesirable. In cases like this after the filler coat has been worked in, it has been found that the treating of the floors with a hot brushing of a solution of drying oils and waxes gives a splendid finish. This solution penetrates into the fibers of the wood and resists to a large degree the effect of moisture or water on the wood, it fills the cells preventing dirt and stain from entering, and it gives a finish that withstands abrasion and wear. It is particularly fine for use in smoking rooms where a varnish or lacquer finish is easily marred by burning cigarettes, etc. This kind of a finish is difficult to burn or char, and any discoloration is usually removed by a slight rubbing with steel wool and the application of some additional treatment.

Conclusion

The foregoing problems are only a few of the many which are apparent in the wood industry. As some measure of success is obtained with one problem other new and important problems suggest themselves. This is the history of research work on all other materials. It is well that it is already showing like history with regard to wood.

A.S.M.E. Record and Index, 1931

THIS section of the Transactions contains a record of the activities of The American Society of Mechanical Engineers for the year 1931, together with an index of its publications. It is issued to every member of the Society in pamphlet form and when bound with the technical papers of the Professional Divisions for the use of libraries and official depositories throughout the world, it completes the permanent record of the Society's activities.

The Record and Index Section of Transactions includes all the reference material likely to be of permanent value and of interest to future searchers. As an index it provides a means of locating the technical information in the Society's publications. It includes the separate indexes of the Transactions and *Mechanical Engineering*, together with a miscellaneous index to reports or other technical publications of the Society that have appeared during the year.

A considerable portion of the Record and Index is devoted to memorial notices of members who have died during the year. Special care has been given to the preparation of these brief biographies with the idea in mind that fitting attention should be given to significant events in the lives of deceased members, even though they may fall outside the immediate field of mechanical engineering.

ROY V. WRIGHT

PRESIDENT OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS
1930–1931

Roy V. Wright

AS railroad mechanical engineer and editor for the Simmons-Boardman Publishing Company, Roy V. Wright, president of The American Society of Mechanical Engineers for the term 1930–1931, has given more than thirty years of progressive service to the transportation industry.

Mr. Wright was born at Red Wing, Minn., on October 8, 1876. He attended the public schools of St. Paul, Minn., and the University of Minnesota, from which he received the degree of M.E. in 1898. He was given the honorary degree of Doctor of Engineering by Stevens Institute of Technology in 1931. He is a member of Sigma Xi and Pi Tau Sigma (1931).

Immediately upon graduation he entered the locomotive erecting shop of the Chicago, Milwaukee & St. Paul Railway at South Minneapolis, Minn., as machinist apprentice. For three years he served this railway and the Chicago Great Western as apprentice, draftsman, and chief draftsman. In 1901 he became mechanical engineer for the Pittsburgh & Lake Erie Railroad. This was in the period of early development of the all-steel gondola and hopper freight cars, the P. & L.E. R.R., in the heart of the coal and steel districts, being one of the first railroads to use such cars on a large scale. The locomotive repair shops at McKees Rocks, Pa., were also rebuilt during this period, involving one of the first extensive applications of individual motor drive to machine tools.

The editorial career of Mr. Wright began in 1904, as associate editor of the *American Engineer and Railroad Journal*, now *Railway Mechanical Engineer;* he was made editor of that publication in 1905. In 1910 he became mechanical department editor of the *Railway Age Gazette*, which is now *Railway Age*. In 1911 he was appointed managing editor of that publication, and this position and the editorship of the *Railway Mechanical Engineer*, which he resumed in 1912, he still holds. Since 1910 he has acted as editor of various editions of the Locomotive Cyclopedia, the Car Builders' Cyclopedia, and the Material Handling Cyclopedia. In 1911 he compiled and edited "Railway Shop Kinks" for the International Railway General Foremen's Association. Mr. Wright was elected a director of the Simmons-Boardman Publishing Company in 1915 and was appointed secretary four years later. In December, 1931, he was elected vice-president of the company.

He is also a director and secretary of the Simmons-Boardman Publishing Corporation and the board of the Y.M.C.A. of the Oranges; chairman of the Board of Publication and member of the Administrative, Railroad, and Industrial Com-

mittees of the Home Division of the National Council of the Y.M.C.A.; member of the International Committee of the Y.M.C.A.; trustee of the Silver Bay Association; member of the Silver Bay Human Relations in Industry Conference Committee; member of the board of the Committee on Friendly Relations Among Foreign Students; and a director of the Ampere Bank & Trust Co., East Orange, N.J.

He has been very active in the affairs of the A.S.M.E., which he joined in 1907. He was a member of its Railroad Committee before the formation of the Railroad Division, and a member of the first Metropolitan Section Committee. He served as manager from 1922 to 1925 and as vice-president in 1926 and 1927. He has been a member of the following committees: Meetings of the Society in New York, 1910–1914, and chairman in 1914; Railroad, 1913, 1914, 1915; Meetings and Program, 1919–1923, and chairman in 1921 and 1922; Policy of the Society, 1924; Presentation of Dues Increase, 1924; and Finance, 1926, 1927. From 1928 to 1931 he was a member of the Standing Committee on Awards; he is a member of the Biography Advisory Committee. He was president of the United Engineering Society during 1928 and 1929; was a member of the Committee on the War Memorial to American Engineers at Louvain, Belgium; was a delegate to the First World Power Conference in London in 1924, and honorary vice-president of the American Management Association in representing it at the International Management Congress in Prague, Czechoslovakia, in 1924. He was a member of the American Engineering Council committee which prepared the report on Storage of Industrial Coal, and is a member of the Advisory Board of the Department of Smoke Regulation of Hudson County, N.J. He was one of the organizers of the New York Business Papers Editorial Conference and served as its president in 1918. He is a member of The Franklin Institute, Engineers' Club (New York), Railroad Club of New York, and of the executive committee of the New York Railroad Club.

His contributions in papers and discussions have been an inspiration toward better engineering. He contributed a chapter on Transportation in the symposium "Toward Civilization," edited by Dr. Charles A. Beard and published in the spring of 1930, and he has delivered many addresses on this subject. He was one of the honorary editors of the Professional Divisions' reports on technical developments since 1880, as published in the Fiftieth Anniversary Issue of *Mechanical Engineering*.

The Engineer Militant[1]

By ROY V. WRIGHT

THE engineer has been subjected to harsh and severe criticism in these recent years. While much of this may not have been deserved, it promises to be helpful to the profession—strange as it may seem—if for no other reason than that it is forcing the engineer more thoroughly and critically to examine his part in and contribution to our economic program and progress. Moreover, it is encouraging him also to develop a larger and stronger professional consciousness. Again, it is a clear indication that certain elements, at least, are looking to him for leadership in helping to solve some of our more pressing economic problems.

These are trying days, and in some ways they promise to mark a distinct turning point in the activities of our Society, and in the emphasis on its major objectives. We seem to be at the parting of the ways. With statesmanlike vision and constructive effort we may yet lift the engineering profession to the heights which it should occupy, in the light of its past achievements and of the leadership which it can help to give this present civilization. Stuart Chase has been a harsh critic of the engineer, and yet in his "The Nemesis of American Business" he makes this statement: "Plato once called for philosopher kings. Today the greatest need in all this bewildered world is for philosopher engineers."

What About the Future?

Unfortunately, up to this time the engineer and those with whom he has been associated have been too prone to consider only the immediate results of their work, and have failed to vision the great forces which have been in process of development in our economic, social, and political life as a result of the complications brought about by this machine age, for which the engineer is largely responsible.

Was it a recognition of the engineer's responsibility in these respects that the artist attempted to portray so graphically on one side of the medal commemorating the Fiftieth Anniversary of our Society? Obviously the engineer pictured is looking over and beyond the tools and instruments in the foreground and is visualizing a world raised to higher levels and standards. Can the engineer render a larger or more important service than to insure the total results of his work, direct and indirect, being entirely in the interests of humanity? Those are indeed challenging words on the medal: "What Is Not Yet, May Be."

These problems and others have been brought home to me most forcefully as I have journeyed about among you this past year and have discussed with you some of the larger problems and challenges which are facing us. Quite naturally, therefore, there are a number of important tendencies concerning which I should like to talk with you this evening, if there were more time. I shall attempt rather to comment briefly upon only a few of the high spots.

Civic Responsibilities

We ought to give more serious consideration to the building up of a stronger professional consciousness, which will weld the engineers more closely together and inspire and encourage them to greater and more constructive unified efforts in the interests of humanity. Of all men the engineer should take a large and intelligent interest in helping to control all of the forces which have been set up as the result of our more complicated existence in this era of mass production. The very success of our nation depends upon the intelligence of its citizens and the extent to which they use this intelligence in working out problems of government—and these problems are steadily and rapidly becoming more serious.

Is it not strange, under these conditions, that students are being graduated from our colleges and universities, many of which are supported largely by public funds, without having any clear understanding of the elements of citizenship, or how they can best serve their communities and country? Engineers must take these responsibilities more seriously—as individual citizens or as groups in assisting their localities in city and county planning, or collectively by taking a larger part in public affairs of the state and nation.

We can, for instance, well take pride in and ought to support generously and with enthusiasm the work of the American Engineering Council, which represents the engineer in public affairs and has done so much also to bring the engineering attitude to bear in important economic studies. One of our members, L. P. Alford, was recently awarded the Gantt Medal, partly, at least, because of the outstanding part that he has taken in the making of these engineering economic studies in the public interest. Our President-Elect, Conrad N. Lauer, was mindful of the engineers' responsibility for public service when he founded the Hoover Medal, the purpose of which, in the words of President Hoover, "is to mark the public service of men who have gone outside their strictly professional work to interest themselves in civic and humanitarian affairs."

Elevating Professional Status

Study and discussion of the report on the status of the mechanical engineer, which was so ably prepared under the direction of a committee headed by President-Elect Lauer, indicate that there are possibilities of greatly improving the status of the engineer, which almost automatically should bring home to him more forcefully his responsibilities to the community at large.

If this is to be done thoroughly, however, it means a rebuilding of our structure from the very foundation. One of the evidences of an intelligent appreciation of this is the fact that more and more thought is being given to the better selection of young men who enter our engineering schools. In some instances members of the faculties of engineering colleges are getting in touch with the high-school authorities and are trying to locate, particularly through the science teachers, boys who seem to be particularly well adapted for engineering and who should be encouraged to enter that profession. Stevens Institute of Technology, under the direction of its president, Dr. Harvey N. Davis, also one of our vice-presidents, this last summer gathered a group of junior-high-school students at its camp in northern New Jersey, with a view to giving them a thorough understanding of what engineering is, and of the requirements for success in its various phases; at the same time an attempt was made scientifically to study and analyze each boy, with a view to encouraging those who were specially fitted for engineering to enter that profession.

Our Student Branches

Our Society has done good work with its Student Branches,

[1] Presidential Address, at the Annual Meeting, New York, N.Y., November 30 to December 4, 1931, of The American Society of Mechanical Engineers.

but has not approached the problem with the same type of statesmanship as in the supervision of the Local Sections and the Professional Divisions. The committee in charge of this work is to be congratulated upon the forward step that it is now taking. The experiment with the new set-up is at present confined to 15 Student Branches in the Southeast, but there are good reasons even now to believe that it will be a success and that, when extended to all of our Student Branches, it will more closely integrate the activities of our Society with the engineering colleges. Rightly directed, this means that it can be of very great assistance to the engineering faculties and students in a practical way, and will help greatly to develop a proper professional consciousness among the students; it should also, almost automatically, bring these young men into the membership of the Society. We have to too great an extent neglected these students. It will mean much to them if in the course of their training they can touch elbows with the experienced and practical engineer. Indeed, their future success depends largely upon the extent to which we reach out a helping hand to them.

The Junior Members

We have been so intent and so serious in promoting our technical programs that we have lost sight of some of the large opportunities for strengthening the Society and insuring its future stability. What, for instance, have we done in a constructive way to encourage and help the young graduate engineer? He needs our friendship as well as our helpful interest and encouragement. If he has come to our meetings, too frequently we have paid little or no attention to him, or have given him the cold shoulder. This neglect has not been intentional. We have simply failed to see the young man and to realize how much he needs coaching and encouragement; and too often we have lost him from our membership, possibly never to return. It is a question as to whether any other activity needs our attention so much at this time as the development of constructive and aggressive plans to assimilate the Juniors into our activities. They need us, but we need them with their youth, enthusiasm, aggressiveness, and courage. And then, too, this is one of the very foundation stones for building a larger and stronger professional consciousness.

Technical Meetings Cold and Inefficient

Engineers are not cold-blooded. Indeed, as we come to know each other as individuals, we find that we are intensely human. For some reason, however, our meetings have lacked much of that spirit of warmth and good-fellowship which is so vital if we are to come to understand each other better and to be mutually helpful to as great an extent as possible. Judging from numerous comments that I have received, many members fail to attend meetings because of the lack of this spirit. Some of our Local Sections are deliberately organizing to introduce a spirit of good-fellowship into their meetings.

We have been careless also in attending to the appointments and details which go to make the technical handling of the meetings a success. It is not enough to find some one who will prepare a paper or make an address, send out a formal notice to that effect, and then perfunctorily carry out the program. Staging a successful technical meeting is an art. Incidentally, even an experienced speaker has difficulty in overcoming some of the handicaps that are thoughtlessly placed in his way. Even a machine must be treated with reasonable consideration, but fine discrimination must be used with a human being if he is to give the best that is in him. Oh! how careless and thoughtless some of our members and groups can be—and never even realize it! Surely a profession that prides itself upon eliminating waste and increasing efficiency in industrial operations can master the technique of putting over successful technical programs.

We have not made the best of jobs in selling ourselves, either to the mechanical engineers who are not members of our Society or to the public. We can well take a lesson from the constructive piece of publicity work that has been done by the chemical engineers. Few things will do more to enhance our prestige or develop a larger professional consciousness than a carefully planned publicity campaign—and, personally, I believe this can well be done by the engineering societies jointly. It will cost money, but, wisely directed, should far more than pay for itself.

Engineers, Not Specialists

Up to this point I have carefully refrained from mentioning the mechanical engineer as such. Not that I am not proud of the profession and of this great Society which so ably represents it, with its multitudinous and far-flung activities. Basically however, we are engineers, having the same fundamental training and, in a large way, the same objectives as other branches of engineering. We are seeing recognition of this in the fact that engineering colleges more and more are thinking in terms of the engineer rather than of the specialist. We see it in the extent to which graduate engineers shift from one type of engineering to another. We see it in the tendency for specialized groups of engineers in a community to combine in federations or all-inclusive clubs, each type of engineering functioning as a group within the larger group. We see it again in the extent to which our national engineering societies more and more are engaging in joint activities—in technical meetings, in our Engineering Societies Library, in public service through the American Engineering Council, and now, let us hope, in a joint program looking toward the elevation of the status of the engineer.

Many years ago one of our most honored members, a past-president, Ambrose Swasey, made possible the formation of the Engineering Foundation. With clear vision and unfaltering step he has never lost faith in this joint activity for the promotion of engineering research. Within recent months he has generously added to his already liberal contribution to this project—a challenge to all of us to put forth greater efforts in this worthy joint activity.

Rapid shifts which have taken place in our industrial and economic life in this era of mass production have brought home to us in no uncertain manner the fact that the engineer must be so trained that he can readily adapt himself to new and greatly changed conditions. Indications are that such changes may be even more numerous and radical in the days to come. Just as business and industry should protect the worker by cooperation to provide a continuous training throughout his service life, in order that he may keep up with the advancement of skill in his craft, so the engineer must have a broad basic training in order that he may readily adjust himself to new and unforeseen requirements. This again emphasizes the fact that we should train engineers—not specialists.

Wanted—Militant Engineers!

Vice-President Ralph E. Flanders has recently published a book entitled, "Taming Our Machines." He is not a pessimist. Indeed, those of us who know him well have been impressed by his optimism and his enthuiastic, constructive attitude. He is a builder, not a wrecker. Listen to this challenge from the last chapter of his book:

> If our age of machines cannot assure, on the whole, a steady and considerable flow of sustenance and the opportunity for leisure for all who are able and willing to work, it has failed in the end which it was best adapted to serve. The whole social fabric built upon our machines will then slowly crumble and decay.
>
> The process of decay, however, will be hastened by direct attacks

which are being organized at this moment. The political battles of the present and future are visibly concentrating about our economic failures. If we, who are the sponsors of the machines and of the industrial society built upon them, can successfully organize them to the ends of general human satisfaction, and if we can join to ourselves the other groups whose cooperation is essential, or if we can join ourselves to them in some effective way, then this civilization which we have built will endure. Otherwise it will perish. No mere defensive tactics will avail in this critical undertaking.

Stuart Chase calls for philosopher engineers, but we need something more than this. We need militant engineers—aggressive and constructive—who will enthusiastically devote their energies to building up the engineering profession, raising it to higher levels, and will vigorously take the offensive in helping to find a solution of some of the great economic problems which we are now facing.

The American Society of Mechanical Engineers

THE personnel records and other information presented in this first section of the Record and Index refer, except where otherwise noted, as in the case of Local Section and Student Branch chairmen, to the official year beginning in December, 1930. Such information is purely of historical nature and is included here as a permanent record. Further information was published in the Membership List for 1931.

Officers and Council

Dates in parentheses denote expiration of terms

PRESIDENT

ROY V. WRIGHT

PAST-PRESIDENTS

Terms expire in December

WILLIAM F. DURAND (1931) — CHARLES M. SCHWAB (1933)
WILLIAM L. ABBOTT (1932) — ALEX DOW (1934)
CHARLES PIEZ (1935)

VICE-PRESIDENTS

Terms expire December, 1931	*Terms expire December, 1932*
PAUL DOTY	HARVEY N. DAVIS
RALPH E. FLANDERS	WILLIAM A. HANLEY
ERNEST L. JAHNCKE	THOMAS R. WEYMOUTH
CONRAD N. LAUER	

MANAGERS

Terms expire December, 1931	*Terms expire December, 1932*
CHARLES M. ALLEN	HAROLD V. COES
ROBERT M. GATES	JAMES D. CUNNINGHAM
ELY C. HUTCHINSON	CLARENCE F. HIRSHFELD

Terms expire December, 1933

WILLIAM L. BATT — HAROLD L. DOOLITTLE — HERBERT L. WHITTEMORE

TREASURER	SECRETARY
ERIK OBERG	CALVIN W. RICE

EXECUTIVE COMMITTEE OF COUNCIL

ROY V. WRIGHT, *Chairman* — HARVEY N. DAVIS
CONRAD N. LAUER, *Vice-Chairman* — ROBERT M. GATES
CALVIN W. RICE, *Secretary* — WILLIAM L. BATT

Advisory Members: Chairmen of the Finance Committee, the Local Sections Committee, and the Professional Divisions Committee.

CHAIRMEN OF STANDING COMMITTEES

Representatives on Council but without vote

Finance, F. A. SCHAFF, *Chairman*
DAVID LOFTS, *Vice-Chairman*
Meetings and Program, G. M. EATON
Publications, F. V. LARKIN
Membership, F. A. WALDRON
Professional Divisions, H. W. BROOKS
Local Sections, H. R. WESTCOTT
Constitution and By-Laws, A. D. BLAKE
Awards, H. L. SEWARD
Relations with Colleges, M. C. MAXWELL
Education and Training for Industries, R. L. SACKETT
Library, A. S. MILLER
Standardization, L. K. SILLCOX
Research, WM. REUBEN WEBSTER
Power Test Codes, F. R. LOW
Safety, H. W. MOWERY
Professional Conduct, JOHN HUNTER

EXECUTIVE SECRETARY	EDITOR
C. E. DAVIES	GEORGE A. STETSON

ASSISTANT SECRETARIES

ERNEST HARTFORD
C. B. LEPAGE

Standing Committees

Dates in parentheses denote expiration of terms

FINANCE

F. A. SCHAFF, *Chairman and Representative on Council* (1931)
DAVID LOFTS, *Vice-Chairman* (1932) — JOHN H. LAWRENCE (1934)
KINGSLEY L. MARTIN (1933) — E. A. MULLER (1935)

Council Representatives:
H. V. COES (1931)
ELY C. HUTCHINSON (1932)

MEETINGS AND PROGRAM

G. M. EATON, *Chairman and Representative on Council* (1931)
F. M. FEIKER (1932) — C. P. BLISS (1934)
J. W. PARKER (1933) — R. I. REES (1935)

PUBLICATIONS

F. V. LARKIN, *Chairman and Representative on Council* (1931)
W. H. WINTERROWD (1932) — S. F. VOORHEES (1934)
L. C. MORROW (1933) — S. W. DUDLEY (1935)

(*Personnel of Special Committee, p. 11*)

MEMBERSHIP

F. A. WALDRON, *Chairman and Representative on Council* (1931)
H. W. BUTLER (1932) — OTTO E. GOLDSCHMIDT (1934)
HOSEA WEBSTER (1933) — HENRY A. LARDNER (1935)

PROFESSIONAL DIVISIONS

H. W. BROOKS, *Chairman and Representative on Council* (1931)
W. F. DIXON (1932) — C. B. PECK (1934)
P. T. SOWDEN (1933) — W. A. SHOUDY (1935)

(*Chairmen of Professional Divisions' Executive Committees, p. 11*)

LOCAL SECTIONS

HARRY R. WESTCOTT, *Chairman and Representative on Council* (1931)
CHARLES W. BENNETT (1932) — JILES W. HANEY (1934)
JAMES M. TODD (1933) — WM. LYLE DUDLEY (1935)

(*Chairmen of Local Sections' Executive Committees, p. 11*)

CONSTITUTION AND BY-LAWS

A. D. BLAKE, *Chairman and Representative on Council* (1931)
THOS. C. MCBRIDE (1932) — H. H. SNELLING (1934)
R. S. NEAL (1933) — P. R. FAYMONVILLE (1935)

AWARDS

H. L. SEWARD, *Chairman and Representative on Council* (1931)
A. M. GREENE, JR. (1932) — F. L. EIDMANN (1934)
K. H. CONDIT (1933) — W. L. BATT (1935)

RELATIONS WITH COLLEGES

M. C. MAXWELL, *Chairman and Representative on Council* (1931)
D. B. PRENTICE (1932) — W. L. ABBOTT (1934)
E. F. CHURCH, JR. (1933) — LEWIS F. GORDON (1935)

(*Student Branches and Honorary Chairmen, p. 11*)

EDUCATION AND TRAINING FOR THE INDUSTRIES

R. L. SACKETT, *Chairman and Representative on Council* (1934)
D. C. JACKSON (1931) — H. S. FALK (1933)
JOHN T. FAIG (1932) — C. F. BAILEY (1935)

LIBRARY

ALTEN S. MILLER, *Chairman and Representative on Council* (1931)
GEORGE F. BATEMAN (1932) — E. P. WORDEN (1934)
W. M. KEENAN (1933) — THE SECRETARY, CALVIN W. RICE

RESEARCH

Organized 1909, to supervise all research activities, collaborating with committees of kindred societies, and obtaining results of researches conducted in the U. S. and other countries

W. Reuben Webster, *Chairman and Representative on Council* (1931)

W. H. Fulweiler (1932)
Alex. D. Bailey (1933)
Andrey A. Potter (1934)
F. C. Biggert, Jr. (1935)

STANDARDIZATION

Organized April, 1911, to supervise all standardization activities of the Society. Cooperates with American Standards Association

L. K. Sillcox, *Chairman and Representative on Council* (1932)

H. B. Taylor (1931)
W. S. Monroe (1933)
E. Buckingham (1934)
B. H. Blood (1935)

POWER TEST CODES

Organized December, 1918, to revise and extend the Power Test Codes of the Society. The Codes had been formulated by various committees appointed from 1886 to that date

Fred R. Low, *Chairman and Representative on Council* (1935)

Term Expires 1931

A. G. Christie
P. Diserens
C. E. Lucke
G. A. Orrok
W. M. White

Term Expires 1932

H. Cooke
E. R. Fish
O. P. Hood
H. B. Oatley
W. J. Wohlenberg

Term Expires 1933

E. H. Brown
I. E. Moultrop
G. A. Horne
L. S. Marks
E. N. Trump

Term Expires 1934

C. H. Berry
F. Hodgkinson
D. S. Jacobus
L. F. Moody
E. B. Ricketts

Term Expires 1935

F. R. Low
A. T. Brown
R. H. Fernald
C. F. Hirshfeld
R. J. S. Pigott

SAFETY

Appointed October, 1921, to extend knowledge of safety, to promote cooperation in this field and to supervise all safety code activities of Society with exception of those of Boiler Code group of committees

H. W. Mowery, *Chairman and Representative on Council* (1933)

L. R. Palmer (1931)
L. Price (1932)
T. A. Walsh, Jr. (1934)
M. H. Christopherson (1935)

PROFESSIONAL CONDUCT

John Hunter, *Chairman and Representative on Council* (1931)

William B. Powell (1932)
A. G. Christie (1933)
H. S. Philbrick (1934)
D. Robert Yarnall (1935)

A.S.M.E. Representatives on Joint Activities

Dates in parentheses denote expiration of term

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION M, ENGINEERING

R. L. Daugherty — Wm. B. Gregory

Representatives or alternates appointed according to geographical location of meetings

AMERICAN ENGINEERING COUNCIL

Terms expire January 1, 1932

L. P. Alford, New York, N.Y.
Thomas D. Campbell, Hardin, Mont.
William B. Ferguson, Newport News, Va.
Charles E. Ferris, Knoxville, Tenn.
John Lyle Harrington, Kansas City, Mo.
William H. Kenerson, Providence, R.I.
John H. Lawrence, New York, N.Y.
Richard C. Marshall, Jr., Chicago, Ill.
A. A. Potter, Lafayette, Ind.
Max Toltz, St. Paul, Minn.

Terms expire January 1, 1933

Roy V. Wright, *Chairman*, New York, N.Y.
W. S. Conant, New York, N.Y.
E. O. Eastwood, Seattle, Wash.
B. E. Hull, Houston, Tex.
Jos. W. Roe, New York, N.Y.
Warner Seely, Cleveland, Ohio.
W. Trinks, Pittsburgh, Pa.
E. N. Trump, Syracuse, N.Y.
W. R. Webster, New York, N.Y.
D. Robert Yarnall, Philadelphia, Pa.

AMERICAN SOCIETY OF SAFETY ENGINEERS

ENGINEERING SECTION, NATIONAL SAFETY COUNCIL

H. W. Mowery — Ernest Hartford

AMERICAN STANDARDS ASSOCIATION

C. P. Bliss (1931)[4] — Cloyd M. Chapman (1933)
Lewis K. Sillcox — K. H. Condit (*alternate*)
C. B. Le Page (*alternate*)

EDUCATIONAL RESEARCH COMMITTEE

THE ENGINEERING FOUNDATION

Harvey N. Davis

THE ENGINEERING FOUNDATION

H. Hobart Porter (1932)[5] — A. E. White (1933)
D. Robert Yarnall (1934)

GANTT MEDAL BOARD OF AWARD

W. L. Conrad — Conrad N. Lauer
Dexter S. Kimball

GUGGENHEIM MEDAL BOARD OF AWARD

H. I. Cone (1931) — E. E. Aldrin (1933)
W. F. Durand (1932) — George W. Lewis (1934)

HERBERT HOOVER MEDAL BOARD OF AWARD

Ambrose Swasey — Dexter S. Kimball
Calvin W. Rice

INSTITUTE OF HUMAN RELATIONS

ADVISORY COMMITTEE

H. M. Crane — H. E. Howe
Ralph E. Flanders — J. P. Jordon
E. W. Rice, Jr. — Calvin W. Rice, *Ex-Officio*

INTERNATIONAL ELECTROTECHNICAL COMMISSION

U. S. NATIONAL COMMITTEE

C. H. Berry — F. Hodgkinson
H. N. Davis — E. C. Hutchinson
P. Diserens — F. R. Low
W. F. Durand — I. E. Moultrop

[4] Represents the A.S.M.E. on the Executive Committee of the A.S.A.
[5] A.S.M.E. representatives from Board of United Engineering Trustees.

INTERNATIONAL MANAGEMENT CONGRESS COMMITTEE OF THE U. S. A.

L. P. Alford — Calvin W. Rice

JOHN FRITZ MEDAL BOARD OF AWARD

The terms of office expire in October of each year

Charles M. Schwab (1931) — W. L. Abbott (1933)
Alex Dow (1932) — Charles Piez (1934)

JOSEPH A. HOLMES SAFETY ASSOCIATION

O. P. Hood

LIBRARY BOARD

MONOGRAPHS ADVISORY COMMITTEE

W. A. Shoudy — S. W. Dudley

NATIONAL RESEARCH COUNCIL

DIVISION OF ENGINEERING

R. J. S. Pigott (June, 1931) — A. E. White (June, 1932)
R. L. Streeter (June, 1933)

ALFRED NOBLE PRIZE

L. P. Alford

THE PRESIDENT'S EMERGENCY COMMITTEE ON EMPLOYMENT

A.S.M.E. COOPERATING COMMITTEE

Ralph E. Flanders, *Chairman* — Ely C. Hutchinson
Dexter S. Kimball — C. H. Crawford
J. W. Roe — W. A. Starrett
Ex-Officio: Roy V. Wright, President, A.S.M.E.
Calvin W. Rice, Secretary, A.S.M.E.

REGISTRATION OF ENGINEERS

D. S. Kimball, *Chairman* — C. F. Hirshfeld
Virgil M. Palmer, *Vice-Chairman* — J. M. Todd
Paul Doty — Calvin W. Rice (*alternate*)

SPIRIT OF ST. LOUIS MEDAL BOARD OF AWARD

P. deC. Ball — H. I. Cone
W. F. Durand — J. L. Doolittle
W. B. Mayo — Orville Wright

UNITED ENGINEERING TRUSTEES, INC.

H. Hobart Porter (1932) — H. V. Coes (1933)
Edwards R. Fish (1934)

WESTERN SOCIETY OF ENGINEERS

WASHINGTON AWARD

James D. Cunningham (June, 1931) — Julius L. Hecht (1932)

GENERAL ASSIGNMENTS[6]

American Bureau of Welding, Advisory Board of the National Research Council, James Partington.
American Bureau of Welding, Advisory Committee on Structural Steel Welding, Geo. A. Orrok.
American Bureau of Welding, Gas Welding Committee, James Partington and C. W. Obert.
International High Commission, Advisory Committee to the U. S. Section, concerned with a preliminary study and compilation of a report on the use of Uniform Weights and Measures, Ralph E. Flanders.
National Screw Thread Commission, Luther D. Burlingame.
Standardization Survey Committee, C. M. Schwab, H. Birchard Taylor (alternate).
U. S. Department of Commerce, National Committee on Metals Utilization, Stanley G. Flagg, Jr.
U. S. Department of Commerce, National Conference on Street and Highway Safety, E. J. Posselt.
U. S. Shipping Board, Fuel Conservation Board, H. L. Seward.

[6] The Society is also represented on a number of technical committees sponsored by other organizations.

Exchange of Courtesies

Special arrangements have been made between the A.S.M.E. and the following organizations whereby their members will be mutually accorded such courtesies as the use of reading and writing rooms, assistance in securing general information and in arranging to visit industrial plants, receipt of mail, etc.

Austria	
Vienna	Osterreichischer Ingenieur und Architekten Verein
Belgium	
Bruxelles	Federation des Associations Belges d'Ingenieurs
	Société Belge des Ingenieurs et des Industriels
Canada	
Montreal	The Engineering Institute of Canada
Cuba	
Havana	Sociedad Cubana de Ingenieros
Czechoslovakia	
Prague	Association of Czechoslovakian Engineers and Architects in Praha

Awards

The Committee on Awards, given on page 9, has supervision of the awards of the Society under the direction of the Council. Awards and special funds are administered as specified in the deeds of gift or as may be determined by the Council from time to time. The following awards come within the jurisdiction of the Society. A list of the recipients of awards previous to 1931 will be found in the 1930 Record and Index, pages 18–20.

Honorary Membership, to which persons of acknowledged professional eminence are elected by unanimous vote of Council under the provisions of the By-Laws and Rules. A list of honorary members is given on page 15.

Life Membership, which may be conferred by the Council for distinguished service to the Society.

A.S.M.E. Medal, established by the Society in 1920 to be presented for distinguished service in engineering and science. May be awarded for general service in science having possible application in engineering. Award for 1931 to Albert Kingsbury for his research and development work in the field of lubrication.

Holley Medal, instituted and endowed in 1924 by George I. Rockwood, Past Vice-President of the Society, to be bestowed for some great and unique act of genius of engineering nature that has accomplished a great and timely public benefit.

Melville Medal, established in 1914 by the bequest of Rear-Admiral George W. Melville, Honorary Member and Past-President of the Society, to be presented for an original paper or thesis of exceptional merit, presented to the Society for discussion and publication, to encourage excellence in papers. May be presented annually. Award for 1931 to A. E. Grunert for his paper entitled "Comparative Performance of a Pulverized-Coal-Fired Boiler Using Bin System and Unit System of Firing."

Spirit of Saint Louis Medal, endowed by members of the Society and citizens residing in St. Louis, Mo., to be awarded for meritorious service in the field of aeronautical engineering. This medal will be awarded at the discretion of the Council of the Society at approximately three-year periods upon the recommendation of a Spirit of Saint Louis Medal Board of Award made up of six members, each appointed for a term of nine years and the terms of two members expiring at each three-year period. The St. Louis Section and the Aeronautic Division will each nominate three members. The first medal was awarded to Daniel Guggenheim in 1929.

Worcester Reed Warner Medal, provision for which was made in the will of Worcester Reed Warner, Honorary Member of the Society, is to be a gold medal to be bestowed on the author of the most worthy paper received, dealing with progressive ideas in mechanical engineering or efficiency in management.

Junior Award, annual cash award of $50, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with an engraved certificate, for the best paper or thesis submitted by a Junior Member. Award for 1931 to M. K. Drewry for his paper entitled "Radiant-Superheater Developments."

Student Awards, two annual cash awards of $25 each, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with engraved certificates, for the best papers or theses submitted by Student Branch Members. One award for 1931 to Jules Podnossoff of the Polytechnic Institute of Brooklyn for his paper entitled "Pressure and Energy Distribution in Multi-Stage Steam Turbines Operating Under Varying Conditions."

Charles T. Main Award, annual cash award of $150, established in 1919 from a fund created by Charles T. Main, Past-President of the Society, to be awarded to a student of engineering, preferably a member of a Student Branch of the Society, for the best paper within the general subject of the "Influence of the Profession upon Public Life." The exact subject is assigned by the Committee on Awards, subject to the approval of the Council, and is announced each year through the Honorary Chairmen of the Student Branches. Award for 1931 to Robert E. Klise of the University of Michigan for his paper on "Interchangeability—Its Development and Significance in Industry."

SCHOLARSHIPS AND LOAN FUNDS

Max Toltz: Loan Fund of $15,000 established by Major Max Toltz, former member of the Council of the Society, the income to be used for assistance to students.

John R. Freeman: Fund of $25,000 established in 1926 by John R. Freeman, Past-President of the Society, the income to be used for travel scholarships and research. Scholarships have been awarded as follows: Herbert N. Eaton and Blake R. Van Leer, 1927; Robert T. Knapp, 1929; and Reginald Whitaker, 1931.

Woman's Auxiliary: Scholarship or Fellowship offered by the Woman's Auxiliary to the Society to assist sons and daughters of members or worthy students of mechanical engineering.

JOINT AWARDS

The A.S.M.E. participates in three joint awards, the Herbert Hoover Medal, the John Fritz Medal, and the Washington Award.

The Herbert Hoover Medal

The Hoover Gold Medal was instituted in 1930 to commemorate the civic and humanitarian achievements of Herbert Hoover and the first award was made to Herbert Hoover on April 8, 1930. From time to time the medal will be awarded by engineers to a fellow engineer for distinguished public service.

The trust fund creating the award was the gift of Conrad N. Lauer, of Philadelphia. The American Society of Mechanical Engineers is the custodian of the fund, which is administered by a Board of Award composed of representatives appointed by the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers.

The John Fritz Medal

The John Fritz Medal was established in August, 1902, by the professional associates and friends of the late John Fritz, Past-President and Honorary Member of the A.S.M.E., to perpetuate the memory of his achievement in industrial progress.

The medal is awarded not more than once each year for notable scientific or industrial achievement, with no restrictions on account of sex or nationality. The award is made by a Board of sixteen, four representatives from each of the four national engineering societies, the A.S.C.E., A.I.M.E., A.S.M.E., and A.I.E.E.

The Washington Award

The Washington Award was founded in 1916 by John Watson Alvord, to be awarded annually by the Western Society of Engineers upon the recommendation of a Commission composed of nine representatives of that society and two representatives of each of the four national engineering societies, the A.S.C.E., A.I.M.E., A.S.M.E., and A.I.E.E. It is bestowed in recognition of devoted, unselfish, and preeminent service in advancing human progress through engineering.

The award for 1931 was made to Ralph Modjeski for his contribution to transportation through superior skill and courage in bridge design and construction.

Honorary Members

HONORARY MEMBERS IN PERPETUITY

Alexander Lyman Holley, Founder of the Society. Died 1882.

John Edson Sweet, Founder of the Society. Died 1916.

Henry Rossiter Worthington, Founder of the Society. Died 1880.

DECEASED HONORARY MEMBERS

	ELECTED	DIED
Horatio Allen	1880	1889
Sir William Arrol	1905	1913
Sir Benjamin Baker	1886	1907
Johann Bauschinger	1884	1893
Sir Henry Bessemer	1891	1898
Sir Frederick Joseph Bramwell	1884	1903
John Alfred Brashear	1908	1920
Gustave Canet	1900	1908
Andrew Carnegie	1907	1919
Daniel Kinnear Clark	1882	1896
Rudolph Julius Emmanuel Clausius	1882	1888
Sir John Coode	1889	1892
Peter Cooper	1882	1883
Carl Gustaf Patrik de Laval	1912	1913
Rudolph Diesel	1912	1913
James Dredge	1886	1906
Victor Dwelshauvers-Dery	1886	1913
Thomas Alva Edison	1904	1931
Alexandre Gustave Eiffel	1889	1923
Marshal Ferdinand Foch	1921	1929
Sir Charles Douglas Fox	1900	1921
John Fritz	1900	1913
Major - General George Washington Goethals	1917	1928
Franz Grashof	1884	1893
Otto Hallauer	1882	1883
Charles Haynes Haswell	1905	1907
Friedrich Gustav Herrmann	1884	1907
Gustav Adolph Hirn	1882	1890
Joseph Hirsch	1889	1901
Ira N. Hollis	1928	1930
Robert Woolston Hunt	1920	1923
Benjamin Franklin Isherwood	1894	1915
Henri Léauté	1891	1916
Erasmus Darwin Leavitt	1915	1916
Anatole Mallet	1912	1919
Charles H. Manning	1913	1919
Rear-Admiral George Wallace Melville	1910	1912
The Honorable Sir Charles Algernon Parsons	1920	1931
Charles Talbot Porter	1890	1910
Auguste C. E. Rateau	1919	1930
Sir Edward J. Reed	1882	1906
Franz Reuleaux	1882	1905
Henri Adolphe - Eugene Schneider	1882	1898
C. William Siemans	1882	1883
Viscount Ei-ichi Shibusawa	1929	1931
Henry Robinson Towne	1921	1924
Henri Tresca	1882	1885
Francis A. Walker	1886	1897
Worcester Reed Warner	1925	1929
Sir William Henry White	1900	1913
George Westinghouse	1897	1914

LIVING HONORARY MEMBERS

	ELECTED
Sir John Audley Frederick Aspinall	1911
William Wallace Atterbury	1925
Mortimer Elwyn Cooley	1928
Charles de Fréminville	1919
Rear-Admiral Robert Stanislaus Griffin	1920
Nathanael Greene Herreshoff	1921
Honorable Herbert Clark Hoover	1925
Masawo Kamo	1929
Henri Le Chatelier	1927
Grande Ufficiale Ing. Pio Perrone	1920
Calvin Winslow Rice	1931
Palmer C. Ricketts	1931
Charles M. Schwab	1918
Ambrose Swasey	1916
Elihu Thomson	1930
William Cawthorne Unwin	1898
Samuel Matthews Vauclain	1920
Oskar von Miller	1912
Right Honorable Lord Weir	1920
Orville Wright	1918
Sir Alfred Fernandez Yarrow	1914

Past Officers[7]

ALEXANDER LYMAN HOLLEY, Chairman of the Preliminary Meeting for Organization of The American Society of Mechanical Engineers.
Died January 29, 1882

PRESIDENTS

ROBERT HENRY THURSTON Died October 25, 1903	1880–1882
ERASMUS DARWIN LEAVITT Died March 11, 1916	1883
JOHN EDSON SWEET Died May 8, 1916	1884
JOSEPHUS FLAVIUS HOLLOWAY Died September 1, 1896	1885
COLEMAN SELLERS Died December 28, 1907	1886
GEORGE H. BABCOCK Died December 16, 1893	1887
HORACE SEE Died December 14, 1909	1888
HENRY ROBINSON TOWNE Died October 15, 1924	1889
OBERLIN SMITH Died July 19, 1926	1890
ROBERT WOOLSTON HUNT Died July 11, 1923	1891
CHARLES HARDING LORING Died February 5, 1907	1892
ECKLEY BRIXTON COXE Died May 13, 1895	1893–1894
EDWARD F. C. DAVIS Died August 6, 1895	1895
CHARLES ETHAN BILLINGS Died June 4, 1920	1895
JOHN FRITZ Died February 13, 1913	1896
WORCESTER REED WARNER Died June 25, 1929	1897
CHARLES WALLACE HUNT Died March 27, 1911	1898
GEORGE WALLACE MELVILLE Died March 17, 1912	1899
CHARLES HILL MORGAN Died January 10, 1911	1900
SAMUEL T. WELLMAN Died July 11, 1919	1901
EDWIN REYNOLDS Died February 19, 1909	1902
JAMES MAPES DODGE Died December 4, 1915	1903
AMBROSE SWASEY Cleveland, Ohio	1904
JOHN RIPLEY FREEMAN Providence, R. I.	1905
FREDERICK WINSLOW TAYLOR Died March 21, 1915	1906
FREDERICK REMSEN HUTTON Died May 14, 1918	1907
MINARD LAFEVER HOLMAN Died January 4, 1925	1908
JESSE MERRICK SMITH Died April 1, 1927	1909
GEORGE WESTINGHOUSE Died March 12, 1914	1910 1911
EDWARD DANIEL MEIER Died December 15, 1914	
ALEXANDER CROMBIE HUMPHREYS Died August 14, 1927	1912
WILLIAM FREEMAN MYRICK GOSS Died March 23, 1928	1913
JAMES HARTNESS Springfield, Vt.	1914
JOHN ALFRED BRASHEAR Died April 8, 1920	1915
DAVID SCHENCK JACOBUS New York, N. Y.	1916
IRA NELSON HOLLIS Died August 15, 1930	1917
CHARLES THOMAS MAIN Boston, Mass.	1918
MORTIMER ELWYN COOLEY Ann Arbor, Mich.	1919
FRED J. MILLER Center Bridge, Pa.	1920
EDWIN S. CARMAN Cleveland, Ohio	1921
DEXTER SIMPSON KIMBALL Ithaca, N. Y.	1922
JOHN LYLE HARRINGTON Kansas City, Mo.	1923
FREDERICK ROLLINS LOW New York, N. Y.	1924
WILLIAM FREDERICK DURAND Stanford Univ., Calif.	1925
WILLIAM LAMONT ABBOTT Chicago, Ill.	1926
CHARLES M. SCHWAB New York, N. Y.	1927
ALEX DOW Detroit, Mich.	1928
ELMER AMBROSE SPERRY Died June 16, 1930	1929
CHARLES PIEZ Chicago, Ill.	1930
ROY V. WRIGHT New York, N. Y.	1931

NOTE: According to the Constitution, Article C7, Sec. 2, the last five surviving Past-Presidents are members of the Council.

[7] A list of past vice-presidents, managers, treasurers, and secretaries will be found in the 1930 Record and Index, pages 10–12.

Report of Council

THE Society made significant progress during the year 1930–1931 as a result of the cumulative efforts of many individuals and active groups organized in committees. This progress, which covered a wide range of professional engineering achievement, was carried on during a period of industrial and economic stress which made the work of the individual members of the Society much more difficult and the results of it therefore much more praiseworthy.

A noteworthy feature of the year's development was the untiring and enthusiastic attitude of the President of the Society, Dr. Roy V. Wright, who during his term of office visited every one of the 71 Sections and 66 of the 108 Student Branches. Dr. Wright aroused the members of the Society to the need for more thorough understanding by them of the economic and social implications of the work of the engineer. The net result was the quickening of interest in the problem which will undoubtedly result in broadening and deepening the professional life of the Society. Dr. Wright is entitled to the sincere gratitude of every member.

Another notable factor was the opportunity provided for members to participate in Society activities. Four meetings of the Society outside of New York City, 17 national meetings of Professional Divisions, 471 meetings of Local Sections, and 143 technical committee meetings mark a high point in the number of gatherings. This policy of providing more opportunities for members throughout the nation to take part in Society work is a logic corollary of President Wright's recent campaign to arouse interest in that work.

A unique achievement of the technical committees was the survey of screw-thread practice in the United States, sponsored by the S.A.E. and the A.S.M.E. with the National Bureau of Standards cooperating. Over 163 firms manufacturing and using threaded products were visited by the Committee's representative and approximately 7600 bolts, nuts, and screws were collected and shipped to the National Bureau of Standards for measurement in an effort to judge the extent to which the American National Standard Screw Thread has measured up to commercial requirements and in what respect revisions should now be made.

An important program for future progress has grown out of the Report of the Committee on the Economic Status of the Engineer, a fact-finding study which appeared in the September issue of *Mechanical Engineering* and which has provided the basis for developing the professional position of the engineer.

The problem of affiliating the student members more closely with the work of the Society was brought nearer to a satisfactory solution during the year. An auspicious beginning was made at the French Lick Meeting shortly after the opening of the fiscal year where an unusually successful student session was held. The year closed with the initiation of a program for the organization of Student Branches as fundamental units of the Society. The plan that has been decided upon offers great promise for the future development of the engineering profession.

The Pure Air Committee, organized to focus the influence of the engineering profession on reducing smoke, dust, and fumes, was a logical and important addition to the list of similar committees that are devoted to the public interest.

The accompanying table shows the changes in membership during the year, resulting in a total of 20,040 as of November, 1931. The Society mourns the loss from the distinguished group of Honorary Members of Thomas Alva Edison, Member of the Society since 1880, Honorary Member since 1904; the Honorable Sir Charles Algernon Parsons; and Viscount Ei-ichi Shibusawa.

Meetings of the Council were held during the Annual Meeting in December, 1930, at the Semi-Annual Meeting, Birmingham, in April, 1931, the Hartford Meeting in June, and by special representation at the Kansas City Meeting in September. The Executive Committee of the Council has met more frequently and has attended to urgent and detailed Council business.

Presidential appointments and special representations, outside of the regular routine appointments for the year, have totaled more than 100, including those for the Seventy-Fifth Anniversary of the Verein deutscher Ingenieure, attended by a group of about 70 from this country, the Faraday Centenary in London, and several century and half-century anniversaries of foreign and American Colleges and societies, as well as International Congresses and similar celebrations.

A gift has come to the Society from the bequest of C. B. F. Waller of Philadelphia, Member of the Society.

Coordinating the public and joint activities of its 26 engineering member societies, the American Engineering Council has done some notable work in the programs for the relief of unemployment, both through the President's Committee and the A.E.C. plan to be carried out throughout the United States by engineering societies and their local sections. A report on technological unemployment submitted to the Department of Labor by a special committee of the societies through the A.E.C. has been favorably received. Bulletins of the A.E.C. record its most important work, in which the Society participates.

The reports that follow are worthy of careful study.

CALVIN W. RICE, *Secretary*.

MEMBERSHIP CHANGES—OCTOBER 1, 1930, TO SEPTEMBER 30, 1931

FINANCE

The year 1930–1931 brought a number of problems in the financing of the Society. The reduction in income from advertising necessitated reductions in expenditures as compared to the previous year; but without serious curtailment of Society activities. By the provision of the By-Laws, the income from initiation fees is not included in the estimate of income when the budget of expenditures is prepared and is placed in a special reserve. The expenditures ex-

ceeded the other income of the Society by $9896.58, which the Council authorized to be taken from accumulated surplus reserve.

While the earning power of our invested securities has not declined, the market value has declined somewhat, making it prudent to ear-mark a portion of our reserves as Reserve against Depreciation of Securities; $15,000 has been set aside for this purpose, merely in the event of an emergency that might require the sale of some securities in a depreciated market.

The Society has built up a reputation for paying bills and has found it to advantage, toward the end of the year, to borrow for short periods rather than to sell investments. This financing is necessary as the Mechanical Catalog billings are not made until September 30, the last day of the fiscal year, while expenditures against that income are incurred throughout the year. The amount borrowed this year was $170,000, an increase of $50,000 over the previous year, necessary to pay bills outstanding at the close of the fiscal period and because of an increase in needs for cash to operate The Engineering Index.

The Engineering Index passed through its fourth year and made an excellent showing in the face of the present situation. The income was $108,508.64, the expenses $113,379.71, showing an operating deficit of $4871.07. Means have been found for producing the Index more economically, and it is expected that during the coming fiscal year the Index will begin to repay the advances that have been made for its development.

Total Income

The following table gives a comparison of the total income of the Society for the fiscal year ending September 30, 1930:

	1929–1930	1930–1931
Initiation Fees	$ 30,430.17	$ 25,863.27
Membership Dues	314,815.87	314,828.31
Advertising and Publication Sales (less bad debts)	439,704.08	377,132.72
Interest and Discount	23,601.18	22.080.10
Miscellaneous Sales	5,529.10	3,364.35
	$814,080.40	$743,268.75

The 1929–1930 fiscal year was exceptional because of the large income from the special Fiftieth Anniversary issue of *Mechanical Engineering*.

Expenditures

During the 1930–1931 year a simplified scheme of accounting was installed, which provided that for control purposes the expenditures of the Society should be segregated into three major classes: Committee Expenses, Printing and Distributing Publications, and Expenses of the Administrative Office.

Committee Expenses are those which are incurred by direct action of the committees or Council. The Administrative Office Expenses are those incurred in the office of the Secretary to carry out the work of the various committees and to execute policies approved by the Council. The expenditures according to this classification are as follows:

	1929–1930	1930–1931
Committee Expenses	$114,380.01	$116,073.62
Reserve for Engineering Index Development	5,000.00	.....
Publications (Printing and Distribution only)	242,847.38	230,932.77
Administrative Office	412,804.34	380,295.57
	$775,031.73	$727,301.96
To Reserve	39,048.67	15,966.79
	$814,080.40	$743,268.75

The use to which these expenditures are put in carrying on the work of the Society is shown in the following tabulation:

	1929–1930	1930–1931
General	$ 41,754.43	$ 44,630.18
Society Activities	171,470.63	175,241.50
Technical Committees	66,475.18	64,883.97
Text Publications (Printing, Editorial, and Distribution)	188,232.12	179,390.56
Advertising and Sales (Printing, Soliciting, and Distribution)	302,099.37	263,155.75
Reserve for Engineering Index Development	5,000.00	.....
	$775,031.73	$727,301.96

General Expenses include those for Council, the Library, American Engineering Council, the study of the Committee on the Economic Status of the Engineer, Awards, and miscellaneous. The increase of nearly $3000 was used by the Council (including the traveling expenses of the President) and in the study of the Earnings of Mechanical Engineers under the auspices of the Committee on the Economic Status of the Engineer.

Expenses for Society Activities include those for Meetings, Local Sections, Professional Divisions, Student Branches, Employment Service, and for the staff to support these activities and to carry on the routine of securing and handling membership applications for the Membership Committee. The increase of $3800 was due to an increase of $1000 in direct expenditure by the Professional Divisions and to an increase in staff support to Sections and Divisions in the Mid-Continent area.

Technical Committee expenses include the direct expenses to the International Electrotechnical Commission ($1320), American Standards Association ($1500), grants in aid of research ($1286.55), and staff expenses to support the Boiler Code, Research, Standardization, Power Test Codes, and Safety Committees. The decrease from the previous year is in grants for research and in the staff.

Text publications includes the expenses for printing, distributing, and editing Transactions, the *A.S.M.E. News*, Membership List, and the text pages of *Mechanical Engineering*. In 1929–1930 the

Note: The average membership during 1930–1931 was 19,878. The income from membership dues is made up of income from about 14,300 members at $20 each and from 4400 Juniors at $10 each. First year Juniors who pay partial dues, honorary members, life members, etc., make up the remainder of the membership

April issue of *Mechanical Engineering*, devoted to the Fiftieth Anniversary, entailed unusual expenses, which were provided by increased advertising income. The decrease in 1930–1931 is due to the absence of these special expenditures and to fewer pages in Transactions.

Expenses of Advertising and Sales include (1) printing and distributing the Mechanical Catalog and the advertising pages of *Mechanical Engineering*, (2) cost of securing advertising income, (3) printing and distributing publications sold, and (4) the expenses of the publication sales department. The decrease in this item is due to the reduced number of advertising pages sold and printed.

Income and Expenses per Member

The chart above shows the income and expenses for 1930–1931 reduced to a per member basis.

Balance Sheet

The accompanying comparative balance sheet explains the status of our liabilities and assets and shows the changes that have taken place during the fiscal year.

F. A. Schaff, *Chairman* J. H. Lawrence

A.S.M.E. COMPARATIVE BALANCE SHEET

ASSETS

	September 30, 1930		September 30, 1931	
CURRENT ASSETS				
Cash in Bank and on Hand	$ 6,965.99		$ 12,674.63	
Accounts Receivable	166,150.97		186,905.04	
(Money due the Society from members for dues, from advertisers in Mechanical Catalog and Mechanical Engineering, from sale of Engineering Index Service and from sale of Publications. Increase of $20,754.07 due to inclusion of Engineering Index item.)				
Inventories	114,873.36		140,239.56	
(Supplies at cost, publications in process of manufacture and completed publications in the stock room for sale. Increase of $25,366.20 due to drop in expected sale of index and large orders completed just before close of the fiscal period.)				
TOTAL CURRENT ASSETS		287,990.32		339,819.23
INVESTMENTS				
Trust Funds	164,035.45		166,764.94	
(Funds entrusted to the Society for specific purposes. Net increase of $2,729.49 due to accrued interest and addition of Waller Fund less expenditures of $2000 for Hoover Medal.)				
Invested Reserve	343,381.25		343,381.25	
(Securities purchased from proceeds of initiation fees and excess of income over expenditures in previous years.)				
Advances				
Physical Properties of Steam	15,000.00		15,000.00	
(A loan at interest to the Special Research Committee in Charge.)				
Engineering Index Service	110,981.45		112,916.80	
(A loan at interest for the establishment of the Engineering Index Service. Increase of $1,935.35 due to operating loss of $4,871.07 less depreciation paid of $2,935.72.)				
TOTAL INVESTMENTS		633,398.15		638,062.99
FIXED ASSETS				
United Engineering Trustees, Inc.	493,352.60		496,948.48	
(One-quarter interest in building. Depreciation is carried on the books of U.E.T., Inc. Increase of $3,585.88 on basis of changed value ordered by U.E.T., Inc.)				
Furniture and Equipment	22,327.74		24,094.93	
Library Books	1.00		1.00	
Engineering Index	1.00		1.00	
TOTAL FIXED ASSETS		515,682.34		521,045.41
DEFERRED CHARGES				
50th Anniversary	29,399.66		24,399.66	
(Advanced in 1930, being repaid at rate of $5000 per year.)				
Society Activities	15,820.03		3,001.41	
(Money paid in advance for activities provided in budget of next fiscal year.)				
TOTAL DEFERRED CHARGES		45,219.69		27,401.07
TOTAL ASSETS		$1,482,290.50		$1,526,328.73

LIABILITIES

	September 30, 1930		September 30, 1931	
CURRENT LIABILITIES				
Accounts Payable	$ 20,405.85		$ 0.00	
(Amounts billed to Society and due. Reduction of $20,405.85 possible by larger borrowing.)				
Unfilled Commitments	43,937.28		32,391.15	
(Commitments for printing and distributing Mechanical Catalog. Bills not due but income from Catalog is credited during current fiscal period. Reduction of $11,546.13 due to decreased cost of Catalog.)				
Gleason Gift for Thurston Biography	460.82		460.82	
Notes Payable	120,000.00		170,000.00	
(Borrowing from bank for current financing. Increase of $50,000 needed for accounts payable and for current financing on Engineering Index.)				
TOTAL CURRENT LIABILITIES		184,803.95		202,851.97
CUSTODIAN FUNDS		23,757.09		27,715.93
(Funds in the custody of the Society to be expended for research at the direction of some thirty Committees which collected the funds.)				
DUES PAID IN ADVANCE		4,349.81		3,572.36
TRUST FUNDS		164,035.45		166,764.94
RESERVES				
Staff Retirement Reserve Fund	26,232.32		26,232.32	
Initiation Fee Reserve Fund	169,288.78		195,152.05	
(By-Laws require that initiation fees be placed in reserve fund. Increase of $25,863.27 is amount of initiation fees received in 1930–31.)				
Previous Surplus Invested	147,860.15		106,996.88	
(Reduction of $40,863.27, $25,863.27 of which was to provide additional working capital during 1930–1931 and $15,000 of which was transferred to establish a Reserve against Depreciation of Securities.)				
Engineering Index Development Reserve	25,000.00		25,000.00	
Reserve Fund Against Depreciation of Securities	0.00		15,000.00	
TOTAL RESERVES		368,381.25		368,381.25
CAPITAL				
In Fixed Assets	515,682.34		521,045.41	
Working Capital	221,280.61		235,996.87	
TOTAL CAPITAL		736,962.95		757,042.28
TOTAL LIABILITIES		$1,482,290.50		$1,526,328.73

MEETINGS AND PROGRAM

Five meetings were held during the year under the direct supervision of the Committee on Meetings and Program, as follows: French Lick, Ind., October 13–15, 1930, Annual Meeting in New York, December 1–5, 1930, Semi-Annual Meeting in Birmingham, Ala., April 20–23, 1931, Hartford, Conn., June 1–3, 1931, and Kansas City, Mo., Sept. 7–9, 1931.

French Lick Meeting

Excellent technical sessions and an attractive outdoor program made this meeting an enjoyable occasion. A Student Session proved to be one of the most interesting of the technical events; papers were presented by students representative of six universities on such varied topics as power industry, cooperative education, research in mechanical engineering, machine tools, mechanical engineering in the coal industry, heat treatment of nickel steel welds, and instruction in flying to engineering students. Dr. C. E. Grunsky, President of the American Engineering Council, delivered an inspiring message at a luncheon for the students and Council members, and addresses of interest were also given at the informal dinner and banquet.

Annual Meeting

The Fifty-First Annual Meeting broke all records for attendance—2562, which exceeded the attendance of the previous meeting by almost 400. An event which attracted a large attendance was the general conference on employment which was addressed by Col. Arthur S. Woods, Chairman of the President's Emergency Committee for Employment.

An Exhibition of Art by Engineers, initiated at this meeting, proved so interesting and delightful and aroused such enthusiasm that it was decided to repeat it at the next Annual Meeting. The formal opening of the exhibition was preceded by an hour of music by the "Bridge Engineers' Trio," composed of prominent consulting bridge engineers. More than 200 exhibits were on display, covering sculpture, paintings, prints, line drawings, and photographs by 78 professional engineers.

Another innovation at this meeting was the delivery of three lectures on "Talking With an Audience" by Dr. S. Marion Tucker, Head of the Department of English, The Polytechnic Institute, Brooklyn, which preceded the technical sessions on three mornings and which were so well attended that the Committee has made arrangements to have Dr. Tucker continue these talks at the next meeting.

At the usual New Members' Dinner, the outstanding features were the presentation of special badges to 14 fifty-year members of the Society, the award of the John Fritz Medal to Admiral David Watson Taylor, and the address of the evening given by Elliott Dunlap Smith, director of industrial engineering at Yale University, on the subject "Engineering Encounters Human Nature."

Birmingham Meeting

Southern hospitality and an excellent program of technical papers, well discussed, made the Birmingham meeting a splendid success.

The high spot of the meeting was the dinner at which addresses were given by Roy V. Wright and Dr. Harrison E. Howe. At this meeting also a session with papers contributed entirely by students proved of great interest. A special all-day excursion was arranged to the properties of the Tennessee Coal, Iron, and Railroad Company and a stop for a barbecue luncheon provided a delightful interlude. A second all-day excursion was arranged for the last day of the meeting to the Jordan Dam of the Alabama Power Company, where a modern high-head development was inspected.

Hartford Meeting

Technical papers of high excellence, noteworthy discussions on economic problems, entertainment features of unusual quality, and instructive plant visits marked the Hartford Meeting. A session on stabilization of employment proved one of the leading attractions and provided an opportunity for the exchange of views on many economic subjects. Howell Cheney of Cheney Brothers led this discussion.

A Lamb Bake which the Local Committee arranged was a great success, as was a musicale followed by addresses at the new Horace Bushnell Memorial Auditorium. Among those who spoke were the Honorable Hiram Bingham, Senator from Connecticut, whose subject was "The Engineer in Public Life," and F. M. Ryan of the Bell Telephone Laboratories, who gave an illustrated lecture on "Airplane Telephony." At the informal banquet, President Wright and E. E. Wilson, President of the Chance Vought Corporation and the Sikorsky Aviation Corporation, delivered addresses.

Kansas City Meeting

The participation of a number of organizations, including this Society, in the first Power Conference in the Southwest was an arrangement which offered an excellent opportunity for exchange of ideas on the different phases of power problems. The special program of this Society arranged by the Local Committee contributed in no small way to the success of the meeting.

In addition to these meetings, a session was held at the Annual Meeting of the American Society for Testing Materials, sponsored jointly by that Society and the A.S.M.E. Special Research Committee on Effect of Temperature on the Properties of Metals. The Committee on Meetings and Program was represented at the annual meeting of the Society for the Promotion of Engineering Education at Purdue in June by J. W. Parker, member of the Committee, who gave a talk on "The Need for Speech Training for Engineers."

Respectfully submitted,

G. M. Eaton, *Chairman*
F. M. Feiker
J. W. Parker
C. P. Bliss
R. I. Rees.

MEMBERSHIP

The Committee on Membership held 22 meetings during the fiscal year 1930–1931.

The number of applications considered in the transaction of its work and a summary showing the action taken follow:

New applications pending, October 1, 1930	292
Transfers pending, October 1, 1930	94
Applications received during fiscal year 1930–1931	1529
Total applications handled during year 1930–1931	1915
Recommended for membership	1648
Transfers denied	4
Deferred	1
Withdrawn	44
New applications pending, October 1, 1931	179
Transfers pending October 1, 1931	39
Total applications handled during year 1930–1931	1915

Those recommended for membership were divided into the following grades:

Members	287
Transfers to Member	153
Associates	21
Transfers to Associate	1
Associate-Members	260
Transfers to Associate-Member	98
Juniors	338
Juniors (R5, Rule 1)	490
Total recommended	1648
Transfers	252
Total new members recommended	1396

During the fiscal year 1930–1931 the Membership Committee made the following recommendations:

Elections declared void	187
Resignations accepted	465
Dropped from membership	712
Total loss	1364

Respectfully submitted,

F. A. Waldron, *Chairman*
H. W. Butler
H. Webster
O. E. Goldschmidt
H. A. Lardner.

PUBLICATIONS

During the past year the Publications Committee has been seriously concerned with an attempt to hold its expenditures within its budget. An increase in the activities of the Professional Divisions resulting in an overwhelming number of papers has made careful selection of material for publication more essential and has retarded the prompt

appearance of some papers in the Transactions. It is unfortunate that the number of papers awaiting publication should have increased as a result of limited funds, in view of the fact that the editorial staff had caught up with its work to a point where the prompt publication, one of the benefits that had been expected to accrue from the new scheme of issuing Transactions in sections, became feasible otherwise. Because of limited funds the final publication of many papers ready for printing has been postponed, and sections of Transactions have appeared containing a greatly reduced number of papers.

A study of the costs of publication under the new scheme, based upon experience since 1926, has rendered valuable information on the amount of the expenditure to which the Society is committed in the acceptance of a paper for preprinting for a meeting with assignment of final publication to the Transactions. This information has been passed on to the Professional Divisions with a request that only papers of the highest quality be recommended for printing in Transactions. Further study of the problem of quality and quantity of papers is necessary, and it is hoped that cooperation between the Publication Committee and the committees of the Society which secure papers will result in a satisfactory solution of the problem.

Financial stringency also resulted in the publication of a 2-page *News* throughout the summer and a reduction in text pages in *Mechanical Engineering* from 80 to 72 for the months of July, August, and September. As a further measure of economy the Publications Committee recommended to Council that the printing of the Membership List for 1932 be omitted.

The Record and Index was issued as a section of the 1930 volume of Transactions upon the recommendation of the Publications Committee and with the consent of Council. This resulted in a saving in printing and distribution costs.

The Committee and the Staff have spent much time and study in the development of *Mechanical Engineering*. The size of type of the text pages was enlarged. A new format was worked out and decided upon and will be adopted with the January, 1932, issue. The functions and relationships of the A.S.M.E. periodical publications, the *News*, *Mechanical Engineering*, and Transactions, have been thoroughly discussed and are being brought to the attention of the members through the Local Sections. In the meantime, *Mechanical Engineering* is undergoing a change in editorial function that should enhance its value and significance.

The Committee is pleased to report the publication by the Engineering Societies Monographs Committee of the first of a series of books to be issued under a joint arrangement with the four Founder Societies, the Engineering Societies Library, and the McGraw-Hill Book Company; this is Nádai's "Plasticity," translated, with revisions and additions, from the German. The text was secured and sponsored by the Applied Mechanics Division.

The Mechanical Catalog was issued September 30 and contained data on the products of 488 companies, as compared with 574 in 1930.

The Engineering Index had reached the fortunate position of meeting current expenses when subscriptions were adversely affected by general business conditions. A committee of Council was appointed at the Hartford Meeting to make a thorough study of the Index.

Respectfully submitted,

F. V. Larkin, *Chairman* S. F. Voorhees
W. H. Winterrowd S. W. Dudley.
L. C. Morrow

PROFESSIONAL DIVISIONS

The activities of the Professional Divisions during the year have been especially significant. Five new developments were gotten under way, the most outstanding of which was the First National Meeting held by the Applied Mechanics Division at Purdue University. The program was coordinated with the summer meeting of the Society for the Promotion of Engineering Education. The success of the meeting gives promise of gathering into the Society all engineers interested in this field and also indicates that the Society will be recognized internationally as the American forum for activities in this field.

The Petroleum Division continued its splendid activities around Tulsa in cooperation with the Mid-Continent Section. It is expected that reports of tests conducted on steam equipment for drilling rotary-drilled oil wells will be published early in 1932. Two new developments occurred in the East under the auspices of the Division. The first was a Petroleum Refining Meeting held in Elizabeth, N. J., May 5 and 6, which was very successful and is resulting in the development of a very valuable standard for testing the efficiency of oil-refining tubular heat-transfer equipment. The other development was the holding of a one-day lubrication engineering meeting at Pennsylvania State College on May 22, which brought together more than 100 specialists in this field. This was the first time the Society has held a technical meeting solely on this subject.

Another new activity launched during the year was the work of the Process Industries Committee, which is developing a Division. Its program included a cooperative meeting with the American Institute of Chemical Engineers at Swampscott, Mass., in June.

The fifth new activity deals with maintenance engineering, which for the first time was given special prominence in divisional programs. A successful national meeting on maintenance engineering was held in Cleveland during April under the auspices of the Management Division as part of the Industrial Congress.

In addition to these meetings initiated during the year, the four-point program of the Professional Divisions continues to function as may be seen by the accompanying table. This table of the Divisions' activities shows papers secured and presented by them during the year. This does not include papers presented by them at usual Metropolitan Section meetings or Division progress reports, but does include papers for Section meetings in which the Division assisted financially.

Special Committee Activities

The Professional Divisions are gradually developing a fifth activity which might be called "Special Committees." Of these the following have been especially active during the year:

The Elimination of Waste Committee of the Management Division continued its work to stimulate industrial plants to hold elimination-of-waste campaigns, especially during the month of April. This year the Committee went to considerable expense to develop a system of posters and information which could be used by small companies in holding campaigns. This waste-campaign unit sold for the small sum of $3, and more then 130 companies made use of the unit in holding campaigns. During the year the Committee also compiled a booklet published by the Society called "Waste Materials Dictionary" which gave information on the use of waste items. Some 50 companies contributed items to the Dictionary.

The Oil-Engine-Power Cost Committee of the Oil and Gas Power Division continued its splendid work and again compiled a report on the cost of oil power. This Committee has the active cooperation of users all over the country. The Committee should be especially commended on its splendid report, which has met with wide approval.

The Pure Air Committee, which was organized this year through the aid of the Fuels Division, already has a subcommittee at work. The Committee is broadening the scope of work of the former Smoke Abatement Committee of the Fuels Division, and has upon it representatives of several other organizations. It gives promise of becoming a very valuable activity and one which will warrant the close cooperation of the whole Society.

The Manufacturers Committee of the Materials Handling Division has a subcommittee developing tentative standards for crawlers, locomotive cranes, and industrial cranes. This Committee has a splendid field of activities, which if given proper support by industry should accomplish valuable work. The Division also has a special committee at work on analyzing the field of various types of conveyors.

This year the Hydraulic Division's special committee on the translation of important foreign hydraulic papers began its work, which promises to be of considerable value.

The Petroleum Division has a number of committees active in the Mid-Continent Section and a newly formed committee which developed out of the Elizabeth meeting.

The Aeronautic Division has formed a committee to study wage-incentive practice in its industry. The Applied Mechanics Division has subcommittees stimulating developments in vibration, plasticity, and impact. The Wood Industries Division is forming a subcommittee to report on construction and design of doors, and also has a newly formed research survey committee.

Division Meetings

In addition to the new national meetings gotten under way, other Divisions have continued to function as usual.

The Printing Industries Division deserves special recognition for its meeting last March at the Government Printing Office in Washington in joint cooperation with the United Typothetae of America and the Government Printing Office. More than 500 attended this two-day meeting. The entire proceedings of the gathering were published by the Government Printing Office, as part of its splendid cooperation. This meeting was called "The Second Conference of Technical Experts in the Printing Industry" and it gave very definite evidence of the fact that the Printing Industries Division has succeeded in winning for itself recognition from the entire printing industry as the neutral forum for the discussion of its engineering problems. The

Division deserves a great deal of credit for the development of these conferences and for the recognition it has won the Society in this field.

The Aeronautic Division held its national meeting at Baltimore, Md., under the auspices of the Baltimore Section, Baltimore Engineers Club, and other local societies, which made possible the largest technical meeting ever held in aeronautics. As many as 50 papers were presented, covering almost every branch of aeronautics. The local program was especially well arranged and added much to the interest and pleasure of the meeting. During the year the Aeronautic Division also assisted Local Sections in Toronto, Buffalo, Cleveland, Philadelphia, and Detroit in holding meetings of more than local interest. In addition, the Aeronautic Division through the Metropolitan Section held a memorial meeting in the city of New York in February to honor the services rendered to aeronautics by the late Daniel Guggenheim, Glenn H. Curtiss, and Chance M. Vought. The program was arranged by the Division, but the meeting was a cooperative one in which several other societies participated. During the year the Division initiated the formation of a standards committee on aircraft safety inspection.

The Materials Handling and Management Divisions held their cooperative meeting in April in Cleveland as part of the National Industrial Congress. The Elimination of Waste Committee sponsored two sessions under the auspices of the Management Division; while the holding of a Maintenance Meeting as part of the Congress has already been mentioned. The Materials Handling Division held an extensive national meeting, covering its field very thoroughly. In spite of the depression the attendance at the Congress from the outside was larger than at the one held the year before in Chicago.

The Fuels Division held its fourth national meeting in February in Chicago in coordination with the Midwest Power Conference.

The Iron and Steel Division cooperated with the Detroit Section in a one-day meeting held in May. The Division also cooperated in the National Metal Congress held in Boston in September.

The Oil and Gas Power Division held its usual successful national meeting at the University of Wisconsin in June. This is the first time the Division has held a national meeting in the West, and its success is especially gratifying.

The Wood Industries Division held its first eastern national meeting in New York in October, 1930. Encouraged by the success of this meeting, the Division decided to hold its October, 1931, meeting at Winston-Salem, N. C. Although the membership of the Society is rather small in that neighborhood, the Division held a very successful national meeting, winning the hearty support and cooperation of the Southern Furniture Manufacturers Association. This gave promise of future benefit to the Society, as woodworking industries in the South have increased rapidly, even during the depression.

The Textile Division held a meeting jointly with the local engineering society and our Section in Providence, R. I., on October 6, and also a Southern Meeting as part of the Birmingham Spring Meeting.

The Machine Shop Practice Division cooperated in the National Metals Congress in Boston on September 22, and during the year has formed two promising subcommittees, one on foundry practice and the other on machine design. At the Boston meeting a conference was called on wear of metals, and the Division, jointly with the Iron and Steel Division, recommended the initiation of a research committee on the subject.

The Railroad, Power, and National Defense Divisions continued to function as adequately as their field demanded, using the regular Society meetings for their activities.

PROFESSIONAL DIVISIONS ACTIVITIES IN 1931—FOUR-POINT PROGRAM

[1] Includes Annual, French Lick, Birmingham, and Kansas City Meetings.
[2a] National Meeting, Baltimore, May, 1931; Toronto Meeting, March, 1931; Cleveland Meeting, Sept., 1931. [2b] and [2c] National Meetings were held with Management Congress. [2d] National Meetings were held with Metal Congress.
* All members are registered in National Defense Division.
NOTE: Table includes meetings held from October 8, 1930, to October 6, 1931.

The Railroad, Power, and National Defense Divisions continued to function as adequately as their field demanded, using the regular Society meetings for their activities.

Future Developments

During the year of 1932 it is expected that greater attention will be given to subcommittee activities of the Divisions, warranted by the increased financial support granted by Council. Several of the Divisions have already taken advantage of this by beginning to develop valuable subcommittee activities.

H. W. Brooks, *Chairman* C. B. Peck
W. F. Dixon W. A. Shoudy
P. T. Sowden

LOCAL SECTIONS

New Section

The members in Eastern Connecticut, with the approval of Council, organized the seventy-second Section of the Society, known as the Norwich Section. This was accomplished in time for their delegate to participate in the Local Sections Conference at the 1930 Annual Meeting. During the year this Section held four successful meetings.

Prospective Sections

Most of the Industrial areas of the United States have been provided with Local Sections which are now functioning. Sections at Ft. Wayne, Ind., Central Illinois, with headquarters probably at the University of Illinois, Nashville, Tenn., and Central Wisconsin, are probable developments in the near future.

Membership Chart

The number of meetings held by Sections during 1930–1931 is shown in Appendix I. This table also details the membership of the respective Sections on October 1, 1930, and October 1, 1931, the net increase, the percentage of membership increase, and the fact that 92 per cent of the entire membership is now residing within the territory of established Local Sections.

New Membership

The potential membership of the Society is enormous. Even with 20,000 members it can be conservatively stated that not more than half of the qualified mechanical engineers are enrolled. The most economical and dignified method of membership development would be for each of our 20,000 members to encourage one engineering associate, whom he knows to be well qualified, to file his application. If members would seriously undertake to do this, the membership could be doubled at little expense. The saving effected could be well applied to other Society services. Normal losses in membership include, on the average, 150 deaths, 350 resignations, and 800 who allow membership to lapse, making a loss of 1300 members or about 7 per cent.

Meetings

The Local Sections have cooperated in the development of National Meetings of the Society, particularly in the arrangements for the entertainment and plant visitations program at Birmingham, where the 1931 Semi-Annual Meeting was held; and for the National Regional Meetings held at French Lick Springs, Ind., October, 1930; at Hartford, Conn., June, 1931, and at Kansas City in September, 1931. Local Sections cooperated with the Professional Divisions in holding National Divisional Meetings as follows:

National Divisional Meetings, October 1, 1930–September, 1931

October 6–8, 1930	Petroleum	Tulsa, Okla.
October 16–17, 1930	Wood Industries	New York, N. Y.
October 22, 1930	Textiles	Greenville, S. C.
February 11–13, 1931	Fuels	Chicago, Ill.
March 16–17, 1931	Printing Industries	Washington, D. C.
April 13–16, 1931	Management and Materials Handling	Cleveland, Ohio
May 12–14, 1931	Aeronautics	Baltimore, Md.
June 15–16, 1931	Applied Mechanics	Purdue Univ., Lafayette, Ind.
June 23–26, 1931	Oil and Gas Power	Univ. of Wisconsin, Madison

In addition, Local Sections held 471 meetings of their own as shown in Appendix I.

Cooperation With Professional Divisions

The Sections also have availed themselves of each opportunity to cooperate with Professional Divisions by planning their programs to cover the subjects represented by the Professional Divisions; this practice is followed particularly in the larger Sections, like the Metropolitan and Philadelphia. Individual Sections have given fine support to many of the Professional Divisions by cooperating with them in various undertakings.

Scope of Service

The services available to members through Local Sections vary to some extent with the activity of the particular Section. The extent of activities is governed by conditions peculiar to the Section, the number of members, and its geographical location. A wide range of activities include the Employment Service, opportunities to study public speaking through classes arranged by the Local Section, opportunities for inspection of industrial plants, contacts with, and often, privileges of local engineering societies and clubs; opportunities for civic service, etc., besides the usual engineering meetings. Individual members with worthwhile ideas will usually find that their Local Executive Committee will welcome their interest and assistance on special committees.

Tours and Transportation

The Committee on Local Sections arranged for reduced fares to the Annual, Semi-Annual, and other national meetings of the Society during the year, thereby saving thousands of dollars to the members of the Society. Also, after the Council had accepted the invitation of the V.D.I. to have members of the Society participate in its Seventy-Fifth Anniversary Celebration at Cologne, June 26–30, 1931, it successfully planned, developed, and conducted a tour to Europe which was participated in by a large number of members and their wives, there being 85 from the United States in attendance at the Cologne Meeting of the V.D.I. Considerable international goodwill was built up through official visits by the party to several other societies. The Institution of Mechanical Engineers entertained at a tea in their rooms, and the party was also guests of officers of the Society of Civil Engineers of France, and of the Faculty of the École Centrale des Arts et Manufactures, which they visited. Thus the engineering societies of Germany, England, and France renewed their friendship with the A.S.M.E. Important industrial plants were also visited during the trip.

Elimination of Waste

Six sections cooperated with the Management Division in organising campaigns and meetings on the subject of "Elimination of Waste," as follows:

Section	Date of Meeting	Subject
Cleveland	April 13–17, 1931	National Division Meeting on Management, Materials Handling, and Maintenance
Detroit	November 17, 1930	Management as Related to a Medium-Size Plant
Hartford	April 7, 1931	Elimination of Waste in the Industrial Plant
Metropolitan	February 6, 1931	The Scope of Management in Our Future Business Development
Metropolitan	April 3, 1931	Product Design for Increased Utility and Improved Marketability
Philadelphia	October 28, 1930	Factory Management

Foreign Relations

In addition to the foreign relations developed in connection with tours, there has been built up and functioning for several years a service to foreign visitors and to members of our Society or members of other engineering societies traveling either in the United States or in other countries. Some idea of the extent of this service is contained in the résumé (Appendix II) covering the three-year period 1928–1931.

In addition to this service, from June 1, 1930, to October 1, 1931, 18 members of the Society were given letters of introduction to various organizations, societies, and plants in ten different countries of Europe. During the same period 27 members of the Society were given letters enabling them to gain admittance to various plants and works which they desired to visit. Prior to June, 1930, no records were kept of introduction service rendered the members of the A.S.M.E.

Employment

The administration of the Engineering Societies Employment Service, in so far as it pertains to our Society, was assigned by the Council during the year to the Committee on Local Sections. All Local Sections rendered special and valuable service at the beginning of the year 1931 by responding to the request of the A.S.M.E. Committee on Employment, of which Mr. Ralph E. Flanders was the Chairman, and which cooperated closely with the President's Emergency Committee for Employment in accordance with Col. Arthur Wood's personal appeal to the members of the Society at the 1930 Annual Meeting. Excellent progress was made during the year by the reestablished Volunteer Employment Committee, composed of members of the four Founder Societies out of employment. These men visited various concerns to urge upon them the employment of engineers and jobs were located as a result of their activity. Also, more than 30,000 letters were sent to various industrial concerns in the United States, soliciting opportunities for employment. During the year the Service placed 559 members in positions, and 231 non-members were placed in positions for which we could not find members with the necessary qualifications, making a total of 790 placements. These were divided as follows:

New York:	Members	391
	Non-Members	110
Chicago:	Members	63
	Non-Members	47
San Francisco:	Members	105
	Non-Members	74

However, because of the falling off in positions open, the income derived by the Employment Service from contributions made by members placed in positions was so reduced that it was necessary for the four societies not only to renew on April 1, 1931, their financial support of the Service, but to increase the budget by 50 per cent. Plans are progressing for the continuation during the ensuing year of the Employment Service with its three offices in Chicago, New York, and San Francisco, which will require finances of double the amount previously contributed. Members generally will be requested to be particularly alert to find opportunities for the very large number of members of the Society out of employment. The coming winter threatens to be one of the most difficult periods in the history of our country and a corresponding degree of importance should be attached to the Employment Service in its efforts to assist members to "help find a job for an engineer."

Mid-West and Mid-Continent Offices

The Mid-West Office located at 205 West Wacker Drive, Chicago, Ill., and the Mid-Continent Office, 503 Tulsa Bldg., Tulsa, Okla., have made much progress in rendering service to the Student Branches and Local Sections in those areas of the country. (See Appendixes III and IV.)

Local Sections Visited by the Committee

During the year President Wright has either visited or has definitely scheduled a visit to every Local Section of the Society. This is the first time that this will have been accomplished. Other presidents have made notable contributions in this direction and have visited a majority of the Sections, but President Wright will be the first to meet with all of them. In addition, the Committee on Local Sections visited Local Sections as shown in Appendix V.

Local Sections Financial Policy

The Local Sections Conference of 1930 adopted a recommended financial policy of the Society pertaining to Local Sections. Copies may be obtained from the Secretary's office if desired.

Harry R. Westcott, *Chairman* — Jiles W. Haney
Charles W. Bennett — William Lyle Dudley.
James M. Todd

APPENDIX II VISITORS FROM FOREIGN COUNTRIES TO A.S.M.E., JUNE, 1928, TO SEPTEMBER 30, 1931

Visits were made to the A.S.M.E. by 208 people from 22 countries, as follows:

Australia	1	Austria	5	Belgium	1
China	1	Czechoslovakia	16	Denmark	3
England	62	France	19	Formosa	1
Germany	64	Holland	7	Hungary	1
Italy	4	Japan	4	Mexico	2
Norway	4	Poland	2	Roumania	1
Russia	1	Scotland	3	Sweden	3
Switzerland	3				

Of the 62 visitors from England, 34 were students of The Liverpool University, sponsored by the Liverpool Engineering Society, Liverpool, England. Each of the past three summers approximately 12 of these students have worked in the engine room of a transatlantic liner, and in accordance with our arrangements have visited several power or other plants in New York and vicinity during the period the steamship was in New York harbor. Their interest in different phases of engineering is shown by the following figures as to the type of plants they requested permission to visit:

11 electrical engineering
11 mechanical engineering
9 civil engineering
1 general engineering
1 internal combustion engine
1 naval architecture

According to our records Germany sent 64 visitors, of which practically one-third were young engineering graduates sponsored by The German Students Cooperative Association. We have aided a number of them to obtain employment in the United States.

For each visitor, we prepared letters of introduction to various companies whose plants and factories they desired to visit.

The number recorded, 208, represents only a portion of the number of visitors served. In many instances when we arranged inspection trips for a party of foreign engineers we kept a record of the leader of the party only. We have served several visitors for whom no record was entered. In the past three years this Society has served possibly 300 engineers of other countries.

APPENDIX I MEMBERSHIP IN LOCAL SECTIONS, OCTOBER 1, 1931

Section	Membership Oct. 1, 1930	Oct. 1, 1931	Increase	Per cent	Meetings, 10/30-10/31

APPENDIX III MID-WEST OFFICE

The first field office of the Society was established in Chicago, Ill., in October, 1929. In April, 1930, R. R. Leonard, a member of the New York staff, was transferred to the newly established office to act as a representative of the Field Department in the following states covered by the office: Illinois, Indiana, Iowa, Kansas, Kentucky, Michigan, Minnesota, Missouri, Nebraska, Ohio, and Wisconsin. Within these states 21 Local Sections and 27 Student Branches function. They were visited and given cooperation in working out the details of operation of this new venture of the Field Department.

In addition to personal visits contacts with each group were made on numerous occasions by telephone or correspondence. Stress has been laid on the facility of a nearby branch office of the Headquarters organization to render prompt assistance. The intimate contact of the Mid-West Office with the headquarters staff greatly facilitates action in regard to the problems of the Local Sections and Student Branches.

Local Sections have been aided in the preparation of local programs, as well as in their participation in regular Society and Division meetings. The headquarters staff has been assisted in the operation of meetings within the territory of the Mid-West Office. Student Branches have been helped in program set-ups, speakers have been obtained, and advice on general activities has been supplied. Through intimate contact with each of the groups, Local Section and Student Branch, it has been possible to use the experiences of one group to the advantage of other groups. Information on the activities of individual members has been obtained, and as a result members capable of offering valuable committee assistance have been discovered and some of these have already been enlisted for service. New activities of Professional Divisions have been initiated as a result of information uncovered through this more intimate contact with organized groups.

In the Chicago area especially, engineering and other organizations, as well as individuals, have found the Mid-West Office a convenient channel through which information on Society activities and general engineering information may be obtained. The office has received a number of calls for Society publications, and in a few instances valuable time has been saved through its ability to supply them immediately.

Local Sections and Student organizations alike have expressed enthusiastic approval of this new service. They have accepted it with obvious pleasure and have shown marked willingness to offer suggestions for improvement of conditions among all such groups. A few Sections have even asked for an extension of the service by placing the mid-west representative in temporary quarters within the Section for periods ranging from one week to two months. Others have expressed the opinion that a beneficial move would be to establish offices of the character of the Mid-West Office in other parts of the country.

The Mid-West Office has taught the organized groups within its territory that the close proximity of the office is favorable to quick interchange of information, and they have expressed the desire to have the greatest possible service through that point.

There is no doubt that the new service has effected economies, but merely from the standpoint of closer contact with the organized groups within the territory covered by the office and the increased good-will resulting from the more intimate contacts, it would seem that the Standing Committee on Local Sections has been more than justified in its creation of the Mid-West Office.

APPENDIX IV MID-CONTINENT OFFICE

The activities of this office are concerned principally with the problems of the petroleum industry. The Steam Subcommittee of the Production Committee has compiled and sent in to the Mid-Continent Office its report on "Tests on Steam Equipment Used in Drilling a Rotary Drilled Oil Well" and a second report on "Tests on Slush Pumps and Boilers Used in Drilling a Rotary Drilled Oil Well." These two reports, as well as all others on rotary drilling, will be issued under the auspices of the recently appointed Special Research Committee on Rotary Drilling of Oil Wells. A report by the Electrical Subcommittee on Petroleum Production was also completed.

The Fluid Meters Subcommittee has completed the layout plans for tests to determine the accuracy of existing coefficients and correction factors for viscosity, gravity, and temperature of oils flowing through orifices and flow nozzles. The necessary equipment needed to perform these tests, which will cover a period of two years, is now being assembled through the generous cooperation of several manufacturing companies. Prof. W. H. Carson, Head of the Department of Mechanical Engineering at the University of Oklahoma, will have charge of conducting the tests.

The Unfired Pressure Vessel Committee has sent in to the Boiler Code Committee its recommendations for the use and construction of unfired pressure vessels used in the petroleum industry, as well as its views on the revised draft pertaining to unfired pressure vessels.

The Automatic Pumping Station Committee and the Economic Analysis of Automatic Pumping Station Committee designed and constructed an automatic pumping station for use on oil pipe lines, which was exhibited at the Seventh International Petroleum Exposition at Tulsa, Okla., in October, 1930. As a result of this experimental station six such stations have been put into operation during the year. Two joint meetings have been held since then at which operation problems of the latest automatic stations were discussed and corrections suggested. Several changes and improvements of equipment will be made as a consequence of these meetings. The Economic Analysis Committee has collected data on the salvage values of various equipment, insurance, and tax rates. The Committee will compile, from reports sent in from several automatic stations, a thorough report on improvements made in equipment and operation since the exhibition at the oil show.

A campaign has been started among the pipe-line companies to have each appoint a Waste Elimination Committee and to have a representative on the A.S.M.E., Mid-Continent Section, Waste Elimination Committee.

Members are beginning to make use of this office as a medium for obtaining information pertaining to technical problems confronting them in their business.

HARRY R. WESTCOTT, *Chairman* J. W. HANEY
C. W. BENNETT W. L. DUDLEY.
J. M. TODD

Due to extensive visits to Local Sections by the President this year, the Committee considerably curtailed its usual travel.

AWARDS

This Committee has met nearly every month, except during the summer season.

In order to read all papers submitted for the various awards, the Committee arranged a new plan whereby the best papers of each group were selected by a member and circulated to other committee members.

The Committee made the following recommendations to Council for the Awards for 1931:

(1) The A.S.M.E. Medal to Albert Kingsbury for his research and development work in the field of lubrication.

(2) The Melville Medal to A. E. Grunert for his paper entitled "Comparative Performance of a Pulverized-Coal-Fired Boiler Using Bin System and Unit System of Firing."

(3) The Junior Award to M. K. Drewry for his paper entitled "Radiant-Superheater Developments."

(4) The Charles T. Main Award to Robert E. Klise of the University of Michigan for his paper on "Interchangeability—Its Development and Significance in Industry."

(5) One Student Award to Jules Podnossoff of the Polytechnic Institute of Brooklyn for his paper entitled "Pressure and Energy Distribution in Multi-Stage Steam Turbines Operating Under Varying Conditions."

The Committee recommended only one Student Award this year, due to the caliber of the eligible papers received.

The Committee announces that the subject determined for the Charles T. Main Award for 1932 is as follows: "Apprenticeship and Vocational Training—Their Effect on Industry and Public Life."

It is fortunate for students of engineering, in need of financial assistance, that the Max Toltz Fund has been available. The demand for loans has been unusually heavy this year and the Committee approved fourteen loans to students from the Fund. These loans amounted to $2625.00, more than twice as much as was loaned last year.

The Committee has given some thought to a codification of its practice in judging papers and has a statement of this in preparation. It is hoped that this statement will also be of value to the Professional Divisions as a guide to them in recommending papers to the Committee on Awards.

The statements in the several publications of the Society describing the various awards have been studied and harmonized by the Committee this year.

The will of the late Worcester Reed Warner provided a generous bequest for a medal to be known as the Worcester Reed Warner Medal. It is to be a gold medal to be bestowed on the author of the most worthy paper received, dealing with progressive ideas in mechanical engineering or efficiency in management. The Committee has selected an artist and will soon be ready to have the dies made. The hearty cooperation of Mrs. Warner and Mr. Swasey in assisting the artist and the Committee is much appreciated.

Respectfully submitted,

H. L. Seward, *Chairman*
A. M. Greene, Jr.
K. H. Condit
F. L. Eidmann
W. L. Batt.

CONSTITUTION AND BY-LAWS

The Committee on Constitution and By-Laws serves in an editorial capacity where amendments to the Constitution, By-Laws, and Rules are required or new policies necessitate changes.

The most important change made during this past year is in the amendment to the Constitution affecting the initiation fees in the several grades, approved by the entire membership on a ballot which closed November 10, 1930. The amendment went into effect on its announcement at the Annual Meeting in December, 1930. The new wording follows:

Article C5 Fees and Dues

Sec. 1 The initiation fee for membership in each grade shall be:

Member	$35*
Associate	35*
Associate-Member	25†
Junior	10†
Promotion from Junior‡ to Associate-Member	15
Promotion from Associate-Member to Member	10
Promotion from Junior to Member or Associate	25

* Formerly $25.
† No change.
‡ Promotion from Junior to higher grade, formerly $10.

With the recommendation of the committees concerned with membership, publications, and Local Sections, the Council has reworded part of B14 (3) in order to provide for continuing to send the *A.S.M.E. News* to members after the expiration of the three months' limit for payment of dues (in advance). Other publications are not mailed. Other proposals for rewording the By-Laws have been submitted to Council, but not yet acted upon.

The Publications Committee as a matter of economy recommended, and the Council approved, the future publication of the Constitution, By-Laws, and Rules as a separate pamphlet. No new edition has been printed since that of the Record and Index of 1929.

At the request of the Council the Committee has under consideration the editing of the By-Laws and Rules to bring into better relation certain sections of the rules for various committee work, and to condense other sections. However, this work is not completed, as all Standing Committees of the Council have in process the review of their own special rules; considerable headway has been made, but the work must be carried forward into the new administrative year.

Respectfully submitted,

A. D. Blake, *Chairman*
Thos. C. McBride
R. S. Neal
H. H. Snelling
P. R. Faymonville.

RELATIONS WITH COLLEGES

Student Branches were established at the University of Alabama, Tuscaloosa, Ala., Harvard University, Cambridge, Mass., and the University of South Dakota, Vermilion, S. D., during the year, bringing the total number of Student Branches to 108.

There were 867 Student Branch meetings reported during the school year 1930–1931, an increase of 230 over last year, or 36 per cent. President Wright visited 45 Student Branches during the school year 1930–1931 and 17 Branches in the fall of 1931.

Membership in the Student Branches increased by 660 members over the 1929–1930 school year. Twenty-two joint meetings with Local Sections were held.

Student Branch Conferences were held at the Annual Meeting, the Birmingham Meeting, and the Kansas City Meeting. These conferences were well attended. The Birmingham Conference and the program therefor was arranged by a special committee appointed for the purpose. More than 125 undergraduates were present to hear several excellent papers presented by members of Student Branches.

At the Birmingham Semi-Annual Meeting of the Society an even more important event occurred. Mr. M. C. Maxwell, Chairman of the Committee this year, presented a new policy for Student Branch activities. This policy had been approved at a meeting of the Committee held in New York early in April. The policy was approved in principle by Council. It provides that undergraduates be admitted to a grade of membership designated "Student Member," that application for this grade be made upon a regular form provided by the Society, and that a fee of $3 accompany this application. The application, which must bear the endorsement of the Honorary Chairman, is passed upon by the Membership Committee of the Society and then by Council in the same way as all other applications. Upon election, the Student is provided with a regular Membership Card bearing the designation "Student Member." The Student is also provided with a Student Membership badge bearing the insignia of the Society. Each Student Branch having fifteen or more "Student Members" is entitled to receive reimbursement for necessary expenses to the amount of $25 per annum and each continues to receive the Transactions of the Society as issued and annually a bound volume of Transactions. One copy of *Mechanical Engineering* is sent for each fifteen Student Members, and each Student Member receives semi-monthly a copy of the current issue of the *A.S.M.E. News*. The latter will be developed to provide sufficient space to record the interesting events and progress of the Student Branches and their members. The plan provides for mileage for one member of each Student Branch to a Regional Student Branch Conference, and for transfer to Junior Membership in the Society, upon the endorsement of three Faculty members, with suspension of the first year's dues.

The Council decided at its Hartford meeting to provide $2850 as a special fund to inaugurate the new policy in fifteen colleges in the South (east of the Mississippi River). President Wright appointed Mr. Lewis F. Gordon of Atlanta, Georgia, to membership on the Committee on Relations with Colleges for a five-year period, thereby giving further recognition to the southern Student Branches and assuring them of active leadership by the Committee. As the year closes, Chairman Maxwell, Mr. Gordon, and Ernest Hartford, Secretary to the Committee, have arranged an itinerary which will bring them to each of the fifteen colleges to consult with their faculties and officers during October, 1931.

Respectfully submitted,

Maxwell C. Maxwell, *Chairman*
D. B. Prentice
E. F. Church, Jr.
Wm. L. Abbott
Lewis F. Gordon.

EDUCATION AND TRAINING FOR THE INDUSTRIES

Meetings of the Committee were held during the Annual Meeting, and a proposed joint meeting with the Management Division was discussed with President-Elect Wright.

The Committee considered it unwise to attempt to survey training processes in industry under present conditions. The papers arranged for the December, 1930, meeting were:

(1) "Apprentice Training in Virginia," by C. F. Bailey, Newport News Shipbuilding and Dry Dock Company.

(2) "The Apprentice Training Movement in Wisconsin Industry," by Harold S. Falk, Vice-President and Works Manager, The Falk Corporation.

(3) "Opportunities for Aviation Training," by J. S. Marriott, Chief of Inspection Service, Aeronautics Branch, U. S. Department of Commerce.

Mr. Charles H. Colvin, President, The Pioneer Instrument Company, Brooklyn, New York, presided at this meeting. About 200 were in attendance.

The following program was arranged for the Hartford Meeting, Monday, June 1, 1931:

(1) "Training Foremen to Deal With Human Problems in Industry," by John A. McCarthy, State Supervisor of Trade and Industrial Education, New Jersey Department of Public Instruction.

(2) "Training Apprentices and Foremen," by Frances Perkins, Industrial Commissioner, New York Department of Labor.

A joint program with the Management Division has been arranged for the 1931 Annual Meeting, as follows:

(1) Opening Address, by Roy V. Wright, President of the Society.

(2) "Foremanship Training," by U. J. Lupien, Cheney Brothers.

(3) "Modern Industrial Training," by George A. Seyler, Lunkenheimer Company.

Respectfully submitted,

R. L. Sackett, *Chairman*
D. C. Jackson
John T. Faig
Harold S. Falk
C. F. Bailey
S. S. Edmands } *Associate-Members.*
W. S. Conant }

LIBRARY

The Library Committee represents the A.S.M.E. on the Library Board of the Engineering Societies Library. The report of the Library Board for 1930 shows that there has been no lessening in the use of the library during the depression, but that, on the contrary, there has been a slight increase.

More than forty thousand members of the Founder Societies used the Library during 1930. Forty per cent of these were non-visitors, assisted by loans of books, photoprints, and searches. Twenty per cent more photoprints were called for than in 1929.

Gifts from members of the Founder Societies and other friends numbered 12,517 books and pamphlets. The main collection was increased by 7418 volumes and now contains 139,916 volumes and pamphlets.

During the year a new bookstack was erected, which eliminated serious overcrowding and provided some room for growth.

At the annual meeting of the Library Board in January, 1931, the Chairman of your Library Committee was elected Chairman of the Library Board.

Respectfully submitted,

Alten S. Miller, *Chairman*
George F. Bateman
E. P. Worden
Walter M. Keenan
Calvin W. Rice, *Secretary.*

RESEARCH

The Standing Committee on Research reports 29 cooperative research committees wholly or jointly sponsored by the Society on October 1, 1931. Two new committees were organized during the year, one on rotary drilling of oil wells and the other on critical pressure steam boilers.

It is gratifying to note that although a severe business depression existed throughout the year the total contributions from industry and other sources to the various committees and the expenditures by these committees were slightly greater than those of the previous record year—$53,000 being contributed and $51,000 spent. This money covered the salaries of 25 research workers on whole or part time at 10 institutional laboratories, and materials and special equipment in several cases.

Committee Activity

The personnel of the 29 committees totals 445 men, 45 per cent of whom are non-members of the Society. Most of these committees have held one or more business meetings during the year; in all a total of 43 meetings were held. In addition, they have sponsored either alone or jointly 10 technical sessions for the presentation of their reports and related papers at meetings of the A.S.M.E. and other societies.

Experimental investigations are being financed either in whole or in part at the following institutions: National Bureau of Standards, Washington, D. C., and Columbus, Ohio; U. S. Bureau of Mines, Pittsburgh, Pa.; Massachusetts Institute of Technology; University of Michigan; Union College; University of Illinois; Ohio State University; University of Minnesota; and Carnegie Institute of Technology. Several field investigations have also been under way. Many more institutional and industrial laboratories have been cooperating with the committees without financial assistance.

Financial Record

Contributions to the various programs from industry, Engineering Foundation, and similar sources have totaled more than $53,000 this year as against $48,000 last year. The committees have thus continued to maintain 25 full- and part-time research workers on their programs. Expenditures for this work amounted to $51,000, somewhat more than last year. The Society, in addition, contributed about $14,000 for administrative and secretarial assistance this year toward the organization, maintenance, and development of this cooperative research work. It should be noted that the ratio between industrial contributions and Society contributions still continues to be better than three to one.

Publications

Technical progress reports on their work and related papers have been presented by the committees and published by the Society and other organizations throughout the year. These filled 39 pages of *Mechanical Engineering* and 387 pages of the Transactions alone. As was done last year, these papers are being bound together in a single volume for sale under the title "A.S.M.E. Research Reports and Papers, 1931." In addition, the following separate Research publications developed by the committees were published for sale by the Society:

Fluid Meters, Part 2—Description of Meters
Dynamic Loads on Gear Teeth
Bibliography on Deterioration of Condensing Equipment
Supplement to a Bibliography on the Effect of Temperature on the Properties of Metals.

The Bibliography on Riveted Joints being prepared by A. E. R. deJonge for the industry is in printer's proof form and now comprises over 500 selected and abstracted references.

Prof. W. M. Coates reports that the manuscript of the bibliography and monograph on the Stress Analysis of Pressure Vessels is about completed.

Items of current interest on the activities of the various committees have appeared from time to time in the *A.S.M.E. News*.

Approved Research Publications of the A.S.M.E. The following research publications have been issued by the Society to date:

Bibliography on Riveted Joints
Bibliography on Mechanical Springs
Report on Fluid Meters, Part 1—Their Theory and Application (Third Edition)
Bibliography on Effect of Temperature on Properties of Metals
Bibliography on Woods of the World—Exclusive of the Temperate Region of North America and with Emphasis on Tropical Woods
Bibliography on Cutting of Metals
Fluid Meters, Part 2—Description of Meters
Dynamic Loads on Gear Teeth
Bibliography on Deterioration of Condensing Equipment
Supplement to a Bibliography on the Effect of Temperature on the Properties of Metals.

International Cooperation

The Research Committee can report considerable progress in bringing about closer contact between the Society's research committees and similar groups abroad, particularly through the Institution of Mechanical Engineers and the Department of Scientific and Industrial Research in England and through the Verein deutscher Ingenieure in Germany. Reports of collateral work are exchanged regularly, and the men active in these fields are being brought closer together through international conferences as well as personal visits. These contacts are profitable to the members of the A.S.M.E. as well as to those of the foreign societies in many ways.

Committee Reports

Lubrication. A. E. Flowers, Chairman. The experimental studies at the Bureau of Standards have been continued during the year with three full-time and several part-time workers in the employ of the

Committee, an arrangement made possible by contributions totaling more than $4000 from industry and Engineering Foundation. These studies include (1) further investigation of viscosity under high pressure, (2) journal bearing investigations, and (3) oiliness research. Three other laboratories have cooperated with the committee, namely, (*a*) Pennsylvania State College, on experimental test of hydrodynamic theory of lubrication, (*b*) Kingsbury Machine Works, on pressure distribution in oil films, and (*c*) Research Department of Westinghouse Electric and Manufacturing Company, on waste-packed bearings, ring oiling, and forced lubrication.

A direct result of this activity was the Annual Meeting session held on December 5, 1930, at which Mr. Albert Kingsbury read his paper "On Problems in the Theory of Fluid-Film Lubrication With Experimental Method of Solution," and the Fifth Report of the A.S.M.E. Special Research Committee on Lubrication was presented.

Preparations for a similar session at the 1931 Annual Meeting are now in progress, and it is known that papers on "Optimum Conditions in Journal Bearings" will be read by Mr. Kingsbury and on "Pressure Distribution in Oil Films of Journal Bearings" by Messrs. S. A. McKee and T. R. McKee.

The Chairman published a paper on "Modern Lubrication Studies" in the May 26, 1931, issue of *Power*.

Mr. L. J. Bradford, a member of the Committee and Professor of Machine Design, Pennsylvania State College, read a paper on "Bearing Design in the Light of Oil-Film Pressure Investigation" at the Lubrication Meeting of the Lubrication Engineering Committee of the A.S.M.E. Petroleum Division, State College, Pa., May, 1931. He will also present a paper on "Oil Film Pressure" at the coming Annual Meeting.

In July, 1931, the Committee was represented at the International Congress on Lubrication, Strasbourg, France, by Mr. Winslow H. Herschel, a member of the staff of the Lubrication Section of the National Bureau of Standards.

Fluid Meters. R. J. S. Pigott, Chairman. "Fluid Meters, Part 2, Description of Meters," has been completed and published by the Society. Draft of Part 3, on the "Influence of Installation," was fully discussed by the Committee at its meeting on September 24, in Pittsburgh, Pa., and will be revised further.

The day following this meeting, the members of the Committee met with the Gas Measurement Committee of the American Gas Association. They discussed the revision of the table of coefficients now employed by the American Gas Association and arranged for joint review and promulgation of future tables.

During the summer months a subcommittee was organized in the Tulsa area to conduct tests to determine the accuracy of existing coefficients and correction factors for viscosity, gravity, and temperature in the measurement of oil. Two meetings have been held. A program has been laid out and contributed equipment is now being set up at the mechanical engineering laboratory of the University of Oklahoma under the direction of Prof. W. H. Carson. A delegation from the A.S.M.E. Special Research Committee on Fluid Meters attended the annual Southwestern Gas Measurement Course held at the University of Oklahoma in Norman, Okla., April 21–23.

The Special Research Committee on Fluid Meters will hold a session at the 1931 Annual Meeting of the Society. Two papers have been prepared for presentation at this session.

Thermal Properties of Steam. Alex Dow, Chairman. Throughout the year, the experimental part of the Committee's program was continued at the Massachusetts Institute of Technology under Dr. F. G. Keyes and Mr. L. B. Smith, and at the Bureau of Standards under the immediate direction of Dr. N. S. Osborne with Messrs. H. F. Stimson, D. C. Ginnings, and E. F. Fiock assisting.

Dr. Keyes and Mr. Smith have spent the greater part of the year designing and constructing a new stainless-steel bomb with which to make check measurements on the volume of saturated and superheated steam. In a similar way the experimenters under Doctor Osborne have designed and completed the construction of a new steel calorimeter. Early in the coming year it is expected that measurements of saturation pressures and temperatures up to 2500 lb. per sq. in. will be begun with this apparatus, and the design of a new flow calorimeter for superheat measurements will be started.

No international meeting was held this summer, but correspondence has passed between members of the Committee and the laboratories in Great Britain, Germany, and Czechoslovakia which are at work on this problem and others interested in the results attained. One of the subjects of discussion was the date of the Third International Steam Conference, which is to be held in the United States. The date finally decided upon is September 12–17, 1932.

The usual Steam Tables Research Session was held during the 1930 Annual Meeting of the Society at which papers and reports were presented by Messrs. Keyes, Smith, Osborne, and Keenan.

In September, 1931, the Society published an inexpensive abridgment of the Keenan "Steam Tables and Mollier Diagram," intended particularly for the use of engineering students and publishers desiring to reproduce these tables in abstract.

Strength of Gear Teeth. Ralph E. Flanders, Temporary Chairman. The main Research Committee appointed Mr. R. E. Flanders to the chairmanship to fill the vacancy caused by the death of Mr. Wilfred Lewis.

"Dynamic Loads on Gear Teeth," a complete report of the Committee's investigation at the Massachusetts Institute of Technology during the past five years, was finished during the year by Prof. Earle Buckingham and published in pamphlet form by the Society, in July, 1931.

Cutting of Metals. F. C. Spencer, Chairman. This has been a year of reorganization and readjustment for this special research committee. At its December, 1930, meeting, an executive committee consisting of the three officers was created, and chairmen of subcommittees on Bibliography and Correlation, Cutting Fluids, Metal Cutting Materials, Physics of Cutting Metals, and Properties of Materials, were appointed or reappointed.

The Subcommittee on Cutting Fluids presented a preliminary report prepared by Prof. O. W. Boston, who is in charge of a part of this investigation in progress at the University of Michigan. This report, in the form of a paper, was presented at the Hartford Meeting of the Society in June, 1931. At this session Mr. T. G. Digges of the Bureau of Standards also read a paper, entitled "The Influence of Chemical Composition on Heat Treatment of Steel Forgings on Machinability With Shallow Lathe Cuts."

Chairman Nichols spent three months in Europe during the spring and summer. While there, he visited a number of manufacturing plants in Germany and gathered data for the Committee. Before sailing, he resigned the chairmanship of the Committee in favor of Mr. F. C. Spencer.

Before the close of the fiscal year additional funds were made available to the Subcommittee on Cutting Fluids, Mr. Carl Oxford, Chairman, to permit the continuance of the experimental program at the University of Michigan under Professor Boston.

At the December, 1931, Annual Meeting of the Society, the Committee will hold a joint session with the Machine Shop Practice Division at which a report of the Subcommittee on Metal Cutting Materials will be presented.

The Committee has caused to be translated, and is revising for publication by the Society, a book by Prof. K. Gottwein on "Kühlen und Schmieren bei der Metallbearbeitung."

A comprehensive Bibliography on Milling, being compiled by Prof. J. D. Hoffman at Purdue University, is nearing completion.

Mechanical Springs. J. R. Townsend, Chairman. The chairman and secretary visited personally the prominent spring manufacturers to determine the scope of their spring problems and to ascertain what the Committee might do to help solve them. This survey brought out the need for more information on the fatigue qualities of full-size springs, for the determination of correct spring constants for those materials most widely used in springs, and for the standardization of a new code of design employing these spring constants. Two of the large spring manufacturers have offered their laboratories for the fatigue tests. The program covering railroad-size helical springs has been completed and tests have been begun in these laboratories. A similar program of fatigue tests on wire springs is being prepared. In December, 1930, and in June of this year, Prof. M. F. Sayre reported before meetings of the Society the progress of his investigation on certain characteristics of spring materials, which is being financed by the Committee at Union College. Prof. J. B. Reynolds, at Lehigh University, has continued his investigations of conical springs and will present a report in December, 1931. The Committee's bibliography of current springs literature has continued to be distributed to members and financial contributors.

Effect of Temperature on the Properties of Metals. H. J. French, Chairman. (Joint Committee with A.S.T.M.) The outstanding contribution of this Committee for the year was the Symposium on the Effect of Temperature on the Properties of Metals held during the June, 1931, Annual Meeting of the American Society for Testing Materials in Chicago. This symposium amounted to an authoritative statement of the engineering needs for metals to withstand high temperatures and the properties of the available metals. Some fifty authors contributed 28 papers. These papers with discussion will be printed in an 800-page bound volume and sold by the two societies. Additional papers were contributed by the Committee to the meetings of the two societies during the year. The A.S.M.E. also published for the Committee an up-to-date "Supple-

ment to the Bibliography on the Effect of Temperature on the Properties of Metals."

Prof. H. F. Moore of the University of Illinois has submitted a report of fatigue tests on a low-carbon steel at high temperatures, an investigation financed by the Committee. Progress has been made by the various industrial laboratories cooperating with the Committee in studies of high-temperature effects on mechanical properties and structural stability of cast, wrought, and stainless steel. Progress can also be reported in the development of a test code for high-temperature tension tests.

Nearly half of the required amount of $20,000 has been subscribed by the National Electric Light Association, the American Petroleum Institute, the Engineering Foundation, and a group of alloy casting manufacturers to the support of a proposed enlarged research program for the Committee.

Condenser Tubes. A. E. White, Chairman. The Committee's progress report on the study of the effect of air both in the entrained and dissolved condition upon condenser-tube deterioration was presented at the Annual Meeting, December, 1930. Under the direction of Mr. B. Houghton, Vice-Chairman of the Committee, a number of examinations have been made of these conditions in the condensers of several steam generating stations according to a procedure set up by the Committee. Further experimental work has also been carried on for the Committee.

A comprehensive bibliography of the causes and prevention of corrosion and other forms of deterioration in condenser tubes was presented to the Society and published in pamphlet form during the year. The Committee will present a progress report at the 1931 Annual Meeting.

Boiler Feedwater Studies. S. T. Powell, Chairman. (Joint Committee with A.B.M.A., A.R.E.A., A.S.T.M., A.W.W.A., and N.E.L.A.) The Committee, resuming activities after the recovery of the Chairman from serious illness, has concentrated on research studies on priming and foaming of boiler waters, and on the standardization of water analysis applicable to boiler feed and other industrial uses.

The Committee, in April, 1931, completed negotiations whereby a fellowship was established at the Ohio State University under the direction of Prof. C. W. Foulk, to continue the studies on priming and foaming of boiler waters. Professor Foulk will present a paper at the Boiler Feedwater Session at the December, 1931, Annual Meeting of the Society.

Subcommittee No. 8 on the Standardization of Water Analysis Methods has been reorganized under the chairmanship of Mr. C. H. Fellows, and close contact has been established with similar groups in the American Society for Testing Materials, the National Electric Light Association, and the American Water Works Association. To facilitate the work of formulating standard test methods, the Committee has established a fellowship at the University of Michigan. Mr. Fellows' Subcommittee will present at the coming Annual Meeting a progress report including studies of methods for determining alkalinity of boiler water.

Report No. 21 of the Subcommittee on Bibliography was distributed in May, 1931, to Committee members and to contributors.

Boiler Furnace Refractories. W. A. Carter, Chairman. The Committee held a session at the 1930 Annual Meeting of the Society at which papers were presented on "Comparative Resistance of Refractories to Coal-Ash Slags," by R. K. Hursh, "Action of Slags on Firebrick and Boiler Furnace Settings," by T. A. Klinefelter and E. P. Rexford, and "Furnace-Gas Compositions and Temperatures in Underfeed-Stoker-Fired Boilers and Their Effect on Boiler Settings," by Albert C. Pasini and Edward M. Sarraf. The authors of the third paper are not members of the Committee.

The U. S. Bureau of Mines published Bulletin No. 334 on "A Study of Refractories Service Conditions in Boiler Furnaces"—a summary of papers and reports of work done for the Committee during the past five years. Copies of this publication were distributed to the members of the Committee and to the contributors.

A special report on "The Effects of Cahokia, Trenton Channel, and Lowellville Slags on Their Respective Bricks Under Reducing and Oxidizing Atmospheres," by E. P. Rexford and E. J. Vachuska also was distributed to the same groups for their information.

Tests have been continued at the Columbus Branch of the National Bureau of Standards by E. P. Rexford, A.S.M.E. Research Associate, with the assistance of Mr. Vachuska, under the direction of Mr. T. A. Klinefelter, superintendent of the station. These include an investigation of power-house refractories, studies of samples from the Connors Creek Station, Roseville Brick Plant, Deepwater Installation, and others; studies on the multiple-component system; on power-house samples; on firing brick and slag samples in reducing atmospheres; and on the effects of reducing atmospheres on the slag action on firebrick.

The laboratory slag tests at the Battelle Memorial Institute include reports on various refractories (ST1 to ST8) with Lowellville, Cahokia, Chicago, Nanticoke, Peoria, and Detroit coal ashes. These tests were reported monthly by Mr. H. E. Simpson, and mimeographed copies have been distributed to the members of the Committee. The Institute is supporting this phase of the work. Similar tests have been made by another method at the University of Illinois by Prof. R. K. Hursh, and mimeographed copies of his reports also have been sent to the members of the committee.

Elevator Safeties. M. H. Christopherson, Chairman. Tests on undercar safeties have occupied the time of the Committee's research associates at the Bureau of Standards during the year. Special test apparatus, installed in the test hoistway, was further refined during use.

The bi-monthly meetings of this Committee were continued for the purpose of reviewing the test data and preparing recommendations for use in the revision of the Safety Code for Elevators.

In July, 1931, the Committee sponsored a conference of wire rope manufacturers and users to discuss the possibility of establishing standards for inspection and condemnation of ropes in service. The program of the A.S.M.E. Wire Rope Research Committee was adopted as a method of procedure.

Worm Gears. Earle Buckingham, Chairman. Present industrial conditions have materially slowed down the progress of much of this Committee's program. Tests and other work are now being carried on in three or four plants, but the test data available is not yet sufficient to justify any further report at this time.

Welding of Unfired Pressure Vessels. E. H. Ewertz, Chairman. (Joint Committee with the American Welding Society.) A report of tests on a certain type of light-gage welded tank at Lehigh University has been made. The results obtained have been incorporated in the A.S.M.E. Boiler Code. The Committee is now considering the desirability of disbanding, as its work appears to have been completed.

Saws and Knives. A. S. Kurkjian, Chairman. Owing to the lack of financial support from the woodworking industries and manufacturers of saws and knives, this Committee has been inactive during the year.

In March, 1930, Engineering Foundation made a grant of $1000 toward the Committee's proposed experimental program, but because of the Committee's inactivity, $500 yet due on the grant was transferred to the Lubrication Committee to help meet its current research expenses.

Existing Supplies of Hardwoods. Additional sample logs of 40 different tropical species were received in New York from Central America, British Guiana, Colombia, Venezuela, and Panama. They were cut into test blanks by two importing concerns and shipped to the University of Michigan for tests.

A representative of the Tropical Plant Research Foundation, with the aid of the Pack Forest Trust and the A.S.M.E., made a personal canvass of principal wood-using and importing concerns in the United States in an effort to interest them in contributing to an investigation of the abundance and qualities of the general utility woods of the northern portion of the American tropics. He reports no success because of existing business conditions.

Strength of Vessels Under External Pressure. W. D. Halsey, Chairman. The Committee completed its survey of foreign and domestic design practice and performance records on jacketed vessels, and compiled it into useful form. At the December, 1930, meeting of the Committee, Mr. D. B. Wesstrom, member of the Committee, presented an analysis of this data in the form of tables and comparative curves which indicated that a large amount of experimental work needs to be done to verify existing formulas. Commander Saunders, member, also reported on extensive tests that have been carried on at the Model Basin, Navy Yard, Washington, D. C., on cylindrical structures subjected to collapse, and from which a new formula has been developed. He later discussed this work in a paper before the Society's Hartford Meeting, June, 1931. Mr. T. M. Jasper, member, reported at the same meeting on an investigation of the collapsing strength of steel tubes.

Absorption of Radiant Heat. W. J. Wohlenberg, Chairman. The Committee is continuing to collect and analyze the meager data available from the power industry on the absorption of radiant heat in installed furnaces.

Velocity Measurement of Fluid Flow. W. F. Durand, Chairman. The apparatus described in a previous report which required two identical sound-detecting devices suffered from the disadvantages of producing troublesome reflected sound waves. Professor Hartig has accordingly invented an improved apparatus which has the

inherent property of suppressing waves which ordinarily would give rise to disturbing reflections. A preliminary form of this new apparatus was set up and tested with moving air during the months of July and August, 1931, with encouraging results. The preliminary test suggested refinements and improvements which are now being incorporated in a more suitable design which is adapted for measuring the velocity of gases and liquids. It is planned to test the new apparatus by measuring the velocity of water, in connection with which adequate means for checking the magnitude of the velocity are available in the University of Minnesota Experimental Laboratory, where the work is in progress.

Measures of Management. W. E. Freeland, Chairman. The Committee conducted a conference at the Society's June Meeting in Hartford on the possibility of establishing formulas for the selection and replacement of manufacturing equipment. Some fifty manufacturing executives attended and brought out in the discussion the many practical elements that must be considered in developing such formulas.

The studies on this phase of the Committee's program are being carried on at the Massachusetts Institute of Technology, under the joint sponsorship of this Committee and of a similar committee of the Materials Handling Division. A report, "Economic Life of Equipment," by H. O. Vorlander and F. E. Raymond, will be presented at the December, 1931, Annual Meeting.

Diesel Fuel Oil Specifications. L. H. Morrison, Chairman. The Committee has not made much progress in formulating specifications or in research work during the year, due to reorganization and the entrance of allied technical organizations into the project. The formulation of specifications is to be handled by a Sectional Committee organized under the procedure of the American Standards Association under the sponsorship of the American Society for Testing Materials but based on data to be supplied by the A.S.M.E. Special Research Committee on Diesel Fuel Oil Specifications. A joint committee has been organized with the Society of Automotive Engineers to make a study of combustion in a Diesel engine cylinder. Efforts are now being made to raise funds from industry for this research. The A.S.M.E. Committee has in addition two subcommittees, one studying the physical and chemical properties of Diesel fuels in the laboratories of the larger oil companies in an attempt to discover the characteristics of motor fuel unsatisfactory for engine operation, and the other carrying out field tests in the shops of engine manufacturers in an effort to discover the effect of viscosity and Conradson carbon on the operation of Diesel engines.

Wire Rope. W. H. Fulweiler, Chairman. The Committee believes that a definite relation can be established between the number of broken wires and the wear of a wire rope and its remaining useful life. To test this opinion approximately 500 copies of the Committee's program and data sheets have been distributed to persons believed to be interested in collecting data on ropes in service and in sending samples from discarded ropes to the National Bureau of Standards, Engineering Mechanics Section, for testing. Arrangements have been completed with the Bureau of Standards for testing the samples and correlating the results of the tests with the collected data. Engineering Foundation is financing this phase of the investigation. In July, the Committee participated in a conference with wire rope manufacturers and users called by the Sectional Committee on the Safety Code for Elevators. The purpose of this conference was to discuss the possibility of framing rules for inspection and condemnation of ropes in service on elevators at the present time. Discussion revealed that a great deal of technical information is needed on wire rope life in service before such rules can be established. The program of the Wire Rope Committee was adopted as a method of procedure in obtaining such data.

Airplane Vibration With Special Reference to Instruments. Alexander Klemin, Chairman. The Committee has been inactive since the presentation of its report entitled "Airplane Instrument Vibration" at the December, 1930, Annual Meeting.

Heavy Duty Anti-Friction Bearings. W. Trinks, Chairman. Several concerns have cooperated with the Committee in the conduct of extensive tests on rolling mills. Three reports have been distributed during the year, in mimeographed and blueprinted form, to the members of the Committee and to contributors: these were (1) forces in the cold rolling of non-ferrous metals, (2) an analysis of German data on the forces which occur in the hot rolling of mild steel, and (3) analyses of data on roll neck forces which have been obtained in enormous quantities from the 35-in., 28-in., and 22-in. mills of the Timken Steel and Tube Company in hot rolling alloy steels.

The Committee held two meetings during the year to discuss the program and the progress made. Arrangements have been completed for a joint session with the Iron and Steel Division at the 1931 Annual Meeting at which several papers resulting from the Committee's activity will be presented.

Removal of Ash as Molten Slag From Powdered-Coal Furnaces. P. B. Rice, Chairman. Experimental investigations, under the auspices of this Committee at the Bureau of Mines, on the addition of fluxes as a means of removing ash as molten slag from powdered-fuel furnaces, were completed during the year, and a report will be presented at the December, 1931, Annual Meeting of the Society. A study is now being made of the selective separation of ash in slag furnaces. Constructors, manufacturers, and operators of power plants and power-plant equipment are financing the Committee's program.

Automatic Oil Pipe Line Pumping Stations. W. G. Heltzel, Chairman. The Committee's experimental station was completed in time for demonstration during the seventh International Petroleum Exposition in Tulsa, Okla., October, 1930. As a result of this investigation one of the more prominent oil distributing companies has during the year built six similar stations into its system.

The Committee has recently completed a survey of the functioning of these stations from which data will be used to redesign and rebuild the experimental station along greatly improved lines.

Methods and Apparatus for Noise Measurement. W. B. White, Chairman. The Committee is confining itself to the development of an objective scale for measurement and apparatus for the determination of sound values in a manner universally acceptable. A résumé of the Committee's first report appeared in the May, 1931, issue of *Mechanical Engineering.*

This committee participated with other interested organizations in the symposium on sound measurement conducted by the North Eastern District of the American Institute of Electrical Engineers at Rochester, N. Y., April 29–May 2, 1931.

The project has developed steadily and the general facts and ideas accumulated have been circulated to the committee members. In the spring the Committee expects to submit a report which will contain a tentative, well-considered formula.

Rotary Drilling of Oil Wells. D. L. Trax, Chairman. Organized originally in January, 1930, to investigate the operating efficiencies of steam equipment used in the rotary drilling of oil wells. The Committee's scope was later enlarged to include a study of electrical, gas engine, and Diesel-engine-driven equipment designed for the same purpose.

The study of steam drilling was made first, and one of the oil companies in the Oklahoma field made it possible for the Committee to conduct its tests during the drilling of a new well. Special metering and other apparatus necessary for the investigation were contributed by local concerns, and the tests were all directed by Prof. W. H. Carson, Head of the Department of Mechanical Engineering of the University of Oklahoma. The work was completed during the summer months and an extensive report has been prepared for publication.

Critical Pressure Steam Boiler. A. A. Potter, Chairman. This new committee was organized in August, 1931, to advise with the Engineering Staff of Purdue University in a study of the action of steam in a boiler at and above the critical pressures. Tests have been conducted on a 3500 lb. experimental steam generator and auxiliaries recently installed in the Mechanical Engineering Laboratory of the University with the cooperation of several manufacturers and users of steam-generating equipment. This investigation is expected to supplement in a practical way the program of the Special Research Committee on Thermal Properties of Steam. A paper by members of the Committee will be presented at the 1931 Annual Meeting of the Society. This will describe results of preliminary investigations including automatic control, pressure-temperature relations, and heat transfer.

Physical Constants of Refrigerants. (Joint sponsorship with American Society of Refrigerating Engineers. No personnel yet appointed.) Owing to the depressed condition of business, efforts to collect funds from industry to support a proposed research at the Bureau of Standards on the determination of the physical constants of certain refrigerants were not successful. The project is therefore being held in abeyance till conditions improve.

Respectfully submitted,

W. Reuben Webster, *Chairman*
Walter H. Fulweiler
Alex D. Bailey
Andrey A. Potter
F. C. Biggert, Jr.

STANDARDIZATION COMMITTEE

The A.S.M.E. Standardization Committee presents the following as its report for the year October 1, 1930, to October 1, 1931.

Organization

During the past year the Society accepted one sole sponsorship, that for the Standardization of Specifications for Leather Belting, January, 1931, and one joint sponsorship with the American Foundrymen's Association for the Standardization of Foundry Equipment, February, 1931. To date the Society has accepted sponsorship or joint sponsorship for a total of 29 sectional committees under the procedure of the American Standards Association. These sectional committees have subdivided themselves into 238 subcommittees and subgroups in order that the work assigned to them may be carried forward more promptly and effectively. The total number of members of these committees is now 1090, of which 397 are members of the A.S.M.E.

Organization meetings of the following three Sectional Committees were held: Pressure and Vacuum Gages in December, 1930; Specifications for Leather Belting in May, 1931; and Foundry Equipment in May, 1931. The reorganization meeting of the Sectional Committee on Plain Limit Gages for General Engineering Work was held in December, 1930, at which time it was decided to change the name to Allowances and Tolerances for Cylindrical Parts and Limit Gages. In all, 81 standards committee meetings were held during this year.

Standards Approved

Four standards were completed under the A.S.A. procedure and published in pamphlet form this past year. These are the standards for 25 Lb. Cast Iron Flanges and Flanged Fittings; Track Bolts; Woodruff Keys, Keyslots, and Cutters; and Symbols for Heat and Thermodynamics.

Publicity

During the year 33 pages of text pertaining to the Society's work in standardization were published in *Mechanical Engineering*. Part of this material was published in the Engineering and Industrial Standardization section of *Mechanical Engineering*, and the remainder consisted of the reproductions of preliminary proposals issued from time to time by the committees. Thirty-two hundred copies of tentative draft standards in printer's proof form were distributed to consumer and producer interests and to the technical press during the year.

Mechanical Standards Advisory Council

The Mechanical Standards Advisory Council, organized in December, 1928, to advise this industry and the American Standards Association on questions relative to the initiation and development of dimensional standards and material specifications of special interest to these groups, held a meeting in December, 1930. At this meeting it was voted to increase the personnel of the Executive Committee from seven to nine members; this vote included the recommendation that three members be elected each year for a term of three years.

Since this meeting the new executive committee has been elected by letter ballot and now consists of the representatives of the American Gas Association; American Society for Testing Materials; American Society of Mechanical Engineers; American Institute of Bolt, Nut and Rivet Manufacturers; Heating and Piping Contractors National Association; Manufacturers' Standardization Society of the Valve and Fittings Industry; National Electric Light Association; National Machine Tool Builders Association; and the Society of Automotive Engineers. The Council now consists of 24 member organizations.

Sectional Committee and Subcommittee Reports

Shafting. C. M. Chapman, Chairman. In January, 1931, favorable reactions were received from the committee members on the proposed extension of the shafting diameters and flat key series for shafts larger than 6 in.

The four existing standards, namely, Cold Finished Shafting with an addition covering recommended diameters for forged shafting larger than 6 in., Square and Flat Stock Keys (1925), including the extension for large flat keys, Plain Taper Stock Keys (1927), and Gib-Head Taper Stock Keys (1927) were then tentatively combined under a single cover with appropriate introductory notes and title.

During the review of the combined standard by the committee members certain questions were raised in connection with the larger sizes of shafting and keys, and in order to obtain authoritive information on these points a questionnaire was distributed to the larger manufacturers and users of this material. The answers to this questionnaire and their bearing on the proposed extension to the shaft and key sizes will be discussed at the next meeting of the Sectional Committee, scheduled for the third week in October.

Subcommittee on Woodruff Keys. L. C. Morrow, Chairman. The American Standard for Woodruff Keys, Keyslots, and Cutters was approved by the American Standards Association in December, 1930, and is now available in pamphlet form.

Allowances and Tolerances for Cylindrical Parts and Limit Gages. E. J. Kearney, Chairman. The reorganization meeting of the Sectional Committee on Plain Limit Gages for General Engineering Work was held in December, 1930, letters having been sent to 62 interested organizations requesting them to appoint representatives. The appointments made up to the time of the meeting were discussed and several persons were added as "members at large," bringing the personnel to a total of 43 members. Mr. C. E. Rundorff, of the Buick Motor Company, Flint, Mich., was elected secretary.

After reviewing the work of the original Committee and the extent to which the original standard had been accepted by industry, several alternative tolerance systems were discussed.

The plan and scope of the Committee's work were analyzed and it was recommended that certain changes be made in the wording of the "Scope." It was also recommended that the Committee's name be changed to "Sectional Committee on the Standardization of Allowances and Tolerances for Cylindrical Parts and Limit Gages."

The appointment of subcommittees to facilitate handling the various phases of the work was left to the discretion of the chairman, who has been in touch with the members regarding a plan for the activities of the Committee, and it is expected that another meeting will be held before the end of the calendar year.

Ball and Roller Bearings. F. W. Gurney, Chairman. The American Standard on Ball and Roller Bearings of the Single Row Type and Recommended Practice for the Wide Type was completed by this Sectional Committee and approved by the American Standards Association in April, 1930. The Standardization of Metric Thrust and Roller Bearings is being contemplated by the Committee as its next activity.

Gears. B. F. Waterman, Chairman. While no tangible results in the form of American Standards have been produced this year by the Sectional Committee on the Standardization of Gears, several of its subcommittees have made considerable progress toward this end.

Subcommittee on Nomenclature. E. W. Miller, Chairman. A decision was reached at the September, 1930, meeting of the A.G.M.A. Committee on Nomenclature that the series of multiple letter symbols be designated as "abbreviations" and that a series of single letter symbols be developed for inclusion in the proposed recommended practice of the A.G.M.A. covering symbols, abbreviations, and definitions. During the year the A.G.M.A. Committee and this Subcommittee prepared a proposal based on this idea. Copies of the latter were generally distributed for criticism and comment. To coordinate its work with the recommendations of the Sectional Committee on Scientific and Engineering Symbols and Abbreviations three members of the latter Committee are to be appointed to confer with the Subcommittee on Nomenclature.

Subcommittee on Spur Gear Tooth Form. H. J. Eberhardt, Chairman. The letter ballot of the Sectional Committee on the Proposed American Standard for the Tooth Form of the 14½ Deg. and 20 Deg. Full Depth Involute System was completed during August. Chairman Eberhardt is now reviewing the comments received with these ballots, after which it will be submitted to the A.G.M.A. and A.S.M.E., the sponsor organizations, for approval. This standard when finally approved by the A.S.A. will be combined and printed in one pamphlet with the first standard prepared by the Subcommittee, covering the tooth form of the stub tooth systems.

Subcommittee on Helical Gears. A. A. Ross, Chairman. During the past year agreement on the fundamentals of its report on herringbone gears, with the exception of tooth load formulas, was reached by the Subcommittee. The subject of tooth load formulas is receiving careful consideration but it will be necessary for the Subcommittee to await the completion of certain tests at the Massachusetts Institute of Technology before definite recommendations on this part of the subject can be made. One informal meeting of several members of the Committee was held in Buffalo at the time of the 1931 meeting of the A.G.M.A.

Subcommittee on Inspection of Gears. G. L. Markland, Chairman. The Subcommittee's present proposal is in printer's proof form, dated March, 1929. It was based largely on the recommended practice of the A.G.M.A. Recently the A.G.M.A. Committee on this subject has made a careful review of this material

and in turn proposed a redraft at the May, 1931, meeting of the Association. This revised proposal will be given due consideration by the Subcommittee on Inspection.

Subcommittee on Materials. T. D. Lynch, Chairman. In April, 1931, Mr. Chester B. Hamilton, Chairman of the A.G.M.A. Committee on Gear Materials, advised Chairman Lynch that his Committee had approved, with a few minor changes, the proposed American Standard for Gear Materials and Blanks developed by this Subcommittee. Chairman Lynch is, accordingly, drafting a finally revised proposal.

Pipe Flanges and Fittings. C. P. Bliss, Chairman. The proposed Standard for 25 Lb. Cast Iron Pipe Flanges and Flanged Fittings approved in 1930 by this Sectional Committee and the Sponsors was designated by the A.S.A. as an American Standard in April, 1931. In July, 1931, the proposed standard for 800 Lb. Hydraulic Cast Iron Pipe Flanges and Flanged Fittings was submitted to the A.S.A. for approval and designation as an American Standard. The group of this Sectional Committee's published standards are: 250, 400, 600, 900, and 1350 Lb. Steel Pipe Flanges and Flanged Fittings; 125 and 250 Lb. Cast Iron Screwed Fittings; 150 Lb. Malleable Iron Screwed Fittings; 125 and 250 Lb. Cast Iron Long Turn Sprinkler Fittings; 25 Lb. Cast Iron Pipe Flanges and Flanged Fittings; 125 Lb. Cast Iron Pipe Flanges and Flanged Fittings; 250 Lb. Cast Iron Pipe Flanges and Flanged Fittings. In accordance with action taken at the meeting of the Sectional Committee on December 5, 1930, an additional Subcommittee, No. 9 on Port Openings, was appointed. The Chairman reports progress on the various subcommittees as follows:

Subcommittee No. 1 on Cast Iron Flanges and Flanged Fittings. A. M. Houser, Chairman. The proposed American Standard for 800-Lb. Hydraulic Cast Iron Pipe Flanges and Flanged Fittings, approved last year by the Sectional Committee, was submitted in July, 1931, to the American Standards Association. This action was taken after final agreement had been reached on the paragraphs pertaining to "Marking" and "Materials." These paragraphs were revised at the Sectional Committee meeting held in December, 1930, to meet the wishes of the Manufacturers Standardization Society of the Valve and Fittings Industry.

The standard for 25 Lb. Cast Iron Pipe Flanges and Flanged Fittings prepared by this Subcommittee and submitted to the American Standards Association in September, 1930, was approved and designated as an American Tentative Standard in April, 1931.

A first draft of a proposed American Standard for Ammonia Pipe Flanges and Flanged Fittings was approved as a recommended practice by the Refrigerating Machinery Association at its spring meeting, in May, 1931. Since then it has been re-edited and will be submitted as a preliminary draft to the Subcommittee upon receipt of approval of certain editorial changes from the Refrigerating Machinery Association.

Subcommittee No. 2 on Screwed Fittings. S. G. Flagg, Jr., Chairman. The proposed standard for Pipe Plugs of Cast Iron, Malleable Iron, Cast Steel and Forged Steel distributed in October, 1930, to industry for criticism and comment was discussed at the December, 1930, meeting of the Sectional Committee. At that time it was referred back to Subcommittee No. 2 for further consideration in the light of the comments received. It is expected that the Subcommittee will meet for this purpose at an early date.

Subcommittee No. 3 on Steel Flanges and Flanged Fittings. C. P. Bliss, Chairman. During the year this Subcommittee held two meetings, one in October, 1930, and the second in April, 1931. Difficulty was experienced in setting the "pressure-temperature" ratings for the 150 lb. standard, with the result that action was postponed pending further investigation by the Manufacturers Standardization Society of the Valve and Fittings Industry and the Committee members. The 250 lb. standard was rerated to 300 lb., with the metal thickness of the fittings increased where necessary, all other dimensions remaining unchanged. The 1350 lb. standard was rerated to 1500 lb., with increased metal thickness and, in sizes over 4 in., revised flange thicknesses. Before final action is taken the revised proofs are being submitted to the A.P.I. and N.E.L.A., and their comments will be available in the near future.

Subcommittee No. 5 on Face-to-Face Dimensions of Ferrous Flanged Valves. F. H. Morehead, Temporary Chairman. No actual progress in the work of this subcommittee is reported this year. In January a further request for the delimiting of the scope of this Subcommittee's activities was expressed by the Manufacturers Standardization Society of the Valve and Fittings Industry. The scope now covers the standardization of face-to-face dimensions for certain types of cast iron valves in a range of sizes for pressures of 125 and 250 lb. and for certain steel valves for 150 and 300 lb. pressure.

Subcommittee No. 6 Malleable Iron or Steel Brass Seat Unions. C. P. Bliss, Temporary Chairman. The work of this Subcommittee during the past year has been limited to the consideration of the tolerances and allowances proposed by the A.R.A. Subcommittee on Locomotive Design and Construction. This question is still in the hands of a manufacturers' subgroup.

Subcommittee No. 8 on Marking of Pipe Fittings. W. S. Morrison, Temporary Chairman. Although a good response was received to the questionnaire on "Marking" sent out by this Subcommittee late in 1929, action has been postponed pending the results of the investigation of this subject being made by the Manufacturers Standardization Society of the Valve and Fittings Industry, which should be available shortly.

Subcommittee No. 9 on Port Openings. W. W. Hubbard, Chairman. This Subcommittee of six members was appointed in April, 1931, in accordance with action of the Sectional Committee at its meeting in December, 1930. Although it has not as yet held its first meeting, some progress toward definition of its scope of activity has been made through correspondence.

Bolt, Nut, and Rivet Proportions. A. E. Norton, Chairman. The Sectional Committee on the Standardization of Bolt, Nut, and Rivet Proportions through the activities of nine subcommittees has developed and approved seven standards which have received recognition as American Standards by the A.S.A. These are the standards for Small Rivets; Tinners', Coopers', and Belt Rivets; Wrench Head Bolts and Nuts and Wrench Openings; Slotted Head Proportions; Track Bolts and Nuts; Round Unslotted Head Bolts (Carriage, Step and Machine Bolts); and Plow Bolts.

Subcommittee No. 1 on Large and Small Rivets. J. E. Kiernan, Chairman. In March, 1931, the Chairman released a revision of the proposed American Standard for Large Rivets based on the criticisms received from the distribution of the draft dated March, 1929, to the members of the Subcommittee. The printer's type was accordingly corrected and revised page proofs were sent to the members of the Subcommittee in June, 1931, for approval, prior to submission to the Sectional Committee for approval by letter ballot. The Chairman expects to release this final draft shortly after October 1.

Subcommittee No. 2 on Wrench Head Bolts and Nuts. H. A. Spanagel, Chairman. The proposed revision of the American Tentative Standard, originally approved by the A.S.A. in February, 1927, has been completed during the year. Preliminary copies of the revised draft were distributed in May, 1931, to the members of this Subcommittee for their consideration and approval. With a few exceptions the members have indicated their approval, and this subject will be discussed at a meeting of the Subcommittee which is to be held at an early date. A joint subgroup, consisting of three members appointed by the Sectional Committee on Pipe Flanges and Flanged Fittings and three appointed by this Subcommittee, are studying the special requirements for bolt heads and nuts for use in flanged pipe connections. The personnel of this Committee includes Messrs. F. W. Martin, A. M. Houser, H. D. Summers, O. B. Zimmerman, J. H. Edmonds, E. Ward. No report has been received as yet from this Subgroup.

Subcommittee No. 9 on Socket Head Cap and Set Screws. H. Koester, Chairman. This Subcommittee held meetings in December, 1930, and April, 1931, to complete the preparation of its proposed Standard for Socket Head Cap and Set Screws, and since the April meeting several minor revisions have been made by correspondence. In September, 1931, this proposal was formally released by the Subcommittee and will be set in type at an early date for distribution to industry for criticism and comment.

Identification of Piping Systems. A. S. Hebble, Chairman. The present American Recommended Practice, "Scheme for Identification of Piping Systems," was developed by this Committee and approved by the American Standards Association in November, 1928. Since the publication of this "Recommended Practice" a need has been indicated for a detailed system of identification for powerhouse piping. The suggestion that such a system be developed was placed before the members of the Committee in March, 1931, for their consideration.

Small Tools and Machine Tool Elements. C. W. Spicer, Chairman. The Sectional Committee on the Standardization of Small Tools and Machine Tool Elements met in December, 1930, to review and discuss the problems of the 15 technical committees which are at work on the projects before the Sectional Committee. The standards of this group which have been approved by the A.S.A. and published by the A.S.M.E. are: T-Slots, Their Bolts, Nuts, Tongues, and Cutters; Tool Holder Shanks and Tool Post Openings; Milling Cutters; and Cut and Ground Thread Taps.

Technical Committee on T-Slots. E. Oberg, Chairman. The Cincinnati Milling Machine Company has submitted to the Tech-

nical Committee a suggestion that the depth of engagement of the present standard tongue be increased. Blueprints showing the maximum and minimum conditions and copies of the correspondence were sent to the members of the Committee. The Chairman now plans to hold a meeting in December for the purpose of discussing this question.

Technical Committee on Machine Tapers. E. F. DuBrul, Chairman. At the meeting held in October, 1930, it was decided that a layout for gages, including necessary drawings and dimensions for tapers based on present practice, be developed, and that consideration be given to the proposed tolerances on the large dimension shanks and holders. In April, 1931, the American Standards Association transmitted to the Committee, through its Chairman, a proposal from the International Standards Association concerning the advisability of postponing the development of an American Standard until an international standard had been evolved. The replies received reflected the opinion that it was difficult for European engineers to understand the vast expense which would be involved in a change in this country to the metric system of measurement. This made it impossible for the American Committee to consider any standardization on a metric basis.

Technical Committee on Spindle Noses and Collets for Machine Tools. E. F. DuBrul, Temporary Chairman. A revised draft of the proposed American Standard for Lathe Spindle Noses, dated March, 1931, was distributed by the Committee in April, 1931, for criticism and comment. This revision represents the work of the Subgroup on Correlation of Counter Proposals for Spindle Noses. A number of meetings of the Subgroup were held during the past twelve months to prepare this revised draft and to discuss the comments received. At the present time the testing of the new type of spindle nose under commercial conditions is in progress, and the Committee expects to report a definite recommendation within the next few months.

This activity has been correlated with the work of the Technical Committee on Chucks and Chuck Jaws in so far as it relates to the standardization of dimensions of the contact surfaces of the chuck and the spindle end.

Technical Committee on Designations and Working Ranges of Machine Tools. E. F. DuBrul, Temporary Chairman. The Committee held a meeting in New York in October, 1930, and decided first to direct its activities toward the standardization of the designations and working ranges of planers, engine lathes, cylindrical grinders, milling machines, and radial drills. The Committee's plans call for a canvass of the manufacturers of these machines for data on the designations they are now using and the working ranges of the machines of these types which they produce.

Technical Committee on Drill Bushings. C. J. Oxford, Chairman. In accordance with the action taken at the June, 1930, meeting of the Committee the recommendations contained in its Proposal "C" on Twist Drill Sizes and Lengths, distributed to industry in February, 1930, have been put into actual practice during the year by several large users of the product. Further action by the Committee on the proposed standard has been postponed, pending the results of this phase of the work which is still in progress. The criticisms and comments received from the distribution of Proposal "C" are being reviewed by the members of the Committee. Chairman Oxford states that in all probability the Committee will meet during the 1931 Annual Meeting of the A.S.M.E.

Technical Committee on Drill Jig Bushings. C. E. Rundorff, Chairman. Through correspondence during the year the Committee has reached a unanimous agreement on the dimensions and tolerances for headless and head press fit bushings, liner bushings, knurled head slip bushings, and nomenclature contained in its preliminary proposal, dated June, 1930. However, consideration is now being given to a suggestion for a change in the proposed hole size limits. As soon as this question is settled the proposed standard will be released for duplication and for distribution to a list of manufacturers, users, and interested individuals for criticism and comment.

Technical Committee on Punch and Die Holders. S. Diamant, Chairman. The Committee met in December, 1930, and in May, 1931. Reports on the two questionnaires which had been distributed by the Committee were made and a subgroup was appointed to study carefully the replies received and to draft a proposal based on them. The subgroup held one meeting in Chicago in January, 1931, and it is expected that a preliminary standard will be in form for distribution within a short time.

Technical Committee on Circular Forming Tools and Holders. W. C. Mueller, Chairman. The organization meeting of this Committee took place in March, 1931. At this meeting the Committee decided to prepare and distribute two questionnaires, one to cover the proportions of circular forming tools and the other to cover dovetailed circular forming tool blanks. These questionnaires were developed and submitted to the Committee in July, 1931, for review and comment prior to general distribution to the large users of circular forming tools and to the manufacturers of the machine tools in which circular forming tools are used.

Technical Committee on Chucks and Chuck Jaws. J. E. Lovely, Chairman. During the year this Committee held two meetings, the first in October, 1930, and the second in June, 1931. In March, 1931, two proposed standards, one on Rotating Air Cylinders and Adapters and the other on Chucks and Chuck Jaws, were distributed in proof form to industry for criticism and comment. A careful review of the comments was made and the proposed Standard for Rotating Air Cylinders and Adapters was approved, with minor revisions, for submission to the Sectional Committee. In September, 1931, the changes authorized were formally released by the Chairman for incorporation in a revised draft of the proposal. It was deemed advisable, however, to investigate further certain elements of the proposal for Chucks and Chuck Jaws, and a report of these studies will be made at the next meeting of this Committee.

Technical Committee on Cut and Ground Thread Taps. C. M. Pond, Chairman. Good progress has been made by this Committee during the past twelve months in the development of standards for special types of taps, such as ground thread pulley taps, cut and ground thread bent shank tapper taps, cut thread taper pipe taps, etc. These new standards when completed and approved will be combined with the present American Standard for Cut and Ground Thread Taps approved and published in April, 1930. One meeting of the Committee was held in December, 1930, and another has been scheduled for October, 1931. It is expected that following the coming meeting the Committee's proposal will be released for distribution to industry.

Technical Committee on Splines and Splined Shafts. C. W. Spicer, Chairman. In November, 1930, the Committee held a meeting in Detroit. Prior to the meeting copies of a number of manufacturers' data sheets on this subject were sent to the members for consideration. A review of this material and the discussion at the meeting indicated considerable divergence in present practices. Accordingly two subgroups were appointed to study the subject and to draft preliminary proposals; Subgroup No. 1 to cover splines as applied to machine tools and Subgroup No. 2 to cover splines as applied to automotive uses.

Technical Committee on Electric Welding Dies and Electrode Holders. J. A. Weiger, Chairman. This Committee held one meeting this year, in April, 1931. The attendance at the meeting was small and consequently little progress was made in the development of its preliminary proposal. The Chairman endeavored to hold a meeting during the Annual Meeting of the American Welding Society at Boston in September, 1931, but the time and place were not convenient to the majority of the members.

Technical Committee on Milling Machine Tables. G. A. Bouvier, Chairman. At its meeting in December, 1930, the Committee reached a tentative agreement on table widths for eight sizes from 3 in. up to and including 21 in. Agreement was reached also on the size and width of T-slots for these table widths and the slot spacing. Blueprints showing the proposed standard cross-sections of milling machine tables were distributed to the members of the Committee in March, 1931, and it is now actively at work on the further development of this proposed American Standard.

Scientific and Engineering Symbols and Abbreviations. J. F. Meyer, Chairman. During the year one additional standard was added to the list of standards previously completed and published by the Committee. Two more were passed through all but the final stages of the approval procedure. This year's accomplishments, therefore, practically complete the work originally assigned to this Sectional Committee. The eight standards so far approved by the A.S.A. and published are: Symbols for Hydraulics; Symbols for Heat and Thermodynamics; Symbols for Photometry and Illumination; Aeronautical Symbols; Mathematical Symbols; Letter Symbols for Electrical Quantities; Navigational and Topographical Symbols; Graphical Symbols for Telephone and Telegraph Use.

Subcommittee on Symbols for Mechanics, Structural Engineering and Testing Materials. J. T. Faig, Chairman. The Subcommittee completed its proposed list of symbols in October, 1930. Following approval by the Sectional Committee, the proposed standard was submitted to the five sponsor bodies, which are now voting on it.

Subcommittee on Symbols for Heat and Thermodynamics. S. A. Moss, Chairman. The American Tentative Standard, "Symbols for Heat and Thermodynamics," was approved and published in February, 1931.

Subcommittee on Abbreviations of Engineering and Scientific Terms. G. A. Stetson, Chairman. This Subcommittee's proposal is now with the sponsor organizations for approval. Three of the

five have given their approval of this proposal and final action by the other two is expected in the near future.

Plain and Lock Washers. C. W. Squier, Chairman. The Sectional Committee on the Standardization of Plain and Lock Washers has given some attention this year to the building up of its personnel. Since this was weak on the producer side the manufacturers of this product were requested to nominate persons employed in this industry who might be appointed to the Committee as "Members at Large." Satisfactory response was received and the resulting list of nominations will be acted upon at a meeting to be held in October. As soon as this personnel has been completed by the Sectional Committee it will be submitted to the American Standards Association for its approval.

Subcommittee on Lock Washers. C. H. Loutrel, Chairman. The Subcommittee on Lock Washers met in December, 1930, and again in April, 1931, to discuss tentative proposals. In September, 1931, another tentative proposal was distributed to the members of the Subcommittee for consideration prior to its next meeting, which has been scheduled for October. In developing these proposals the Subcommittee has confined its activity entirely to lock washers to fit the present American Standards for Wrench Head Bolts and Nuts (B18b-1927) and Slotted Head Proportions (B18c-1930).

Machine Pins. M. E. Steczynski, Chairman. The Sectional Committee on Machine Pins distributed a preliminary draft of its proposed standard to industry for criticism and comment in January, 1931. A large number of constructive comments were received. These are now in the hands of the Committee for consideration and incorporation in its revised proposal. As soon as this work has been completed a meeting of the Sectional Committee will be held for a thorough discussion of this entire subject.

Code for Pressure Piping. E. B. Ricketts, Chairman. The Sectional Committee on a Code for Pressure Piping met in December, 1930, and May, 1931, to discuss the several sections of the code proposed by its subcommittees. Another meeting is scheduled for October.

Subcommittee on Power Piping. John Lawrence, Chairman. At the meeting of this Subcommittee held in April, 1931, the revised proposal for Section 2, Power Piping Systems, which had been distributed to the members of the Committee earlier in the month, was discussed. The Subcommittee has decided to delay the final submission of Section 2 of the Code until a decision has been reached by the Manufacturers Standardization Society of the Valve and Fittings Industry on standard shell test pressures and by the Sectional Committee on the unification of the pipe thickness formulas used in the several sections.

Subcommittee on Gas and Air Piping. Alfred Iddles, Chairman. This Subcommittee reported at the May, 1931, meeting of the Sectional Committee that objections had been raised by the American Gas Association to certain paragraphs of its tentative proposal on Section 4, and that the A.G.A. had formulated a redraft of these paragraphs which exp ssed its views on the subject.

Subcommittee on Refrigerating Piping. A. H. Baer, Chairman. The first meeting of this Subcommittee was held in December, 1930, at which a preliminary outline of Section 5 distributed to the members in November was discussed, changed, and extended. It was pointed out that there are few if any precedents in the regulation of refrigerating piping. The Chairman submitted a tentative proposal for Section 5 to the members in April, 1931, for criticism and comment. This first rough draft has recognized the several requirements of the many different kinds of refrigerants, most of which make necessary differences in materials, joints, etc. However, the Committee plans to cover only the refrigerants in common use. It is expected that this proposal will be in tentative shape for distribution to the members of the Sectional Committee at an early date.

Subcommittee on Oil Piping. A. D. Sanderson, Chairman. This subcommittee has developed three tentative drafts of this proposal, dated January, March, and September, 1931. These drafts have been discussed by the members of the Subcommittee and at the meeting of the Sectional Committee held in May, 1931. The September draft will be discussed at the meeting of the Subcommittee to be held in October and reported at the Sectional Committee meeting the following day.

Subcommittee on Piping Materials and Identification. F. H. Morehead, Chairman. The meeting of this Subcommittee in October, 1930, dealt principally with schemes for marking and identification of pipe and fittings and with the plans of the Manufacturers Standardization Society of the Valve and Fittings Industry to present a recommendation on this subject. In September, 1931, the Chairman submitted a revised list of material specifications to the members for criticism. During the year the Subcommittee has also been conducting a study of the thermal expansion of pipe material.

Subcommittee on Fabrication Details. C. G. Spencer, Chairman. The five subgroups of this Subcommittee have been very active this year in developing questionnaires and draft proposals of the various sections on Hangers; Joints Other Than Welded; Pipe Bends; Power Piping; and Welding. The subgroup on Hangers, Supports and Anchors has distributed preliminary drafts of its proposal, dated January, April, June, and October, 1931, to the members of the Subcommittee for consideration. In January, 1931, the subgroup on Joints Other Than Welded distributed to the Chairmen of five Subcommittees of the Sectional Committee copies of the summary of the replies to the questionnaire which it had mailed to industry in June, 1930. Under date of August, 1931, the subgroup sent to the members of Subcommittee on Fabrication Details the subgroup's proposal, dated July, 1931. This proposal was based on the replies to a questionnaire sent out in June. The December, 1930, proposal of the subgroup on Welding was discussed at a joint meeting of the American Welding Society and the Sectional Committee held in New York in April, 1931. Copies of the discussion at this meeting were mailed to the members of the Subcommittee for their information in July, 1931. A meeting of this subgroup was held in Boston in September. This subgroup has developed a revised draft of its August proposal which will be discussed at the October meeting of the Sectional Committee.

Subcommittee on District Heating Piping. D. S. Boyden, Chairman. Two meetings of the Subcommittee on District Heating Piping were held during the year, one in December, 1930, and the other in April, 1931. This Subcommittee has prepared four drafts of its proposal during the past year. These were dated November, December, 1930; April and June, 1931. The last was distributed to the members of the Subcommittee in September for study prior to reporting at the meeting of the Sectional Committee in October.

Drawings and Drafting Room Practice. F. DeR. Furman, Chairman. During the past twelve months this Sectional Committee has not had occasion to hold a meeting. The Editing Committee made up of the Chairmen of the six Subcommittees, held an important meeting on January 2 and 3, 1931. At this meeting the progress made so far by the Subcommittees was thoroughly discussed and plans were formulated for the completion of the various sections of the Sectional Committee's report.

The Subcommittee on Specifications for Paper and Cloth developed a new series of proposed sizes in January, 1931, copies of which were sent to the members of the Subcommittee. The Subcommittee on Methods of Indicating Dimensions distributed a preliminary proposal in October, 1929. A summary of the replies are now in the hands of the Chairman of the Subcommittee, and it is expected that a tentative proposal will be ready for submission to the Sectional Committee for its consideration at its next meeting. The Subcommittee on Lettering developed a revised proposal in line with suggestions made at the January meeting of the Editing Committee, and in April, 1931, copies were mailed to the members of these two groups. The Subcommittee on Line Work distributed to industry in March and April, 1931, a questionnaire on the method of representing screw threads on drawings. The replies to this questionnaire are now in the hands of this Subcommittee for consideration.

Graphic Presentation. E. F. DuBrul, Chairman. The Sectional Committee on Graphic Presentation held no meeting during the year. Subcommittee No. 3 on Time Series Charts, No. 4 on Non-Time Series Charts, and No. 5 on Survey of Current Practice held a joint meeting in October, 1930, which resulted in the combining of the three committees into one Subcommittee on Preferred Practice in Graphic Presentation, with Mr. A. H. Richardson as Chairman. This new Subcommittee plans to divide its program of work among small subgroups.

Subcommittee on Scientific and Engineering Graphs. W. A. Shewhart, Chairman. The Subcommittee on Scientific and Engineering Graphs held an open meeting during the 1930 Annual Meeting of the A.S.M.E. Three papers were presented at this time under the following titles: (1) "Appearance Factors in Engineering Graphs;" (2) "Attention Value of Good Chart Design;" and (3) "Angle of View and Its Bearing on Layout, Proportions, Weights of Lines and Lettering of Lantern Slides." The first of these papers is to form one of a series of three monographs to be submitted by this Committee for publication during the next few months. The Subcommittee is now making plans for an open meeting to be held during the first week of December in New York, N. Y. At this time one of the subjects of discussion will be the principles of chart construction effecting the production of good lantern slides.

Transmission Chains and Sprockets. F. V. Hetzel, Chairman. This Sectional Committee on Transmission Chains and Sprockets

developed the American Standard for Roller Chains, Sprockets, and Cutters which was approved by the American Standards Association in July, 1930, and is now available in the pamphlet form, published by the Society of Automotive Engineers. The Committee now has under consideration the standardization of Silent Chains. The personnel of the Sectional Committee was approved by the A.S.A. in May, 1931.

Wire and Sheet Metal Gaging Systems. W. W. Hutchins, Temporary Chairman. While the Sectional Committee on Wire and Sheet Metal Gaging Systems has undertaken the development of standard gaging systems for (1) Flat Stocks, (2) Wires and Rods, and (3) Tubing, Piping, Casing, and Conduit, no progress has been reported during the past twelve months.

Electric Motor Frame Dimensions. W. F. Dixon, Chairman. In January, 1931, this Sectional Committee met for the purpose of clarifying the situation arising out of the request by the N.E.M.A. that the A.S.A. withhold approval of the proposed standard for mounting dimensions of general purpose motors which was submitted to the A.S.A. in April, 1930, by the A.S.M.E. and the N.E.M.A. as joint sponsors. At this meeting the N.E.M.A. proposed the adoption of a restricted scope for the Committee's activities, under which it would be willing to cooperate in the standardization of motor frame dimensions. This abridged scope was accepted tentatively by those present at the meeting subject, to a formal canvass of the Sectional Committee membership by letter ballot. The scope proposed by the N.E.M.A. consists of the following three items: (1) a series of dimensions for the height between the plane of base and the center line of shaft; (2) the spread, at right angles to the center line of the shaft, between the bolt holes, definitely co-related to each dimension in Item 1; (3) the distance, parallel with the line of the shaft, from the center line of the bolt holes next to the driving end of the motor to the shoulder of the shaft, also definitely co-related with each dimension in Item 1.

Pipe Threads. E. M. Herr, Chairman. Three Subcommittees have held meetings during the past year and the progress reported is recorded in the following paragraphs:

Subcommittee on Taper Pipe Threads. S. B. Terry, Chairman. In October, 1930, this Subcommittee met on two consecutive days and discussed in detail the proposed editorial revision of the Taper Pipe Thread section of the American Pipe Thread Standard published in 1919. A considerable proportion of the text was tentatively revised at that time and the remainder has been completed since through correspondence. Two informal conferences were also held during the year. The proposed revision of this section, in printer's proof form, is now in the hands of the committee members for consideration at the next meeting, which it is expected will be held before the end of the calendar year.

The possible consolidation of the American Standard Pipe Thread and A.P.I. Standard Line Pipe Thread has been given considerable attention, but no definite conclusion has been reached so far.

Subcommittee on Straight Pipe Threads. Alton S. Miller, Temporary Chairman. A meeting of this Subcommittee was held in October, 1930, and the character and scope of the Committee's work was discussed at length. As a result of this discussion it was decided to develop basic dimensions for gages on the basis of two pitch diameters, one for pressure joints and one for locknut threads. The development of "go" and "not go" gages for threadings not readily gaged by the present taper plug gages was also decided upon.

Subcommittee on Plumbers Threads. L. A. Cornelius, Chairman. This Subcommittee has held one meeting during the past twelve months, in December, 1930, at which the reports of its three subgroups were discussed. Two of these reports, on "threading for thin wall non-pressure tubing in sizes larger than 2 in." and "threading for 14 and 17 gage non-pressure tubing in sizes 2 in. and smaller" were accepted as complete. The third, on threading for corporation stops, was recommended for adoption, subject to certain modifications in thread sizes and the inclusion of tolerances. It is anticipated that this report in completed form will be available for distribution to the Subcommittee members at an early date.

Subcommittee on Screw Threads for Rigid Electrical Conduit. H. S. White, Temporary Chairman. While no meeting of this Subcommittee has been held during the past twelve months, a threading specification for rigid electrical conduit has been adopted recently as standard by the conduit manufacturers. This specification covers threading dimensions and tolerances for sizes $^1/_2$ in. to 6 in., inclusive, and copies are being forwarded to the Subcommittee members for their consideration.

Wrought Iron and Wrought Steel Pipe and Tubing. H. H. Morgan, Chairman. In June, 1931, a meeting of the Sectional Committee on Wrought Iron and Wrought Steel Pipe and Tubing was held in Chicago during the A.S.T.M. Convention, and a report of the progress made at a joint meeting of Subcommittee on Pipe and Tubing for Low Temperature Service and Subcommittee on Pipe and Tubing for High Temperature Service held the previous day was received. A report of the letter ballot of the Sectional Committee relative to the basic formula developed by the Subgroup for use in setting up schedules of pipe wall thicknesses, indicating approval, was made also at that time. This Sectional Committee, at the request of the Sectional Committee on Pipe Flanges and Fittings, had given consideration to the elimination of the $3^1/_2$ in. nominal pipe size from the standards developed by the latter committee. The Secretary reported at the June meeting that a ballot of the members of the Committee had been taken on this subject, and that the results indicated that they were somewhat divided in opinion. Following further discussion at this meeting, the Committee recommended the retention of the $3^1/_2$ in. pipe size in standard weight and extra strong pipe and its elimination from the heavier weight pipe, dimensions for which are to be set up.

Subcommittee on Plan, Scope, and Editing. H. H. Morgan, Chairman. The Subcommittee met in Pittsburgh in March, 1931, and discussed the program and progress of work of the several Subcommittees. It was agreed at that time that arrangements be made for meetings of the Sectional Committee and the two Subcommittees during the month of June in Chicago.

Subcommittee on Pipe and Tubing for Low Temperature Service J. J. Shuman, Chairman, and Subcommittee on Pipe and Tubing for High Temperature Service. J. R. Tanner, Chairman. The two Subcommittees held a joint meeting a day previous to the June, 1931, meeting of the Sectional Committee. Considerable work had been done by these Subcommittees in preparing schedules of pipe wall thicknesses conforming to the basic formula which had been adopted. Tables and graphs illustrating the general scheme of the application of the basic formula to commercial pipe sizes were distributed at the meeting. Both Subcommittees are now at work on the extension and completion of this study, which will include sizes up to 24 in. O.D. The subject of pipe nomenclature is also receiving the attention of these Committees.

Speeds of Machinery. A. E. Hall, Temporary Chairman. Progress in the work of the Sectional Committee on the Standardization of Speeds of Machinery has been dependent upon the results from the distribution of a questionnaire which was prepared by the Subcommittee on Questionnaire and Canvass to Industry. This Subcommittee held a meeting in December, 1930, and developed a preliminary draft of the questionnaire which was completed and distributed in March, 1931, to approximately 400 manufacturers and users of various types of machinery. The one hundred and sixty-one replies received to this distribution are now being compiled by a committee of one, preparatory to a meeting of the Subcommittee in October. The Subcommittee's report will be used as the basis of the Sectional Committee's first proposal.

Fire Hose Couplings. The American Standard for Fire Hose Coupling Screw Threads was approved and published in May, 1925. Each year since that date has marked a continuing increase in its adoption by cities and towns throughout the United States. The National Board of Fire Underwriters, the Chamber of Commerce of the United States, the A.S.M.E. Local Sections, and many local organizations have cooperated in the promulgation of this standard. A report compiled by the National Board of Fire Underwriters early in the year indicates that 3930 protected cities and towns located in 40 of the 48 states, including the District of Columbia, have adopted the American Standard. The States of Oregon, Massachusetts, Texas, Maryland, and California have passed legislative bills prohibiting the sale, purchase, or use of any fire-fighting apparatus which does not conform to this Standard. The adoption of the American Standard by the State of California, in June, 1931, is largely the result of the activities of the San Francisco Section of the A.S.M.E.

Screw Threads for Hose Couplings. H. W. Bearce, Chairman. The Sectional Committee on the Standardization of Screw Threads for Hose Couplings distributed its preliminary proposal for American Standard Screw Threads for Hose Couplings of $^1/_2$ to 2 in. in diameter in February, 1931, for criticism and comment. The comments received have been studied by the Committee and a revision based on these comments will shortly be submitted to the Sectional Committee for discussion and approval by letter ballot.

Plumbing Equipment. W. C. Groeniger, Chairman. The Sectional Committee on the Standardization of Plumbing Equipment has set up eight subcommittees which are at work developing standards in this field. In January, 1931, a new Subcommittee was appointed, that on Cast Iron Soil Pipe and Fittings. The personnels

of the first four subcommittees are identical with those of the Standing Committees on the same subject of the Division of Simplified Practice, U.S. Department of Commerce.

Subcommittee on Plumbing Code. W. C. Groeniger, Acting Chairman. This Subcommittee, the personnel of which is the same as that of the U.S. Department of Commerce's Subcommittee on Plumbing of the Building Code Committee, is revising its code which was published in 1929. As soon as revised copies are available they will be distributed to members of the Sectional Committee for consideration.

Subcommittee on Brass Plumbing Products. J. L. Murphy, Chairman. In March, 1931, the Chairman distributed to the members of the Subcommittee copies of the preliminary proposals of several of its subgroups. These were for Subgroup No. 1 on Compression Cocks, Washer Screws, Faucets, and Tail Piece Parts; Subgroup No. 3 on Fixture Connections and Fixture Valves; Waste Holes, Plugs, and Connections; Overflows; Subgroup No. 4 on Valves; and Subgroup No. 7 on Nomenclature. For the purpose of discussing these sections the Subcommittee now plans to hold a meeting during the third week in October.

Subcommittee on Copper Water Tube Fittings. F. L. Riggin, Chairman. This Subcommittee distributed a tentative proposal in February, 1931, to approximately 200 manufacturers and users. The comments received are to be considered at a meeting of the Subcommittee in October.

Subcommittee on Cast Iron Soil Pipe and Fittings. J. J. Crotty, Chairman. The Subcommittee was organized in January, 1931, and since then has held five meetings at which tentative proposals were considered by the members. In August a questionnaire was distributed to the manufacturers of soil pipe requesting that they submit to the committee a list of pipe fittings now included in the Soil Pipe Association's Specifications, but which, in their estimation, could be excluded from the proposed American Standard. An investigation is also being made to determine whether it is practical to improve upon the design of certain fittings.

Standardization and Unification of Screw Threads. R. E. Flanders, Chairman. In October, 1930, the Sectional Committee met and reviewed the progress already made by its six subcommittees. At this time also detailed arrangements were made for conducting the "Survey of Screw Thread Practice in the United States," and it was decided that this should be started as soon as practicable. The subject of wood screw standardization was considered, and subsequently a seventh Subcommittee was appointed to investigate this project. During the year three of the subcommittees have met and the following progress is reported.

Subcommittee on Scope, Arrangement, and Editing. R. E. Flanders, Chairman. This subcommittee met in April, 1931, for consideration of the various activities within its scope; one of the most important of these is the following:

Survey of Screw Thread Practice in the United States. At that time considerable progress was reported in the collection of samples for the Screw Thread Survey. Since then all the required samples of threaded product have been collected by the Committee's representative and shipped to the National Bureau of Standards, where the gaging is being done. In all, 161 firms were visited personally and of these 128 contributed samples. The total number of pieces collected and sent to the Bureau of Standards is 7579, comprising on the average 5 pieces each of 1539 individual samples. The expenses of this survey are being met jointly by the Bureau of Standards and the Sectional Committee. The Committee's part has been subscribed by Engineering Foundation and a number of firms which manufacture and use screw threading tools and threaded products. The carrying through of the detailed arrangements, including the financing of the survey, which had been worked out by Subcommittee No. 1 on Plan, Scope, and Editing, was entrusted to a subgroup of three appointed on the authorization of the Sectional Committee. The members of this Subgroup are: R. E. Flanders, C. W. Bettcher, and E. Buckingham.

Subcommittee on Special Threads and the Twelve Pitch Series Except Gages. R. E. Flanders, Temporary Chairman. In April, 1931, this Subcommittee held a meeting and decided to set up a 12-pitch series having the following characteristics: (1) tolerances adaptable to general purpose applications; (2) tolerances on the threads in the nuts limited to Class 2; (3) tolerances on the screw threads given in Classes 2 and 3. It also accepted as a part of its immediate work the setting up of an 8-pitch thread series in diameters from 1 to 3 in., inclusive. This latter series is intended primarily for the use of the piping industry.

Subcommittee on Wood Screws. A. Boor, Chairman. At its meeting held in April, 1931, this Subcommittee discussed the possibility of standardizing the minor diameters of wood screws. After reviewing certain data on the present-day practice, recommendations were made on the proportion of minor to major diameters, and it was decided to canvass the manufacturers on this point. It is expected that a definite conclusion will be reached, on the basis of the replies to the questionnaire, at the next meeting.

Rolled Threads for Screw Shells of Electric Sockets and Lamp Bases. R. E. Meyers, Chairman. During the year the Sectional Committee completed the proposed American Standard for Rolled Threads for Screw Shells of Electric Sockets and Lamp Bases. It was submitted to the A.S.A. in September, 1931, for final approval and designation as an "American Standard." Following the granting of this approval the standard will be printed in pamphlet form.

In February, 1931, the members of the Sectional Committee on Rolled Threads for Screw Shells of Electric Sockets and Lamp Bases were designated by the U.S. National Committee of the International Electrotechnical Commission as a Committee of Advisors on Lamp Holders and Bases to the U.S.N.C., to prepare the United States proposal for the September, 1931, meeting of I.E.C. Advisory Committee No. 6, Lamp Holders and Bases, in London. Two meetings of the Committee of Advisors were held, one in May and another in July, 1931. At the latter meeting the committee prepared a report recommending to the U.S.N.C. that the proposed American Standard be adopted as the International Standard for shallow threaded shells and that the European standard be adopted as the International Standard for deep threaded shells. This recommendation was made after careful consideration of American and European practice, which the Committee believed could not be unified at the present time.

Stock Sizes, Shapes, and Lengths for Hot and Cold Finished Iron and Steel Bars. F. H. Frankland, Temporary Chairman. At the time of the organization meeting of the Sectional Committee on the Standardization of Stock Sizes, Shapes and Lengths for Hot and Cold Finished Iron and Steel Bars, in June, 1930, it was recommended that several additional organizations be invited to appoint official representatives on the Committee. This took a longer time than usual, so that it was not until June, 1931, that the Chairman was able to complete the personnels of the three subcommittees on (1) Hot Rolled Steels; (2) Cold Finished Steels; and (3) Hot Rolled Iron.

Subcommittee on Cold Finished Steels. L. E. Creighton, Temporary Chairman. A meeting of this subcommittee has been set for October 20.

Pressure and Vacuum Gages. M. D. Engle, Temporary Chairman. Sponsorship was accepted by the A.S.M.E. for this project in June, 1930, and 55 associations and societies were requested to appoint representatives to this Sectional Committee. The organization meeting was held in December, 1930, at which time the scope as proposed by the American Standards Association was approved by the Committee without change. At a meeting of Subcommittee No. 1 on Plan and Scope in June three subcommittees were appointed to develop the several sections of the proposed standard.

Subcommittee No. 2. C. F. Schwep, Chairman. Subcommittee No. 2 was appointed to develop the proposed section on definitions, specifications, and rules for installation and use. In July, 1931, this committee held its first meeting, and in September the first preliminary proposal was sent to its members.

Subcommittee No. 3. H. B. Reynolds, Chairman. This Subcommittee plans to meet during the fall group of Technical Committee meetings in October. Its scope is to include gage sizes and mounting dimensions; (suggested list of preferred sizes); size and type of connections of gages and cocks; indicator hands (balance—interchangeability); stop pins (when and were to be used); bezel rings and methods of attachment; and safety features for high pressure gages.

Subcommittee No. 4. O. J. Hodge, Chairman. The section on dial ranges; recommended dial ranges for various working pressures; graduations, markings, and space for trade names; accuracy requirements for different services; method of expressing the degree of accuracy; and method of testing (laboratory and field), has been assigned to this subcommittee. No meetings have been held so far.

Foundry Equipment. E. S. Carman, Temporary Chairman. The sponsorship for this project was accepted by the American Foundrymen's Association and the A.S.M.E. in February, 1931. In the same month letters were addressed to 28 associations and societies requesting them to appoint official representatives to the Sectional Committee. The organization meeting was held in May, 1931, at which time the Committee voted to change its name to the Sectional Committee on the Standardization of Foundry Equipment and Supplies. The work of developing the proposed standard was divided at that meeting into three parts to be handled by subcommittees to be appointed by the Chairman. At this meeting the Committee also

voted to request six additional organizations to appoint representatives. As soon as these appointments are completed the Chairman will name the members of the subcommittees.

Leather Belting. J. C. Mattern, Temporary Chairman. Sole sponsorship for this project was accepted by the A.S.M.E. in January, 1931. The preliminary organization of the Sectional Committee on the Standardization of Specifications for Leather Belting was immediately begun, and in May, 1931, the Committee held its first meeting. A definite outline of procedure was developed at this meeting, and two Subcommittees were appointed, one on Standard Specifications and the other on Recommendations for Selection, Care, and Installation.

Subcommittee on Standard Specifications. R. C. Bowker, Chairman. The first meeting of this Subcommittee is scheduled to be held in November, 1931.

Subcommittee on Recommendations for Selection, Care, and Installation. G. A. Schieren, Chairman. On the same day that the Sectional Committee was organized the Subcommittee on Recommendations for Selection, Care, and Installation held its first meeting and elected permanent officers. As the first step in the development of its proposal the Subcommittee is endeavoring to secure copies of all specifications having a bearing on its work. This data will form the basis of its preliminary recommendations. The Chairman has planned for a meeting early in November.

A.S.M.E. Committee on Shaft Couplings. D. J. McCormack, Chairman. During the early part of the year an effort was made to correlate the work of the A.S.M.E. Committee on Shaft Couplings with that of one of the several Sectional Committees, organized under the American Standards Association procedure, whose scope and personnel might be appropriate to a review of a proposed standard on shaft couplings. This endeavor, however, proved to be impracticable, and it was decided that the Committee's proposal, after approval by the A.S.M.E., should be initiated into the A.S.A. procedure under the "Proprietary Standards" method. In July, 1931, printer's proof copies of the proposed standard for Integrally Forged Flange Type Shaft Couplings for Hydro-Electric Units, developed by this A.S.M.E. Committee, were distributed to the Committee members and to other interested persons for criticism and comment. The replies received as a result of this distribution are now in the hands of the Committee for consideration, and formal approval by the Committee of this proposal for submittal to the A.S.M.E. Council is expected at an early date. When it has been accepted by the A.S.M.E. it will be transmitted to the American Standards Association for approval and designation as an American Standard.

Standards Published. The following standards developed by these Committees have been published by the A.S.M.E.

Cold Finished Shafting, Diameters and Lengths (B17a-1924)
Square and Flat Stock Keys, Widths and Heights (B17b-1925)
Plain Taper Stock Keys, Square and Flat (B17d-1927)
Gib Head Taper Stock Keys, Square and Flat (B17e-1927)
Code for Design of Transmission Shafting (B17c-1927)
Woodruff Keys, Keyslots, and Cutters (B17f-1930)
Tolerances, Allowances, and Gages for Metal Fits (B4a-1925)
Spur Gear Tooth Form, 14½ Degree Composite System, 20 Degree Stub Involute System (B6b-1927)
American Standard Screw Threads for Bolts, Machine Screws, Nuts, and Commercially Tapped Holes (B1a-1924)
Cast Iron Pipe Flanges and Flanged Fittings; All Sizes for Maximum Working Saturated Steam Pressure of 25 Lb. per Sq. In. (Gage); All Sizes for a maximum gas working pressure of 25 Lb. per Sq. In.; Sizes 36 In. and Smaller for Maximum Non-Shock Working Hydraulic Pressure of 43 Lb. per Sq. In. (Gage) at or near the ordinary range of air temperatures. (B16b2-1931)
Cast Iron Pipe Flanges and Flanged Fittings; All Sizes for Maximum Working Saturated Steam Pressure of 125 Lb. per Sq. In. (Gage); Sizes 12 Inches and Smaller for Maximum Non-Shock Working Hydraulic Pressure of 175 Lb. per Sq. In. (Gage) at or Near the Ordinary Range of Air Temperatures (B16a-1928)
Cast Iron Pipe Flanges and Flanged Fittings; All Sizes for Maximum Working Saturated Steam Pressure of 250 Lb. per Sq. In. (Gage); Sizes 10 Inches and Smaller for Maximum Non-Shock Working Hydraulic Pressure of 400 Lb. per Sq. In. (Gage) at or near the ordinary range of air temperatures (B16b-1928)
Cast Iron Screwed Fittings, for Maximum Working Saturated Steam Pressure of 125 and 250 Lb. per Sq. In. (Gage) (B16d-1927)
Malleable Iron Screwed Fittings, for Maximum Working Saturated Steam Pressure of 150 Lb. per Sq. In. (Gage) (B16c-1927)
Cast Iron Long Turn Sprinkler Fittings (Screwed and Flanged) for Maximum Hydraulic Working Pressures of 150 and 250 Lb. per Sq. In. (Gage) (B16g-1929)
Steel Pipe Flanges and Flanged Fittings for Maximum Working Steam Pressures of 250, 400, 600, 900, and 1350 Lb. per Sq. In. (Gage) at a Temperature of 750 Deg. Fahr. (B16e-1927)
Small Rivets, 7/16 Inch Nominal Diameter and Under (B18a-1927)
Tinners', Coopers', and Belt Rivets (B18g-1929)
Wrench Head Bolts and Nuts and Wrench Openings (B18b-1927)
Round Unslotted Head Bolts (Carriage, Step, and Machine Bolts) (B18e-1928)
Slotted Head Proportions; Machine Screw, Cap Screws, and Wood Screws (B18c-1930)
Plow Bolts (B18f-1928)
Track Bolts and Nuts (B18d-1930)
Scheme for Identification of Piping Systems (A13-1928)
T-Slots, Their Bolts, Nuts, Tongues, and Cutters (B5a-1927)
Tool Holder Shanks and Tool Post Openings (B5b-1929)
Taps—Cut and Ground Thread (B5e-1930)
Milling Cutters—Nomenclature, Diameters, Thickness, and Other Important Dimensions (B5c-1930)
Symbols for Hydraulics (Z10b-1928)
Aeronautical Symbols (Z10e-1930)
Mathematical Symbols (Z10f-1928)
Symbols for Photometry and Illumination (Z10d-1930)
Symbols for Heat and Thermodynamics (Z10c-1931)
Fire Hose Coupling Screw Thread for All Connections Having Nominal Inside Diameters of 2½, 3, 3½, and 4½ Inches. (B26-1925)

Respectfully submitted,
LEWIS K. SILLCOX, *Chairman*
H. BIRCHARD TAYLOR
WILLIAM S. MONROE
EARLE BUCKINGHAM.

SAFETY COMMITTEE

The standing Committee on Safety has continued throughout the year its efforts in the promotion of industrial safety through the activities of the Society. A Symposium on Industrial Accident Prevention was held during the Annual Meeting of the Society in December, 1930. Half-day sessions on Safety were planned for the Birmingham, Hartford, and Kansas City meetings, as well as for this December's Annual Meeting of the Society; however, it was not found possible to carry out this program, except for the Birmingham Meeting. A joint session with the National Safety Council was held at the Birmingham Meeting in April, 1931. Papers were read on the economic aspects of accident prevention through engineering in the iron and steel industry. As a result of the efforts of the Committee an active part was taken by the Society in the New York Safety Conference, held in New York in February, 1931, in which 42 organizations cooperated. Chairman Mowery arranged for the five-minute talk on "Relation of Safety in the Printing Industry," given at the Printing Industries Session in December, 1930. Plans have been made also for a talk by Frances Perkins, Commissioner of Labor of the State of New York, on "State Labor Departments and Professional Engineers—Cooperation Essential to Progress in Accident Prevention" during the Annual Meeting, December, 1931.

The Committee has requested authors of papers to be given at the various A.S.M.E. meetings to deal with the safety aspects of their subjects. This plan is intended to take the place of the five-minute talks previously given at such times. It was further suggested that the economies of accident prevention should be stressed in articles in *Mechanical Engineering*, and that books on machine design should be reviewed from the safety point of view in *Mechanical Engineering*.

The Committee has proposed the appointment of a joint A.S.M.E. and N.S.C. committee to promote ways and means of increasing the interest of both organizations' membership in accident prevention, but after due consideration and discussion, it was decided that the existing set-up is best, whereby the A.S.S.E. Committee on Relations With Other Engineering Societies shall continue to function for the N.S.C. and the Standing Committee on Safety for the A.S.M.E. The Chairman also reports that the A.S.S.E. Committee on Cooperation With Other Engineering Societies, as a result of its recent experience, suggests the following activities as likely to create a greater interest within those national bodies in advancing the cause of accident prevention: (1) Endeavor to secure the appointment by each national engineering society of an accident prevention committee; (2) arrange for joint sessions on safety as an integral part of the annual, mid-year, or regional meetings of the national societies or their divisions; (3) contact the educational committees of the national societies (where such committees have been appointed)

to advance the project of inclusion of safety engineering in the curricula of technical schools and colleges.

Last spring the organization of a special committee to develop a code for aircraft safety and inspection, as suggested by the Professional Division on Aeronautics, was approved by the Committee, and in June, 1931, a committee of six was appointed by the President. The Code is to include construction, maintenance, and operation of aircraft from the viewpoint of safety in its relation to personnel, cargo, and the public—both on the ground and in the air.

During the year articles totaling ten pages of text have been published in *Mechanical Engineering*.

Of the 50 safety code committees now functioning under the procedure of the American Standards Association, five are sponsored solely or jointly by the A.S.M.E. These are:

Sectional Committee on a Safety Code for Mechanical Power Transmission Apparatus
Sectional Committee on a Safety Code for Elevators
Sectional Committee on a Safety Code for Machinery for Compressing Air
Sectional Committee on a Safety Code for Conveyors and Conveying Machinery
Sectional Committee on a Safety Code for Cranes, Derricks, and Hoists.

Personnel

The Sectional Committees on safety codes sponsored by the A.S.M.E. now have a membership of 220. Of this number 90 are members of the Society. These five Committees have subdivided their work among 23 subcommittees and subgroups, making a total of 28 committees at work on this safety program.

Activities of Sectional Committees

Mechanical Power Transmission Apparatus. C. B. Auel, Chairman. The Safety Code for Mechanical Power Transmission Apparatus was originally completed by the Sectional Committee in 1923, revised and raised to the status of an American Standard in 1927. Late in 1930 the State of New Jersey Department of Labor reprinted this code in its entirety. A revision of this Code, which is to include a chapter on mechanical power control, is now in progress.

Elevators. S. W. Jones, Chairman. The Sectional Committee completed and approved the second revision of the Safety Code for Elevators, Dumbwaiters, and Escalators in February, 1931, and after formal approval by the sponsor organizations the Bureau of Standards, the American Institute of Architects, and The American Society of Mechanical Engineers, it was approved by the American Standards Association in July.

The Subcommittee on Research, Interpretations, and Recommendations, M. H. Christopherson, Chairman, formed after the publication of the 1925 revision of the Code, has continued its monthly meetings.

Subcommittee on Elevator Inspectors' Handbook. K. A. Colahan, Chairman. In December, 1930, printer's proofs of Part 1, Routine Inspection of the Elevator Inspectors' Handbook, were sent to the Subcommittee for letter ballot approval. Before the ballot was completed, however, developments indicated that it would be necessary for the committee to await the results of certain cable tests before the paragraph on Cable Inspection could be approved. These tests are now being developed and will soon be submitted to the subcommittee for approval.

Conveyors and Conveying Machinery. C. H. Newman, Chairman. Two of the Subcommittees of the Sectional Committee on a Safety Code for Conveyors and Conveying Machinery submitted redrafts of their sections of the Code this spring. These sections deal with gravity conveyors, chutes and live roll conveyors, cable-dragline Conveyors, Part 1 and 2. Subcommittees are actively engaged in preparing reports on Belt Scraper and Screw Conveyors, also Chain Elevators and Conveyors, which are expected to be ready for presentation at the Annual meeting.

Cranes, Derricks, and Hoists. J. C. Wheat, Chairman. The Chairman reports that the three subcommittees on (1) overhead and gentry cranes, (2) locomotive and tractor cranes, and (3) jacks have completed their sections of the code. These are now in the hands of the editing committee. The two other subcommittees on (4) derricks and hoists, and (5) equipment for cranes and hoists, expect to release their tentative proposals about October first. The Editing Committee has been delayed in its work, due to the extra work put on its Chairman, Commander Church, of the U. S. Navy Bureau of Yards and Docks, by rush construction work planned to relieve the unemployment situation.

Other Safety Code Committees. In addition to these Committees, the Society has representation on 26 other safety code committees, thirteen of which have completed codes. These committees are as follows:

Safety Code Correlating Committee
Sectional Committee on Safety Code for Abrasive Wheels
Sectional Committee on Safety Code for Floor Wall Openings, Railings, and Toe Boards
Sectional Committee on Safety Code for Industrial Sanitation
Sectional Committee on Safety Code for Lighting Factories, Mills, and Other Work Places
Sectional Committee on Safety Code for Forging and Hot Metal Stamping
Sectional Committee on Safety Code for Ladders
Sectional Committee on Safety Code for Logging and Sawmill Machinery
Sectional Committee on Safety Code for Aeronautics
Sectional Committee on Safety Code for Textiles
Sectional Committee on Underground Power Transmission and Power Equipment for Metal Mines
Sectional Committee on Safety Code for Machine Tools
Sectional Committee on Safety Code for Paper and Pulp Mills
Sectional Committee on Safety Code for Power Presses, and Foot and Hand Presses
Sectional Committee on Safety Code for Rubber Machinery
Sectional Committee on Safety Code for Walkway Surfaces
Sectional Committee on Safety Code for Amusement Parks
Sectional Committee on Safety Code for Window Washing
Sectional Committee on Safety Code for Color for the Identification of Gas Mask Canisters
Sectional Committee on Safety Code for Construction Work
Sectional Committee on Safety Code for Protection of Industrial Workers in Foundries
Sectional Committee on Safety Code for Prevention of Dust Explosion
Sectional Committee on Safety Code for Ventilation
Sectional Committee on Safety Code for Mechanical Refrigeration
Special A.S.S.E. Committee on Low Voltage Electrical Hazard.

Two of the five sectional committees have approved codes which have been published by the Society; these are:

Safety Code for Mechanical Power Transmission Apparatus (B15-1927)
Elevator Safety Code (A17-1931).

Respectfully submitted,

Harold W. Mowery, *Chairman*
Lew R. Palmer
Lewis Price
Thomas A. Walsh, Jr.
Martin H. Christopherson.

POWER TEST CODES

The Committee on Power Test Codes presents the following report for the year ending September 30, 1931.

Test Codes Completed

During the year just closed the Test Code for Liquid Fuels and the Test Code for Atmospheric Water-Cooling Equipment were completed and printed in pamphlet form. In addition, several sections of Instruments and Apparatus were completed and issued in pamphlet form, namely, Part 3, Temperature Measurement—Chapter 1, General, Chapter 5 on Pyrometric Cones, Chapter 6 on Liquid-in-Glass Thermometers, and Chapter 7 on Bourdon Tube Thermometers; Part 11, Determination of Quality of Steam; Part 13, Speed Measurements; Part 16, Density Determinations; and Part 17, Determination of the Viscosity of Liquids.

Twenty of the proposed 24 test and supplementary codes and 12 of the proposed 34 sections of Instruments and Apparatus have been completed and published during the period 1922–1931, as follows:

Code on General Instructions
Code on Definitions and Values
Test Code for Solid Fuels
Test Code for Liquid Fuels
Test Code for Stationary Steam-Generating Units
Computation and Report Sheets—(Stationary Steam-Generating Units)
Test Code for Reciprocating Steam Engines
Test Code for Steam Turbines
Test Code for Reciprocating Steam-Driven Displacement Pumps
Test Code for Centrifugal and Rotary Pumps
Test Code for Displacement Compressors and Blowers
Test Code for Feedwater Heaters

Test Code for Condensing Apparatus
Test Code for Atmospheric Water-Cooling Equipment
Test Code for Refrigerating Systems
Test Code for Evaporating Apparatus
Test Code for Steam Locomotives
Test Code for Gas Producers
Test Code for Internal-Combustion Engines
Test Code for Hydraulic Power Plants and Their Equipment
Test Code for Speed-Responsive Governors

Instruments and Apparatus:
- Part 1, General Considerations
- Part 2, Pressure Measurements;
  - Chapter 1, Barometers
  - Chapter 2, Tables, Multipliers, and Standards for Barometers, Mercury, and Water Columns and Pressure Measurements
- Part 3, Temperature Measurement;
  - Chapter 1, General
  - Chapter 5, Pyrometric Cones
  - Chapter 6, Liquid-in-Glass Thermometers
  - Chapter 7, Bourdon Tube Thermometers
- Part 11, Determination of Quality of Steam
- Part 13, Speed Measurements
- Part 16, Density Determinations
- Part 17, Determination of the Viscosity of Liquids
- Part 21, Leakage Measurement;
  - Chapter 1, Condenser Leakage Tests

During the year two of the original codes in the series of test and supplementary codes were also completely revised in the light of current practice and reprinted in pamphlet form. These were the Code on Definitions and Values and the Test Code for Solid Fuels. The Computation and Report Sheets (1929) of the Test Code for Stationary Steam-Generating Units were also revised in line with the recently revised edition of the corresponding code.

Personnel Changes

The Committee records with deep regret the deaths during the year of three of its members who have been active in the work of the Individual Committees: Prof. S. W. Parr, who was a member of Committee No. 3 on Fuels, and Messrs. Charles Prentice Turner and J. T. Wilkin, both of whom were members of Committee No. 9 on Displacement Compressors and Blowers.

Additions have been made by appointment to the individual committees of Frank G. Philo on Committee No. 3 on Fuels and Prof. William A. Sloan on Committee No. 19 on Instruments and Apparatus.

Mr. Ely C. Hutchinson, a member of Committee No. 18 on Hydraulic Power Plants and Their Equipment, was appointed to succeed H. Birchard Taylor as Chairman of this Committee.

The 20 Individual Committees and the Main Committee on Power Test Codes now include in their personnel 119 members of the Society and 12 non-members.

Committee Activity

Committee meetings were held during the year by Committee No. 3 on Fuels, No. 10 on Centrifugal and Turbo-Compressors and Blowers, and No. 6 on Steam Turbines for the purpose of discussing matters pertinent to the revision and further development of their respective codes.

Individual Committee No. 10 on Centrifugal and Turbo-Compressors and Blowers has completed a fourth draft of its Code. The Committee, however, has learned that difficulties have been experienced with tests carried out in accordance with the section of the proposed Code dealing with the testing of fans. This section is based on a test code originally formulated by the American Society of Heating and Ventilating Engineers and the National Association of Fan Manufacturers.

When finally revised page proofs of the Test Code for Complete Steam-Electric Power Plants were presented for final approval, the Main Committee found a number of inconsistencies and omissions of a technical nature. The Code, therefore, was referred back to Individual Committee No. 11 for the purpose of giving consideration to the corresponding suggestions.

A résumé of the progress which has been made during the past year in the preparation of the various parts and chapters of Instruments and Apparatus is as follows: Part 2, Pressure Measurement—Chapter 2 on Static and Total Pressure, Static Holes and Tubes, Impact Tubes, and Chapter 3 on Pipes for Pressure Measurement appeared in the July, 1931, issue of *Mechanical Engineering;* Part 5 on Measurement of Quantity of Material appeared in the August, 1931, issue; Part 9, Heat of Combustion in the December, 1930, issue; Part 16, Density Determinations in the February, 1931, issue, and Part 20, Smoke-Density Determinations in the November, 1930, issue. The development of the following parts and chapters has progressed appreciably within the past year; Part 3, Temperature Measurement—Chapter 2 on Radiation Pyrometers, and Chapter 8 on Optical Pyrometers; Part 4 on Head Measuring Apparatus; Part 10 on Flue Gas Analysis; Part 12 on Measurement of Time; Part 14 on Measurement of Surface Areas; Part 18 on Humidity Determinations; and Part 21, Leakage Measurement—Chapter 2 on Boiler, Piping, and Engine Leakage.

The publication of abstracts of preliminary drafts of the Power Test Codes and other related material in *Mechanical Engineering* for the year has filled 16 pages.

Boiler Heating Surface

Since the publication of the 1929 edition of the Test Code for Stationary Steam-Generating Units some considerable differences of opinion have developed in industry regarding the determination of the heating surface of certain types of water-tube boilers. This discussion was brought to the attention of Individual Committee No. 4 on Stationary Steam-Generating Units. Before making further changes in their Code, the members of the Committee requested an expression of opinion by the Main Committee on the exact definition of boiler heating surface. The Main Committee voted that there is no deviation between the amount of the boiler heating surface as defined by the Code on Definitions and Values, the Test Code for Stationary Steam-Generating Units, and the Boiler Construction Code, and that the total boiler heating surface as thus defined is that surface which is between the fluid to be heated on one side and the hot gases or refractories on the other, the area measured on the heat receiving side, the fluid being part of the circulating system whatever the nature of the fluid and whether it be liquid or vapor.

Throttle and Exhaust Pressure

During the year considerable correspondence passed between the members of Individual Committee No. 5 on Reciprocating Steam Engines and the Main Committee relative to the addition of a section to the Test Code for Reciprocating Steam Engines dealing with the measurement of throttle pressure and exhaust pressure. Inasmuch as the Committee was not in a position to submit a unanimous report to the Main Committee the latter group undertook to set up certain definitions for admission or throttle pressure and back or exhaust pressure which it believes will meet the present need for reciprocating steam engines.

The Main Committee has requested Committee No. 5 to revise the Test Code for Reciprocating Steam Engines, bringing its context and form in line with the several codes in this field which have been formulated since this Code was completed and published. The present differences lie largely in definitions of load—particularly electrical loading—and in the rules for corrections which are being urged by the International Electrotechnical Commission.

Graphical Symbols

Sketches often play a large part in the negotiations for complex power-plant equipment. Consequently the use of conventionalized graphical representations of the various pieces of apparatus forming part of these installations has been made evident. A set of 20 standard graphical symbols for heat-power apparatus was adopted by Advisory Committee No. 5 on Steam Turbines of the International Electrotechnical Commission at its meeting in Stockholm in July, 1930. This list of symbols was, accordingly, given careful consideration by the Committee on Definitions and Values and has been adopted for use with the A.S.M.E. Power Test Codes.

Under the procedure of the American Standards Association, the Sectional Committee on Scientific and Engineering Symbols and Abbreviations developed standards for graphical symbols for electric power apparatus and wiring. A selection from this list was made and included in the June, 1931, revision of the Code on Definitions and Values.

Reproduction of A.S.M.E. Power Test Code

Frequent requests have been received by the Society for permission to reprint the A.S.M.E. Power Test Codes in whole or in part. The Main Committee recommended that the Society should grant permission for the reproduction of abstracts of these codes and supplementary material in textbooks and trade literature, provided that (1) attention is called to the fact that the material is reproduced in abstract and (2) that full reference to the originating source is given. This latter is important since all of these codes are in a constant state of flux and each reprinting is in reality a revision.

Principles Underlying the A.S.M.E. Power Test Codes

During the year the Committee has been giving considerable thought to a statement dealing with the principles which should underly the formulation and use of the A.S.M.E. Power Test Codes which was presented by Francis Hodgkinson. Copies of Mr. Hodgkinson's statement and recommendations were first sent to the entire membership of the Main Committee and the Chairman of the 20 individual committees for review and study preparatory to a full discussion at the May 25th meeting of the Committee. At this meeting the Main Committee reaffirmed the fundamental objectives and purposes of the codes adopted in 1918 and since, and endorsed certain modifications in their make-up, the same to apply to revisions of existing codes and the preparation of new codes.

A special subcommittee consisting of F. Hodgkinson, Chairman, C. Harold Berry, C. F. Hirshfeld, E. B. Ricketts, and W. M. White was appointed to study these principles in detail and to amend, if necessary, the policy to be followed henceforth in the preparation of new or revisions of existing power test codes. This special committee has completed its report, which will be submitted to the October, 1931, meeting of the Main Committee for final approval and subsequent distribution to the entire membership of the Power Test Codes Committee as to the new policy of the Committee.

National Contacts

The Committee this year has corresponded with the American Gas Association relative to the desire of the newly formed A.G.A. Subcommittee on Approval Requirements for Industrial Gas Boilers to secure information on an acceptable and recognized method of running efficiency tests and rating of gas-fired boilers.

Due to the fact that Individual Committee No. 3 on Fuels was best qualified to negotiate with the A.S.T.M. special committee which has been organized to give consideration to the development of definitions for net calorific value and gross calorific value of fuels, Prof. W. J. Wohlenberg, Chairman of the Committee, was appointed by the President as the A.S.M.E. representative, on the recommendation of the Main Committee. This project was brought to the attention of the A.S.T.M. through the American Committee of the World Power Conference.

International Electrotechnical Commission

Through membership on the U.S. National Committee of the I.E.C., the Society and the Main Committee on Power Test Codes has been actively engaged during the year in assisting to bring about international agreements on acceptance tests for steam turbines and internal-combustion engines. As previously reported, the Secretariat for the Advisory Committees on these types of prime movers is held by the United States. The Society was represented this year on the U. S. National Committee by Fred R. Low, William F. Durand, Francis Hodgkinson, C. Harold Berry, Harvey N. Davis, Ely C. Hutchinson, Irving E. Moultrop, and Paul Diserens.

Steam Turbines

In February, 1931, finally corrected proofs of Part I, "Specification" and Part II, "Rules for Acceptance Tests" of the I.E.C. Publication on Steam Turbines were released by the Secretariat for final publication. Since then, in July, 1931, the Central Office of the International Electrotechnical Commission completed the printing and distribution.

In July the Secretariat, of which Dr. F. R. Low is Director, mailed to the ten member countries of Advisory Committee No. 5 on Steam Turbines, printer's proofs of the Supplementary Notes to Section 4, Instruments and Methods of Measurement of Part II. This latter document consists of a revision of Appendix E, Supplementary Notes in accordance with agreements reached in Stockholm, July, 1930, and is now ready for further discussion by the members of the Advisory Committee.

While the two completed documents on Steam Turbines have been approved by the Advisory Committee and the I.E.C., a question was raised as to the desirability of increasing the scope of the Rules to include other types of steam turbines. In accordance with instructions, the Secretariat referred the matter to the member nations for recommendations. When these comments are received the Secretariat will prepare documents for further discussion by Advisory Committee No. 5 concerning proposals for increasing, or otherwise, the scope of the Rules upon which agreements already have been reached.

The French delegate at Stockholm introduced a paper on "A Rational Definition of Steam Turbine Efficiencies." A translation of this article was made by the Secretariat and circulated to the National Committees for their consideration and recommendation.

Inasmuch as the technique of flow measurement by means of tubes, nozzles, and orifices was somewhat in a state of flux, the material on flow measurement before the Advisory Committee was referred by the Secretariat to the International Standards Association with the request that they propose insertions or deletions which may be considered advisable.

Internal-Combustion Engines

At the Stockholm meeting, July, 1930, some of the documents before Advisory Committee No. 19 on Internal-Combustion Engines were discussed, but no decisions were reached. It was agreed that the Secretariat would transmit to the National Committees of the ten member nations a résumé of that discussion, requesting their recommendations concerning these proposals. This résumé was prepared by Francis Hodgkinson, Director of Secretariat, and distributed to the member nations under date of December 13, 1930. Since that time, the Secretariat has received the German Rules for Acceptance Tests of Gas and Internal-Combustion Engines. The German National Committee and the British National Committee have issued their comments in response to the Secretariat's letter.

On June 1, 1931, the Secretariat again requested the member nations to expedite the transmission of their recommendations. At the end of a reasonable time the Secretariat will proceed to prepare for future discussion a new document for Part I, "Specification," reconciling, as far as possible, the views of all the member nations. This will replace the corresponding documents now before the Advisory Committee.

Hydraulic Turbines

It will be recalled that the present I.E.C. Publication (No. 41) on the Testing of Hydraulic Turbines was completed by Advisory Committee No. 4 on Hydraulic Turbines at Bellagio, September, 1927, under Dr. Durand's able leadership and adopted by the Plenary Meetings of the I.E.C. during the same month.

Under date of February 15, 1930, the Secretariat addressed a letter to the delegates and secretaries of the 22 National Committees of the I.E.C. inquiring if, during the past two years, the hydraulic engineers of the several countries have put the provisions of this document into practice in national and international commerce, and if there was a desire to expand this I.E.C. publication. The replies received to the Secretariat's letter have been few and very non-committal. Under these circumstances no attempt was made to arrange for a meeting of Advisory Committee No. 4 on Hydraulic Turbines during the Scandinavian Meeting in June, 1930. Since that time, however, the Secretariat has decided to proceed with redrafting the Publication No. 41 along the lines suggested.

For some time past Dr. Durand has felt that he should retire from the directorship of this activity, leaving it to some one preferably in the East to carry on. After careful consideration on the recommendation of Dr. Durand, Dr. Sharp, President of the U. S. National Committee, appointed Ely C. Hutchinson in Dr. Durand's stead as Director of the Secretariat on Hydraulic Turbines. It is expected that the preliminary work of redrafting the publication on the Testing of Hydraulic Turbines will begin very shortly.

Respectfully submitted,

Fred R. Low, *Chairman*

C. Harold Berry	David S. Jacobus

George A. Horne	Walter J. Wohlenberg.

BOILER CODE

The Boiler Code Committee submits the following report for the fiscal year ending September 30, 1931.

During this period the Committee held nine regular meetings, two of which were two-day meetings, which were devoted to interpretations of the Code and to the consideration of revisions and addenda to the various sections.

As stated in the 1930 Annual Report, the Committee has had under consideration rules for the fusion welding of drums or shells of power boilers and for unfired pressure vessels. These rules received widespread attention. As a result of the comments and criticisms received, the revised rules were published in the June issue of *Mechanical Engineering* and were adopted by Council as a standard of the Society on July 7, 1931.

The Rules for Fusion Welding of Drums or Shells of Power Boilers require the highest type of welding. The use of X-ray apparatus is specified for examining the soundness of all longitudinal and circumferential welded joints up to a limiting thickness, beyond which a manufacturer shall have first demonstrated his ability to produce sound welds in boiler drums or shells of a thickness that have been X-rayed. The limiting thickness specified represents the maximum practical capacity of X-ray equipment at the present time. It is stated in the Code that this limiting thickness will be increased when evidence is submitted to the Boiler Code Committee that X-ray or similar means are developed that can be commercially applied to greater thicknesses. All such drums and shells must be stress relieved by heating them to a specified temperature for a specified time. Searching physical tests are required of the weld metal, and every effort has been made to formulate a Code which will result in safety. It is an interesting fact that none of the many discussions received by the Committee has questioned the safety of welded drums or shells constructed in accordance with the Code.

The Rules for Fusion Welding of Unfired Pressure Vessels are the outcome of long and patient work by the Subcommittee on Unfired Pressure Vessels, which cooperated with the Subcommittee on Welding and a number of organizations and persons expert in the field. The rules divide pressure vessels into three classes based on the intended use of the vessel. Class 1, which represents the highest type of construction, is absolutely without limit as to size, working pressure, or the contents within the scope of the Code; Class 2 provides for vessels with a maximum plate thickness of $1^1/_2$ in., which are not to carry lethal gases or liquids, or to be subjected to as severe conditions of service as those built under Class 1. Class 3 provides for vessels with a maximum plate thickness of $^5/_8$ in., which are not to carry lethal gases or liquids, or to be used for the storage of gases or liquids at any temperature materially exceeding their boiling temperature at atmospheric pressure.

Included in the 1931 revisions are rules for the welding of miniature boilers which were incorporated in the Code for Miniature Boilers.

Hearings were granted to the Compressed Gas Manufacturers' Association relative to rules for the storage of liquefied petroleum gases. This Association had formulated "Tentative Regulations for the Design, Installation, and Operation of Liquefied Petroleum Gas Storage Containers and Appurtenant Equipment," and a copy of the proposed rules had been submitted to the Committee for consideration for incorporation in the Code for Unfired Pressure Vessels so that fusion welding for this particular type of container would be recognized.

Conferences followed with representatives of the American Welding Society, the Compressed Gas Manufacturers' Association, the American Boiler Manufacturers' Association, and the National Board of Boiler and Pressure Vessel Inspectors, who rendered valuable assistance and cooperated in the formulation of the rules. A number of others from different industries, such as the petroleum group, cooperated and made valuable contributions.

Another important addition to the Codes has been the incorporation of rules for seal welding of riveted seams of boilers and unfired pressure vessels.

As a result of continued cooperation with the American Society for Testing Materials, many revisions have been made in the Material Specifications Section of the Code. Changes were made in specifications which are identical with those of the A.S.T.M., so as to bring them into conformity with their latest form. During the year new Specifications have been adopted by the A.S.T.M. covering Open-Hearth Iron Plates for Flange Quality and have been accepted by the Boiler Code Committee for incorporation in the Code as Specification S-25.

The Committee has received reports on the tests being made by the Taylor Forge & Pipe Works, Chicago, Ill., in order to supply data for more logical rules on reinforcement of openings than now appear in the Code. The Committee has in the meantime appointed a special committee which is considering this subject with a view to rationalization of the requirements in the Code on such reinforcements.

The Honorary Secretary visited Tulsa and Oklahoma City during the early part of the year for the purpose of investigating the pressure vessel situation there and the application of the Code for Unfired Pressure Vessels to constructions employed in the petroleum industry. This led to a more harmonious understanding between the Committee and the group of manufacturers in that region.

The Committee has made numerous revisions and additions to the various sections of its Code as a result of requests from manufacturers, inspectors, users, and others. These revisions were formally adopted by the Council on July 7, 1931, and distributed in pink-colored addenda sheets.

At the request of the Boiler Code Committee the Council made the following appointments on Subcommittees: F. W. Herendeen, Raymond Newcomb, and W. E. Stark as members of the Subcommittee on Heating Boilers; Paul Diserens as a member of the Subcommittee on Unfired Pressure Vessels. Due to their inactivity in the boiler and pressure vessels industry, Leroy Mikels is no longer a member of the main Boiler Code Committee, and A. S. Kinsey is no longer a member of the Subcommittee on Welding. H. E. Aldrich was elected by the Boiler Code Committee as a member of the Executive Committee.

Respectfully submitted,

F. R. Low, *Chairman*
D. S. Jacobus, *Vice-Chairman*
C. W. Obert, *Hon. Secretary*
H. E. Aldrich
W. H. Boehm
F. S. Clark
F. W. Dean
W. F. Durand

I. E. Moultrop
C. O. Myers
H. B. Oatley
James Partington
C. L. Warwick
H. LeRoy Whitney.

PROFESSIONAL CONDUCT

During the fiscal year 1930–1931 no complaints on professional conduct were received.

The Committee has been engaged in correspondence on some details connected with the development of the Code of Ethics of the Society as a more profound influence upon the engineering profession.

Respectfully submitted,

John Hunter, *Chairman*
William B. Powell
A. G. Christie
H. S. Philbrick
D. Robert Yarnall.

Reports of Meetings

THE following pages present brief reports of meetings of the Society and of its Professional Divisions during 1931. More detailed accounts were published in *Mechanical Engineering* and the *A.S.M.E. News*. The meetings reported here are as follows:

MEETINGS OF THE SOCIETY

Semi-Annual, Birmingham, Ala., April 20–23, 1931
Hartford, Conn., June 1–3, 1931
Kansas City, Mo., September 7–9, 1931
Annual, New York, N.Y., November 30–December 4, 1931.

MEETINGS OF THE PROFESSIONAL DIVISIONS

Aeronautics, Baltimore, Md., May 12–14, 1931
Applied Mechanics, Lafayette, Ind., June 15–17, 1931
Fuels, Chicago, Ill., February 10–13, 1931
Iron and Steel and Machine Shop Practice, Boston, Mass., September 22, 1931
Materials Handling and Management, Cleveland, Ohio, April 13–17, 1931
Petroleum, Elizabeth, N.J., May 5–6, and State College, Pa., May 22, 1931
Printing Industries, Washington, D.C., March 16–17, 1931
Textiles, Providence, R.I., October 6, 1931
Wood Industries, Winston-Salem, N.C., October 15–16, 1931.

Semi-Annual, Birmingham, Ala.

APRIL 20–23, 1931

The Semi-Annual Meeting was reported in the *A.S.M.E. News* of May 7, 1931, with a special report of the conference of Student Branches in the issue of May 22. The attendance of 435 at the Birmingham meeting included 125 students representing twelve southern colleges. At the Council Meeting held on April 20 the establishment of a Student Branch at the University of Alabama was approved. An announcement that the 1932 Semi-Annual Meeting would be held at Bigwin Inn, Ontario, Canada, from June 27 to July 1, was made at the Business Meeting held on April 20. The Nominating Committee selected the following candidates for new officers of the Society in 1931–1932:

President, Conrad N. Lauer
Vice-Presidents, Robert M. Gates, Charles M. Allen, Fred H. Dorner, William B. Gregory
Managers, Alexander J. Dickie, Eugene W. O'Brien, Harry R. Westcott

The following delegates to the American Engineering Council were nominated:

Conrad N. Lauer, Paul Doty, Ralph E. Flanders, C. E. Ferris, L. P. Alford, J. H. Lawrence, R. C. Marshall, Jr., A. A. Potter, W. H. Trask, Jr., E. C. Hutchinson.

A conference of Local Section delegates was held on April 21. The excusions program included all-day trips to the Tennessee Coal, Iron & Railroad Co. and to the Jordan Dam of the Alabama Power Company on the Coosa River. A special program of automobile trips, luncheons, a flower show, and a garden party was arranged for the ladies. The chief social event of the meeting was the banquet on April 22 at which President Roy V. Wright delivered an address on "How About the Humanities?" and Dr. Harrison E. Howe, editor of *Industrial and Engineering Chemistry*, spoke on "Creating New Industries." The program of papers at technical sessions was as follows:

Monday Morning, April 20

HYDRAULICS

(Auspices of Hydraulic Division)

The Application of Hydraulic Laboratory Researches, I. A. WINTER
Calibration of a Large Nozzle, JOHN R. DUPRIEST and JAS. H. POLHEMUS
Present Status of Hydroelectric Development in the Southeastern United States, WM. P. HAMMOND

PROCESS

The Cottonseed-Oil Industry, E. L. CARPENTER and LEO HOLDREDGE

IRON AND STEEL

(Auspices of Birmingham Local Committee and Iron and Steel Division)

Cast Iron Pipe Produced Centrifugally by the DeLavaud Process, S. B. CLARK
New Mono-Cast Centrifugal Pipe Plant, S. D. MOXLEY

Monday Afternoon, April 20

FUELS AND PETROLEUM

(Auspices of Fuels and Petroleum Divisions)

Grindability of Coal, R. M. HARDGROVE
Design Considerations of a Natural-Gas Transmission System, CHAS. W. MERRIAM, JR.

RAILROAD

(Auspices of Railroad Division)

Practical Application of Alloy Steel to Locomotives, C. E. BARBA
Metallurgy in the Railroad Field, A. E. WHITE

SAFETY

Auspices of A.S.M.E. Safety Committee and American Society of Safety Engineers)

Economic Aspects of Accident Prevention in the Iron and Steel Industry, FREDERICK B. WINSLOW
Accident Prevention Through Safety Engineering in the Iron and Steel Industry, DAVID S. ANDERSON

Tuesday Morning, April 21

POWER

(Auspices of Power Division)

Heat Transfer From Condensing Steam to Flowing Water, A. T. BROWN
Design Features and Operating Results of Fairfield Blast-Furnace Power Plant, F. G. CUTLER

MATERIALS HANDLING AND MACHINE SHOP PRACTICE

(Auspices of Materials Handling and Machine Shop Practice Divisions)

Mold-Handling Methods in Foundries, W. L. HARTLEY
Materials Handling in the Automotive Machine Shop, NORMAN H. PREBLE
Preparation and Distribution of Molding Sands, H. L. MCKINNON

TEXTILES

(Auspices of Textile Division)

Control of Picker-Room Humidity, NORMAN E. ELSAS
Trends in the Cotton Textile Industry, C. L. EMERSON

Tuesday Evening, April 21

MANAGEMENT AND AERONAUTICS

(Auspices of Management and Aeronautic Divisions)

Principles of Industrial Plant Location, H. C. RYDING
Southern Air Transport, FREDERIC G. COBURN

Hartford, Conn.

JUNE 1–3, 1931

A report of the Hartford Meeting appeared in the *A.S.M.E. News* dated June 7, 1931. The attendance at the meeting was about 400. A Council Meeting was held on June 1 and a conference of Local Section delegates on the following day. Special excursions were made to plants of the Pratt & Whitney Aircraft Co., Chance Vought Corporation, Royal Typewriter Company, Colt's Patent Fire Arms Mfg. Co., and Pratt & Whitney Co. Several other plants were visited by the ladies, including that of the Fuller Brush Company and the Cheney Silk Mills. An evening program on June 1 included music by the Choral Club and soloists, and addresses by Senator Hiram Bingham on "The Engineer in Public Life" and by F. M. Ryan, of the Bell Telephone Laboratories on "Airplane Telephony." Speakers at the banquet on June 2 were President Wright and E. E. Wilson, president of the Chance Vought Corporation and Sikorsky Aviation Corporation, whose subject was "Aeronautics." The program of technical sessions follows:

Monday Afternoon, June 1

FUELS

(Auspices of Fuels Division)

How Coal Market Values Are Related to Steam-Plant Design and Operation, G. B. GOULD

APPLIED MECHANICS

(Joint auspices of Applied Mechanics Division and Special Research Committee on Strength of Vessels Under External Pressure)

The Collapsing Strength of Steel Tubes, T. MCLEAN JASPER and JOHN W. W. SULLIVAN
The Strength of Thin Cylindrical Shells Under External Pressure, HAROLD E. SAUNDERS and DWIGHT W. WINDENBURG

EDUCATION AND TRAINING

(Auspices of Committee on Education and Training for the Industries)

Training Foremen to Deal With Human Problems in Industry, JOHN A. MCCARTHY
Training Apprentices and Foremen, FRANCES PERKINS

Tuesday Morning, June 2

POWER

(Auspices of Power Division)

Radiant-Superheater Developments, M. K. DREWRY
Load-Deflection Relations for Large Plain, Corrugated, and Creased Pipe Bends, E. T. COPE and E. A. WERT
The Decomposition of Sodium Carbonate in Steam Boilers (by title), REINHOLD F. LARSON

AERONAUTICS

(Auspices of Aeronautic Division)

Recent Developments in Airplane Design, C. J. MCCARTHY
Recent and Future Developments in Aircraft Engines, A. V. D. WILLGOOS
Recent 6000-Mile Flight to and Above Central America, I. I. SIKORSKY
Motion-Picture of Pratt & Whitney Aircraft Corp. and Chance Vought Corporation Factories

MACHINE SHOP PRACTICE (I)

(Joint auspices of Machine Shop Practice Division and Special Research Committee on Cutting of Metals)

Performance of Cutting Fluids, O. W. BOSTON and C. J. OXFORD
The Influence of Chemical Composition and Heat Treatment of Steel Forgings on Machinability With Shallow Lathe Cuts T. G. DIGGES

PETROLEUM AND APPLIED MECHANICS

(Joint auspices of Petroleum and Applied Mechanics Divisions)

Stresses in Dished Heads of Pressure Vessels, CYRIL O. RHYS
Analysis of Stresses in Circular Plates and Rings, E. O. HOLMBERG and KARL AXELSON

Wednesday Morning, June 3

MANAGEMENT

(Auspices of Management Division)

Discussion of Stabilization of Employment, led by HOWELL CHENEY, RALPH E. FLANDERS, W. R. WEBSTER, H. V. COES, HOWARD TILSON, W. H. RASTALL, FAIRFIELD E. RAYMOND

MACHINE SHOP PRACTICE (II)

(Auspices of Machine Shop Practice Division)

Small Tools and Gaging for Interchangeable Manufacture, E. J. BRYANT
Conventional Gages and Their Application to Duplicate Production, THOMAS F. MACLAREN

TEXTILES

(Auspices of Textile Division)

Use of the Butted Seam by Textile Manufacturers, JOHN M. WASHBURN
Use of Counters in the Textile Industry, HARVEY L. SPAUNBURG
Modern Textile Machinery the Result of Research and Comprehensive Engineering, ALBERT PALMER

MECHANICAL SPRINGS

(Joint auspices of Applied Mechanics Division and Special Research Committee on Mechanical Springs)

Progress Report on Comparative Tensile and Shearing Behavior in Springs, Presented by M. F. SAYRE
Stresses in Curved Bars, H. C. PERKINS

Kansas City, Mo.

SEPTEMBER 7–9, 1931

The A.S.M.E. was one of thirteen organizations which participated in the Southwest Power Conference at Kansas City, September 7–11. More than 400 members and guests of the Society attended the Conference, a report of which will be found in the *A.S.M.E. News* for September 22, 1931. The Southwest Power and Mechanical Exposition paralleled the Conference. The A.S.M.E. was represented at the formal opening of the Conference on September 7 by President Wright. Joint luncheons of the participating organizations were held at which the speakers were Captain Theo. Wyman, Jr., U. S. Engineers Corps, on "The Missouri River," and Marshall E. Sampsell, first vice-president of the N.E.L.A. At a joint banquet a lecture and demonstration on "Adventures in Science" was given by E. L. Manning of the General Electric Research Laboratories. Conferences of the Local Section and Student Branch delegates were held, and the afternoons were largely devoted to sightseeing and inspection

trips. The A.S.M.E. program included six technical sessions, as follows:

Tuesday Morning, September 8

POWER

Flour Milling and Power Requirements, GROVER C. MEYER
1400-Lb. Pressure Boiler and Turbine Operation at Northeast Station, J. A. KEETH
Diphenyloxide, JOHN J. GREBE

OIL AND GAS POWER

A Speed Characteristic for Oil Engines, V. L. MALEEV
Diesel Engines as Peak Load Units, S. A. HADLEY
Internal-Combustion Engines for the Oil and Gas Industries, H. F. SHEPHERD

AERONAUTICS (I)

The Design of Practical Light Airplanes, KARL H. WHITE
Aircraft Diesel Engines of High Output, H. C. EDWARDS
Necessary Trends in Airplane Design, WILLIAM B. STOUT

Wednesday Morning, September 9

FUELS

Improvements in Mining and Preparing Strip Coal in the Southwest, L. RUSSELL KELCE
Coal as Basic Fuel, H. KREISINGER
Some General Chemical and Physical Properties of Boiler Room Refractories, J. H. KRUSON

PETROLEUM

Recent Developments in the Liquefied Petroleum Gas Industry, O. M. SETRUM
Building an Empire (film), GEORGE H. BAIRD
Economic Analysis of Pipe-Line Pumping, Round-Table Discussion, led by W. G. HELTZEL

AERONAUTICS (II)

Aviation Insurance, J. B. GUINOTTE
The Maintenance and Overhaul of Aircraft and Engines, H. L. BREDOUW
Airplane Landing Gears, FREDERICK KNACK

Annual Meeting, New York, N.Y.

NOVEMBER 30–DECEMBER 4, 1931

The Fifty-Second Annual Meeting of the A.S.M.E. was reported in the January, 1932, issue of *Mechanical Engineering* and in the *A.S.M.E. News* of December 22, 1931. The attendance at the meeting was approximately 2000. The closing meeting of the 1931 Council was held on November 30, and the organization of the 1932 Council took place on December 4, when new officers as nominated at the Semi-Annual Meeting were installed. The conferences of Local Section delegates began on November 29 and continued on November 30 and December 1. December 2 was "Student Branch Day." A contest in extemporaneous public speaking was held in conjunction with the formal opening of the second exhibition of art for engineers, on Monday evening, November 30.

The series of lectures on "Talking With an Audience," by Dr. S. Marion Tucker, initiated at the 1930 meeting, were continued. The fourth Henry Robinson Towne Lecture was delivered by W. B. Donham, dean of the Graduate School of Business Administration, Harvard University, on the subject, "The Temporary Emergency and Twenty-Year Planning," and the fourth Robert Henry Thurston lecture by Edward L. Thorndike, professor of education, Teachers College, Columbia University, on "Psychology and Engineering." Another outstanding address was made by Frances Perkins, industrial commissioner of the State of New York, on "State Labor Departments and Professional Engineers—Cooperation Essential to Progress in Accident Prevention."

The Annual Dinner was distinguished by the conferring of honorary membership upon Calvin W. Rice, secretary of the Society since 1906. Dr. Karl T. Compton, president of the Massachusetts Institute of Technology, was the chief speaker of the evening. Honorary membership was also conferred upon Dr. Palmer C. Ricketts, president of the Rensselaer Polytechnic Institute, during the Presidents' Night program, and other awards, including three John Scott medals, were made at that time. The presidential address of Roy V. Wright, entitled "The Engineer Militant," will be found elsewhere in this issue of the Record and Index. Many important committee meetings and conferences were held during the week, and the program of excursions included the observatories of the new Empire State Building, the new plant of the Ford Motor Company at Edgewater, N.J., the S.S. *Pennland*, S.S. *Minnetonka*, and the *Aquitania*, as well as several generating stations, and other inspection trips of technical interest. Reports on the Economic Status of the Engineer were presented at the Business Meeting held on December 1 and at the Local Section conference on the preceding afternoon. The Woman's Auxiliary to the A.S.M.E. arranged a program of special events for the ladies.

The program of papers presented at the technical sessions and conferences follows:

Monday Morning, November 30

MACHINE SHOP PRACTICE AND APPLIED MECHANICS

(Auspices of Machine Shop Practice and Applied Mechanics Divisions)

Improved Device for Recording Instantaneous Tool Pressures in Machinability Studies, O. F. GECHTER and H. R. LAIRD
Photoelastic Developments
(*a*) Kinematography in Photoelasticity, MAX M. FROCHT
(*b*) Photoelastic Study of Shearing Stresses in Keys and Keyways, ARSHAG G. SOLAKIAN and GEORGE B. KARELITZ
(*c*) Celluloid as a Medium for Photoelastic Investigation, R. H. G. EDMONDS and B. T. MCMINN

MATERIALS HANDLING

(Auspices of Materials Handling Division)

Rustless-Steel Conveyors—Their Availability, Application, and Use, NIXON W. ELMER
Application and Design of the Floating Drive for Conveyors, N. H. PREBLE
Improved Material-Handling Methods in a Container Plant, H. N. MACDONALD
Progress Report of Materials Handling Division (presented by title)

PROCESS INFORMAL CONFERENCE

(Auspices of Process Committee)

Discussion on a Rational Approach to the Classification of Data of Unit Operations and Industrial Processes, led by H. J. MASSON

Monday Afternoon, November 30

METAL CUTTING

(Auspices of Machine Shop Practice Division and Special Research Committee on Cutting of Metals)

The Elements of Milling, O. W. BOSTON and CHARLES E. KRAUS
Tungsten Carbide and Other Hard Cutting Materials (Progress Report No. 3 of Subcommittee on Metal-Cutting Materials), COLEMAN SELLERS, 3D
Motion Picture: Latest Development in German Machine Tools as Exhibited in Operation at Leipzig Trade Fair

Fluid Meters

(Auspices of Special Research Committee on Fluid Meters)

A Study of Primary Metering Elements in 3-In. Pipe, S. R. Beitler, Paul Bucher, and T. C. Barnes, Jr.
Flow of Steam Through Square-Edge Orifices in 4-In. Line, W. W. Frymoyer and A. Herschel
Reports of Subcommittees on Revision of Part I, Description of Flow Meters and Water Meters, and Influence of Installation

Applied Mechanics

(Auspices of Applied Mechanics Division)

Design of Spring Gears for Exhaust-Turbine Installations, J. Ormondroyd and T. C. Kuchler
Compression of Rectangular Blocks, and the Bending of Beams by Non-Linear Distributions of Bending Forces, J. N. Goodier
Forced Vibrations With Non-Linear Spring Constants, J. P. Den Hartog and Stanley J. Mikina
Progress Report of Applied Mechanics Division, presented by A. L. Kimball

Tuesday Morning, December 1

Industrial Power

(Auspices of Power Division)

Ford Motor Company's 1200-Lb. Steam-Plant Installation, A. R. Smith and H. B. Hanson
Characteristics of a High-Pressure Series Steam Generator (*Contributed by Special Research Committee on Critical Pressure Steam Boilers*), A. A. Potter, H. L. Solberg, and G. A. Hawkins
Once-Through Series Boiler for 1500 to 5000 Lb. Pressure (*Contributed by Special Research Committee on Critical Pressure Steam Boilers*), H. J. Kerr
Progress Report of Power Division

Casting and Machine Design

(Auspices of Machine Shop Practice and Management Divisions)

Machine-Design Management, J. L. Alden
Correlation of Casting Design and Foundry Practice, Alex Taub
Progress Report of Machine Shop Practice Division, presented by F. C. Spencer

Applied Mechanics and Railroads

(Auspices of Applied Mechanics and Railroad Divisions)

Air Resistance of High-Speed Trains and Interurban Cars, O. G. Tietjens and Kenneth C. Ripley
Stresses in Railroad Track, S. Timoshenko and B. F. Langer
Presentation of Resolutions on the Deaths of Prof. Arthur J. Wood and George Hillyer, Jr.
Progress Report of Railroad Division (presented by title)

Lubrication Research

(Auspices of Special Research Committee on Lubrication)

Optimum Conditions in Journal Bearings, Albert Kingsbury
Pressure Distribution in the Oil Films of Journal Bearings, S. A. and T. R. McKee
Oil-Film Pressures in an End-Lubricated Sleeve Bearing, Louis J. Bradford

Wednesday Morning, December 2

Stabilization Symposium

(Auspices of Management Division with cooperation of American Management Association)

Business Stabilization
(*a*) Financial: Some Thoughts on the Solution of the Depression Problem, Paul M. Mazur
(*b*) Industrial: The Unemployed—What Shall We Do With Them? James W. Hook
(*c*) Economic: The Economic Aspects of Stabilization, Virgil Jordan
Progress Report of Management Division (presented by title)

Fuels

(Auspices of Fuels Division and Special Research Committee on Removal of Ash as Molten Slag from Powdered-Coal Furnaces)

Fluxing of Ashes and Slags as Related to the Slagging-Type Furnace, P. Nicholls and W. T. Reid
Progress Report of Fuels Division

Hydraulics (I)

(Auspices of Hydraulic Division)

Progress Report of Hydraulic Division (presented by title)
Hydraulic Butterfly Valves, Ross L. Mahon
Piezometer Investigation, Charles M. Allen and Leslie J. Hooper

Textiles

(Auspices of Textile Division)

Sanforizing Process, Sanford L. Cluett
Cause and Effect of Recent Advances in Textile Machinery, Edwin D. Fowle
Progress Report of Textile Division (presented by title)

Wednesday Afternoon, December 2

Engineering Economics

(Auspices of Management Division with cooperation of American Management Association)

Dividend Programs Related to Depreciation, E. G. Field
Economic Life of Equipment (Contributed by Materials Handling Division and Special Research Committee on Measures of Management), H. O. Vorlander and F. E. Raymond

Lubrication Engineering

(Auspices of Petroleum Division)

Modern Oil-Lubrication Methods as Applied to Rolling-Mill Equipment, Joseph A. Merrill and Edwin M. May
Oil Requirements for Modern Rolling-Mill Oil Circulating Systems, C. M. Larson

Hydraulics (II)

(Auspices of Hydraulic Division)

Leakage Loss and Axial Thrust in Centrifugal Pumps, Alexey J. Stepanoff
Turbulence in Centrifugal Pumps, J. W. Macmeeken

Steam Tables

(Auspices of Special Research Committee on Thermal Properties of Steam)

Report of the Progress at the Massachusetts Institute of Technology, L. B. Smith and F. G. Keyes
Report of the Progress in Steam Research at the Bureau of Standards, N. S. Osborne
Progress in Steam Table Experiments, Harvey N. Davis
Thermodynamic Availability in Power Plants, J. H. Keenan

Thursday Morning, December 3

Central Station Power

(Auspices of Power Division)

Solubility of Calcium Salts in Boiler Water, Frederick G. Straub
Performance of Modern Steam-Generating Units, C. F. Hirshfeld and G. U. Moran
Influence of Inlet Boxes on the Performance of Induced-Draft Fans, Lionel S. Marks and E. A. Winzenburger

Management Research

(Auspices of Management Division with cooperation of American Management Association)

Coordination of Research and Engineering With Production and Sales, Carl L. Bausch

The Coordination of Research, Sales, and Production, RICHARD F. WILDER

SYMPOSIUM ON STEEL MILL BEARINGS

(Auspices of Iron and Steel Division and Special Research Committee on Heavy Duty Anti-Friction Bearings)

Straight Copper-Lead Alloys Versus Leaded Solid-Solution Bronzes for Heavy-Duty Bearings, F. R. HENSEL and L. M. TICHVINSKY
Millwright Bearings for Roll Necks of Medium-Sized Rolling Mills, K. W. ATWATER
Water-Lubricated Soft-Rubber Bearings, W. F. BUSSE and W. H. DENTON
Application of Celoron Bearings to Roll Necks, ARTHUR J. SCHMITT
Application of Tapered Roller Bearings in Merchant-Bar Mills, S. M. WECKSTEIN

AERONAUTICS

(Auspices of Aeronautic Division with cooperation of American Institute of Physics)

A Study of Light Signals in Aviation and Navigation, I. LANGMUIR and W. F. WESTENDORP
Design Problems of Controllable-Pitch Propellers, W. B. HEINZ
Discussion of Aeronautic Progress
Progress Report of Aeronautic Division, presented by ELMER A. SPERRY, Jr.

Thursday Afternoon, December 3

BOILER-FEEDWATER STUDIES

(Auspices of Joint Research Committee on Boiler-Feedwater Studies)

Determination of Carbonate Hydroxide and Phosphate in Boiler Waters (Progress Report of Subcommittee No. 8), W. C. SCHROEDER and C. H. FELLOWS
Foaming and Priming of Boiler Water, C. W. FOULK
The SO_4/CO_3 Ratio for the Prevention of Sulphate Boiler Scale, EVERETT P. PARTRIDGE, W. C. SCHROEDER, and R. C. ADAMS, JR.

OIL AND GAS POWER

(Auspices of Oil and Gas Power Division)

Progress Report of Oil and Gas Power Division, L. R. FORD
Presentation of the Rudolph Diesel Award for Best Paper Delivered at Oil and Gas Power National Meeting, 1931, to K. J. DE JUHASZ
Small Marine-Diesel Installations, L. B. JACKSON
United States Navy Diesel-Engine Requirements, HOLBROOK GIBSON

METAL ROLLING

(Auspices of Iron and Steel Division)

Recent Developments in Merchant-Bar Mills, G. L. FISK
Progress Report of Iron and Steel Division, presented by LEON CAMMEN
Foreign Supplement to Progress Report, presented by W. TRINKS

EDUCATION AND TRAINING

(Auspices of Committee on Education and Training for the Industries and Management Division)

Opening Address, ERIK OBERG, representing PRESIDENT ROY V WRIGHT
Foremanship Training, U. J. LUPIEN
Modern Industrial Training, GEORGE A. SEYLER

Meetings of the Professional Divisions

Aeronautic Division

BALTIMORE, MD., MAY 12–14, 1931

The Fifth National Technical Meeting of the Aeronautic Division was reported in the *A.S.M.E. News* of May 22, 1931. This meeting was held under the auspices of the Baltimore Section of the A.S.M.E., the Engineers Club of Baltimore, and local sections of the American Chemical Society, American Institute of Architects, American Institute of Chemical Engineers, American Society for Steel Treating, Illuminating Engineering Society, A.I.E.E., and A.S.C.E. Structural parts of different planes, models, and other exhibits were arranged by the A.S.M.E. Student Branch of Johns Hopkins University under the direction of W. H. Miller. The Merrill self-landing airplane was demonstrated at the Curtiss-Wright Airport, where the Wednesday afternoon sessions were held. Wednesday morning was devoted to inspection trips, which included the plants of the Glenn Martin Company, B-J Aircraft Company, Friez Instrument Company, and others. A harbor boat trip was arranged for Tuesday afternoon, and the ladies program included other sightseeing trips. The principal speakers at the banquet were Senator Hiram Bingham, president of the National Aeronautic Association, and Admiral W. A. Moffett, head of the Bureau of Aeronautics. The following technical sessions were held.

Tuesday Morning, May 12

OPERATION

An Analysis of Various Airplane Types for Transport Uses, F. T. COURTNEY
Maintenance of Equipment in Air Transport Operation, LESTER D. SEYMOUR
Aircraft Servicing Problems, CHARLES FROESCH

DESIGN

Design and Possibilities of the Light Airplane, J. HENRY REISNER
Airplane Design in Relation to Tactical Requirements, TEMPLE N. JOYCE
Weight Control in Airplane Design, WM. P. MCKINNIE

ENGINES (1)

Analysis of Aircraft Engine Design, HAROLD CAMINEZ
Development of Engines for Light Airplanes, HENRY LOWE BROWNBACK
Light Aircraft Engines and Their Progress, OTTO E. SZEKELY
Two Cycle Aircraft Engine, J. H. GEISSE

Tuesday Afternoon, May 12

AIRPORTS AND MANAGEMENT

Airports for Small Cities, E. L. WHELESS
Engineering Essentials of Airport Enclosures, FREDERICK SCHAUSS
Architectural Principles Applied to Airport Planning, H. V. WALSH
Actual Cost of Operating a Business Airplane, JEROME LEDERER

CONSTRUCTION AND MATERIALS

Special Methods of Testing Aircraft Materials, D. M. WARNER
Plywood in Aircraft, GEO. L. FISCHER
Types of Design and Their Effect on the Structural Design of Airplanes, F. S. HUBBARD

ENGINES (2)

Altitude Laboratory Tests of Aircraft Engines, H. K. CUMMINGS and E. A. GARLOCK
Aircraft Engine Testing and Testing Laboratories, R. N. DUBOIS
Junkers Aero Diesel Engine Type FO-4, by Junkers Research Institute, Germany, presented by CAPTAIN KENNEDY

Tuesday Evening, May 12

The Aviation Lessons of the Byrd Antarctic Expedition, BERNT BALCHEN

Wednesday Afternoon, May 13

METAL

Construction of the Metal Airplane, GEO. H. PRUDDEN
Some Effects of Corrosion-Fatigue on Streamline Wire of Aircraft, H. E. HAVEN
The Cause and Prevention of Heat Cracks in Aircraft Welding, H. S. GEORGE

PROPELLERS

Racing Propellers for Light Airplanes, FRED. E. WEICK
Magnesium and Hollow Steel Propellers, G. T. LAMPTON
The Value of Controllable Pitch Propellers, W. B. HEINZ
Controllable Pitch Propellers, FRANK W. CALDWELL

TRAINING AND NAVIGATION

Vocational Training in Aviation, FRANK CUSHMAN
Modern Flight Training, W. D. TIPTON
The Aviation Course at the U. S. Naval Academy, D. C. RAMSEY
The Ice Hazard on Airplanes, WILLIAM C. GEER

Thursday Morning, May 14

AERODYNAMIC

Control at Low Speed, CARL HARPER
A Study of Stabilizer Beam Loadings in a Dive and During a Sudden Pull-Up, W. H. MILLER
Tail Spinning of Aircraft, G. G. BUDWIG
Decrease of Disturbed Motion in the Flight of an Airplane, LOUIS BREGUET, presented by A. KLEMIN

ENGINES (3)

Wing Radiator Development, G. A. LUBURG
Engine Ring Cowls, W. H. EVERS
Engine Ring Cowls, PAUL M. BOYD
Observations on the Development of the English High Speed Oil Engines From Submarine to Airship R-101, ALAN E. L. CHORLTON, presented by E. T. VINCENT

INSTRUMENT

Instrument Flying and Its Teaching, W. C. OCKER and CARL J. CRANE
Performance of Aneroid Altimeters for Landing and for Level Flying, W. G. BROMBACHER
The Sonic Altimeter, C. W. RICE
The Directional Gyro, E. A. SPERRY, JR.

Thursday Afternoon, May 14

COMMUNICATION

Radio Methods for Flying and Landing Airplanes in Fog, H. DIAMOND and F. W. DUNMORE
Transmission of Visible Infra-Red and Ultraviolet Radiations Through Fog With Reference to Developing Aids and Fog Flying, S. HERBERT ANDERSON
Effect of Lightning on Airplanes, A. O. AUSTIN
Discussion on Airways Communication, EUGENE SIBLEY, GEO. G. BREED, H. A. ELLIOTT, H. N. WILLETS

AIRSHIPS

The Mooring and Ground Handling of a Rigid Airship, C. E. ROSENDAHL
Water Recovery Apparatus for Airships, CHARLES P. BURGESS
Stresses in Rigid Airships; The Effect of Indeterminateness on Their True Value, W. WATTERS PAGON
Pressure in Airships, W. A. KLIKOFF

GENERAL DESIGN

The S-Rotor, S. SAVONIUS
Single Blade Windmill for Electric Generation, E. N. FALES
The Autogiro Rotor, HERACLIO ALFARO
Supercharging the Engine and Increasing the Speed With Altitude, ROBERT J. NEBESAR
Aerodynamics and Structural Aspects of the Merrill Biplane, JOHN BALLOU

Applied Mechanics Division

LAFAYETTE, IND., JUNE 15–17, 1931

The *A.S.M.E. News* for July 7, 1931, contains an account of the First National Meeting of the Applied Mechanics Division, held at Purdue University, preceding the annual meeting of the Society for the Promotion of Engineering Education. About 170 were registered for the meeting. An exhibit of special research apparatus was held in conjunction with the meeting and included sound-deadening devices, vibration-recording apparatus, small fatigue machines, tensile-testing machines, etc. At a dinner meeting on June 15 speeches were made by J. M. Lessells on "The Growth of the Division," by C. R. Soderberg on "The Engineer of Today," and by Dr. S. Timoshenko on "Teaching of Mechanics at the University of Michigan," and Dr. Bakhmeteff, of Columbia University, spoke briefly on "Hydraulics." There were four technical sessions, the papers for which were as follows:

Monday Morning, June 15

STRESS ANALYSIS

Spiral Springs, J. A. VAN DER BROEK
Recent Advances in Photo-Elasticity and an Investigation of the Stress Distribution in Square Blocks Subjected to Diagonal Compression, MAX M. FROCHT
The Flexibility of Corrugated Pipes Under Longitudinal Forces and Bending, L. H. DONNELL
The Strength of Thin Plates in Compression, T. VON KARMAN, ERNEST E. SECHLER, and L. H. DONNELL

Monday Afternoon, June 15

STRESS ANALYSIS AND PLASTICITY

Thermal Stresses in Thin-Walled Cylinders, CLARENCE H. KENT
Strength of Materials Subjected to Shear at High Temperatures, FRANKLIN L. EVERETT
Flow of Steels at Elevated Temperatures, F. P. COFFIN and T. H. SWISHER
Concerning the Yield Point of Mild Steel, C. W. MACGREGOR
The Center of Torsion for Angle and Channel Selections, W. L. SCHWALBE (presented by title)

Tuesday Morning, June 16

VIBRATION

A New Type of Dynamic Balancing Machine, ERNEST L. THEARLE
Noise Prevention Through Elastic Suspension, E. H. HULL
The Sub-Critical Speeds of the Rotating Shaft, C. RICHARD SODERBERG
Forced Vibration With Combined Coulomb and Viscous Friction, J. P. DEN HARTOG

Tuesday Afternoon, June 16

HYDRODYNAMICS

Propeller Type Fan, O. G. TIETJENS
The Hydraulic Jump and Related Phenomena, BORIS A. BAKHMETEFF
The Boundary Layer and Skin Friction for a Figure of Revolution, CLARK B. MILLIKAN
Jets From Manifold Tubes, JAKOB KUNZ

Fuels Division

CHICAGO, ILL., FEBRUARY 10–13, 1931

The Fourth National Meeting of the Fuels Division was held in conjunction with the Fifth Midwest Power Engineering Conference and the Fifth Midwest Power Exposition. It was reported in the February 22, 1931, issue of the *A.S.M.E. News*.

More than 1000 engineers attended these events. At a joint banquet on February 12 O. H. Caldwell, editor of *Electronics*, delivered an address on "The Electron, Midget Ruler of the Universe," and H. B. Stevens, of the Westinghouse Elec. & Mfg. Co., demonstrated a number of electron tube devices.

Wednesday Afternoon, February 11

Use of Refinery Waste Fuels in Modern Steam Plants, H. J. KLOTZ
The Economics of Fuel Utilization, A. L. BROWN
New Processes of Dehydrating Low-Grade Coal, MAX TOLTZ

Wednesday Evening, February 11

Symposium on Small Stokers, T. A. MARSH
Utilization of Anthracite Coal, C. A. CONNELL
Conversion of Coal-Fired Boilers and Furnaces to Gas Firing, W. D. EDWARDS

Thursday Morning, February 12

Slag Tap Furnaces, A. L. BAKER
Developments in Pulverized-Fuel Firing, H. KREISINGER

Thursday Noon, February 12

LUNCHEON MEETING

Recent Developments in Bituminous-Coal By-Products, A. C. FIELDNER

Thursday Afternoon, February 12

Effect of Fineness of Pulverization on Boiler Efficiencies, E. H. TENNEY
Radiation in Boiler Furnaces, N. ARTSAY
Reduction of Unaccounted for Losses in Boiler Tests, W. F. DAVIDSON

Friday Morning, February 13

Selection of Steam Generating Equipment, F. H. ROSENCRANTS
The Pioneering Element in the Boiler Plant of the Future, GEO. A. ORROK
Changes in Character of Mid-West Coals and Stoker Performance, E. L. MCDONALD

Friday Afternoon, February 13

The Fly Ash Problem, H. N. BUBAR
Round Table Discussion of "Air Pollution Problems," led by ELLIOTT H. WHITLOCK and ELY C. HUTCHINSON

Iron and Steel and Machine Shop Practice Divisions

BOSTON, MASS., SEPTEMBER 22, 1931

A joint meeting of the Iron and Steel and Machine Shop Practice Divisions was held under the auspices of the Boston Section during the National Metal Congress, in which the A.I.M.E., A.S.S.T., S.A.E., and A.W.S. also cooperated. The excursion to the Watertown Arsenal on the morning of September 22 was participated in by about 200. Simultaneously the Iron and Steel Division joined with the A.S.S.T. in a session on sheet steel, at which the following papers were presented.

The Evaluation of the Drawing Quality of Extra Deep Drawing Sheets, THOMAS DOCKRAY
Thin Strip Steel for Deep Drawing, H. T. MORTON and I. A. RUMMLER
Some Effects of the Amount and Rate of Deformation on a Low Carbon Strip Steel, JOSEPH WINLOCK and A. E. LAVERGNE
Effect of Normalizing Upon the Grain Structure and Physical Properties of Automobile Sheet Steel, WM. F. MCGARRITY
Plastic Drawing of Sheet Steel Into Shapes, E. V. CRANE
Lubricants Used in Deep Drawing of Sheet Steel, MAURICE REDWICK
Comparison of Sheet and Strip Steels for Difficult Stampings, EDW. S. LAWRENCE

At a session of the Machine Shop Practice Division in the afternoon three papers were presented, as follows:

Belt Drives With Cast-Iron Pulleys and Paper Pulleys, C. A. NORMAN and G. N. MOFFATT
Positive Drive Equipment, C. R. WEISS
Radiographic Inspection of Steel Castings and Welded Structures, HERBERT R. ISENBURGER

At this session two films were shown, one on the latest developments in German machine tools as exhibited in operation at the Leipzig Trade Fair and the other from the Research Laboratories of the Westinghouse Elec. & Mfg. Co. on gear research studies. A group conference on coordination of research on wear of metal resulted in a unanimous vote to ask the A.S.M.E. to consider the establishment of a committee to act as a clearing house for the research work being done on wear of metals with the possibility of establishing some general principles.

M-M-M Congress

CLEVELAND, OHIO, APRIL 13–17, 1931

The Management and Materials Handling Divisions and the Elimination of Waste Committee of the A.S.M.E. participated in the National Industrial Congress, the local arrangements for which were under the auspices of the Cleveland sections of the A.S.M.E. and S.I.E., the Cleveland Engineering Society, and the Cleveland Handling Equipment Manufacturers Committee and Chamber of Commerce. Other participants were the Society of Industrial Engineers, American Management Association, and Cleveland Electrical Maintenance Engineers Association. An account of the congress will be found in the *A.S.M.E. News* for May 7, 1931.

In addition to the program of technical sessions given herewith, there was a joint banquet at which Newton D. Baker introduced one of the principal speakers of the evening, General G. G Harbord, who spoke on "What the Future Can Expect From Radio." Dr. Lillian Gilbreth was the second speaker; her address dealt with the machine age and its relation to the development of skill

Inspection trips were made to the Westinghouse Elec. & Mfg. Co., the Willard Storage Battery Co., the Hupp Motor Car Co., Lamson & Sessions Co., the Midland Steel Company, American Steel & Wire Co., and the White Motor Company.

The Second National Industrial Exposition paralleled the congress and included a number of exhibits by the Elimination of Waste Committee.

The maintenance engineering sessions were arranged by the Management Division of the A.S.M.E. and the Materials Handling sessions were arranged by the Materials Handling Division.

Monday Afternoon, April 13

SCRAP HANDLING

(Auspices Elimination of Waste Committee, A.S.M.E. and A.M.A.)

Handling of Thin Sheet Scrap in Tin Plate and Sheet Steel Mills, H. H. GILES
Handling of Automobile Body Scrap, R. R. REES
Briquetting of Cast-Iron Borings and Steel Turnings, A. K. NOWAK
Discussion of Handling and Disposition of Ferrous Scrap

Monday Evening, April 13

WASTE ELIMINATION

(Auspices Elimination of Waste Committee, A.S.M.E. and A.M.A.)

Segregation and Control of Waste, C. H. MCKNIGHT
Waste Campaign Experiences and Suggestion Systems. (Short talks giving experiences from several companies.)
A Plant Museum and Its Relation to Plant Control in the Ceramic Industry, W. A. WELDON

Tuesday Afternoon, April 14

MANAGEMENT

(Auspices Management Division, A.S.M.E.—A.M.A. cooperating)

Developments in Manufacture of Lead-Covered Paper-Insulated Telephone Cables, J. R. SHEA
Planning a Lead-Covered Telephone Cable Manufacturing Plant, L. C. HANLEY

HOISTS AND MONORAIL HANDLING

Monorail Handling of Materials, C. W. PRESTON
Engineering Factors in the Use of Electric Hoists, H. J. FULLER
Use of Monorails, A. A. BUREAU and J. R. HOOPER

Tuesday Evening, April 14

DRAFTING ROOM MANAGEMENT

(Auspices Management Division, A.S.M.E.—A.M.A. cooperating)

Production Management Applied to the Drafting Department, W. J. KUNZ
Improved Drafting Room Management, F. D. NEWBURY

Wednesday Afternoon, April 15

CONVEYOR HANDLING

Synchronization of Production Control With Conveyorization, E. M. OLIN and W. C. BEATTIE
Materials Handling in Mass Production at General Electric Plant, H. C. RUNDLE

OUTDOOR HANDLING

Remote Controlled A.C. Haulage at the Plant of the Trinity Portland Cement Company, R. F. EMERSON
Automatic Electric Transfer Cars, E. W. SHELLENTRAGER
Industrial Type of Internal-Combustion Engine Locomotive, S. B. SCHENCK

Wednesday Evening, April 15

DESIGN HANDLING EQUIPMENT

Application of Two-Speed Motors to Monorail Electric Hoists, C. E. SCHIRMER
Variable-Speed Transmission for Materials Handling, D. W. CLEM
Types of Materials Used in Materials Handling Equipment, HERVEY SKINNER

MANAGEMENT

(Auspices Society of Industrial Engineers)

Skill and Satisfaction, LILLIAN GILBRETH

TRUCKING AND SHIPPING

Skids and Skid Shipments, R. L. LOCKWOOD
Use in Marine Terminals, H. E. STOCKER
Use in Railroad Terminals and Stores, J. B. MILLER
Materials Handling of Platforms, C. C. STUBER
The Use of Gas Trucks and Tractors in Materials Handling, GEO. E. HAGEMANN

Thursday Morning, April 16

ORGANIZATION SESSION FOR MAINTENANCE ENGINEERS

Variations in Maintenance Costs and Procedure, E. B. STOODY and G. I. ROSS
Departmental Analyses and Wage Incentives, W. G. UHLIR
The Control of Non-Productive Costs, HARRY W. BENTON
Organization and Operation of the Electrical Maintenance, SIDNEY WATKINS

MATERIALS HANDLING

Automatic Electric Control of Materials Handling, J. E. WOOD
Pneumatic Handling of Vegetable Potash, J. F. BARNARD
Handling Small Packages in the Shop, C. A. FIKE

Thursday Afternoon, April 16

OPERATING SESSION FOR MAINTENANCE ENGINEERS

Maintenance of Electric Cranes and Hoists, ROBT. W. WALTON
Tools for the Maintenance Engineering Department, T. A. KEEFER
Inspection for Preventative Maintenance, A. HECKMAN

MATERIALS HANDLING

Use of Rubber Products for Materials Handling, CHAS W. STAACKE
Weighing and Counting Devices Used With Material Handling Equipment, A. B. JACOBUS

Friday Afternoon, April 17

HOUSEKEEPING SESSION FOR MAINTENANCE ENGINEERS

Maintenance of an Industrial Illumination System, R. C. SMITH
Maintaining the Lighting System, WALTER STURROCK
Maintenance Painting, T. J. MALONEY

MATERIALS HANDLING

Handling Bulk Materials Mechanically, W. W. SAYERS
Uses and Application of Portable Conveyors, J. B. BRAY

Oil and Gas Power Division

MADISON, WIS., JUNE 23–26, 1931

The Fourth National Meeting of the Oil and Gas Power Division held at the University of Wisconsin with a registration of more than 250, was reported in the *A.S.M.E. News* for July 7, 1931. The laboratory of the new mechanical engineering building, which was dedicated on June 22, provided excellent facilities for the exhibit of Diesel engines and equipment. An informal gathering, with entertainment and dancing, on the first evening of the meeting, and a banquet at which Professor Louis Kahlenberg, of the Chemistry Department of the university, was the principal speaker, on Thursday evening, were the chief social events. Thursday was largely devoted to an inspection trip to the works of Fairbanks, Morse & Co. A number of special events for the ladies were provided. The program of technical papers follows:

Tuesday Afternoon, June 23

Dispersion of Oil Sprays, K. J. DEJUHASZ
A Quiescent Combustion Chamber, JOHN A. SPANOGLE
Experiments on the Flow of Air Through Engine Valves, E. S. DENNISON and T. C. KERCHLEE

Wednesday Morning, June 24

Report of Diesel Fuel Research Committee, presented by WILEY BUTLER
Report of Diesel Power Committee, presented by M. J. REED
How to Select a Diesel Engine, OTTO NONNENBRUCH
Development of a High-Speed L-Head Diesel Engine, MAX HOFMANN

Wednesday Afternoon, June 24

Development of Double-Acting Diesels, LOUIS R. FORD
Present Position of the Automatic Diesel-Electric Plant, EDGAR J. KATES
Diesel Municipal Light Plants in the Middle West, C. F. LAMBERT

Wednesday Evening, June 24

Observation of European Diesel Developments, JOHN O. HUSE
European Trends in Diesel Design, O. F. ALLEN
Diesels for Motor Trucks, contributed by Verein deutscher Ingenieure

Thursday Morning, June 25

Application of Oil Engines to Ship Propulsion, A. J. C. ROBERTSON
Light Alloy Pistons and Rods in High-Speed Industrial Engines, B. J. ISIDIN

Friday Morning, June 26

Piston Packing Problems, C. K. SENCEBAUGH
An Outstanding Municipal Diesel Power Plant, CLEMENT RUEGG
Heat Recovery From Internal-Combustion Engines, THOMAS CLARKSON and WILLIAM BRADFORD

Petroleum Refining Meeting

ELIZABETH, N.J., MAY 5–6, 1931

The meeting of the Refining Committee of the Petroleum Division under the auspices of the Plainfield Section was attended by nearly 300 members and guests. An account of it will be found in the *A.S.M.E. News* for May 22, 1931. At a dinner on the evening of May 5 Dr. P. K. Frolich, of the Standard Oil Development Company, spoke on "Chemistry and Mechanical Engineering," and there was an illustrated talk on oil developments in Russia. The discussion at the Tuesday afternoon session resulted in a unanimous vote to request the Refining Committee to appoint a committee made up of representatives of oil refiners and heat-exchange-equipment manufacturers to study the question of a test code. The meeting closed on Wednesday afternoon with an inspection trip to the Bayonne plant of the Standard Oil Company of New Jersey. Papers presented at the technical sessions were as follows:

Tuesday Morning, May 5

Centrifugal Dewaxing of Vacuum Distilled Overhead Lubricating Stocks, MAX B. MILLER
Distillation of Topped Crude Under Vacuum for the Recovery of Lubrication Oil Distillates, C. E. MCCULLOUGH and JOHN PRIMROSE

Tuesday Afternoon, May 5

Suggested Specifications for Testing Tubular Heat Transfer Equipment for Oil Refineries, prepared by Atlantic Refining Company, presented by WALTER SAMANS
Discussion of Problems of High Pressure and Temperature Oil Refining

Wednesday Morning, May 6

The Evolution of Pressure Vessels to Meet Present Day Refining Pressures and Temperatures, H. LEROY WHITNEY
Forged Drums for Oil Refining, JOHN L. COX
Welded Vessels for Oil Refining, T. MCLEAN JASPER
New Development of Chromium Tungsten Steel for Oil Refining Service, V. T. MALCOLM
Discussion on Metal Problems in Oil Refining

Lubrication Engineering Meeting

STATE COLLEGE, PA., MAY 22, 1931

About 125 attended the joint meeting of the Lubrication Engineering Committee of the Petroleum Division with The Pennsylvania State College, during the Fifth Oil Power Conference of the College. At a lubrication research session in the morning the following papers were presented:

Lubricating Testing, E. G. BODEN and O. L. MAAG
Bearing Design in the Light of Oil Film Pressure Investigations, L. J. BRADFORD
Fluid Film Lubrication as Applied to Railroad Journal Bearings, F. O. WILLHOFFT
Oral Discussion of Lubrication of Railway Bearings, M. E. MCDONNELL

A symposium on internal-combustion engine lubrication was held in the afternoon, with papers discussing lubricants from coastal crudes by A. Ludlow Clayden, Pennsylvania crudes by C. M. Larson, and Midcontinent crudes by E. R. Lederer. The meeting was reported in the *A.S.M.E. News* for June 7, 1931.

Printing Industries Division

WASHINGTON, D.C., MARCH 16–17, 1931

The Second Conference of Technical Experts in the Printing Industry was attended by about 500 delegates. The Government Printing Office and the United Typothetae of America were joint hosts for the meeting. The *A.S.M.E. News* for April 7, 1931, presents a report of the conference. In addition to the program of technical papers presented here, there were group conferences on air-conditioning data, establishing color standards for printing, and the standardization of paper, thickness of plates, patent bases, and cylinder diameters. The various departments of the Government Printing Office and its new research laboratory were open for inspection, and there were special demonstrations of printing machinery and other exhibits. Takeo Ohara, connected with the two Japanese newspapers, "Osaka Mainichi" and "Tokyo Nichi-Nichi," was the principal speaker at a dinner meeting, his subject being "The Great Newspapers of Japan: Their Circulations and Equipment." There were four technical sessions, as follows:

Monday Morning, March 16

Air Conditioning for Printing, WILLIS H. CARRIER
Paper Pulp From Hybrid Poplars, a Reforestation Remedy, RALPH H. MCKEE

Monday Afternoon, March 16

Premakeready Methods and Machines, J. W. ROCKEFELLER, JR.
Paper and Ink Testing—Some Simple Tests and Their Application; Some Troubles and the Remedy, SUMMERFIELD ENEY, JR.
Ink Drying by Ozone and the Ultraviolet Ray, ROBERT A. BROWN

Tuesday Morning, March 17

Electrotype Versus Stereotype Printing Plates, WILLIAM T. TIMMONS
The Mechanics of Photoengraving, WILLIAM GAMBLE
Chromium Plating of Plates and Slugs: Their Life and the Advantages, GEORGE B. DRACH and A. WEISBURG

Tuesday Afternoon, March 17

Measuring Color and the Use of the Spectrophotometer in Determining and Matching Shades, P. J. MULDER and JOSEPH RAZEK
The Renck Process, FRIEDRICH SACHS
Ink Misting, ARTHUR THOMPSON
The Effect of Rubber Rollers, BERT REED

Textile Division

PROVIDENCE, R.I., OCTOBER 6, 1931

The New England Meeting of the Textile Division was held jointly with the Providence Section and is reported in the October 22, 1931, issue of the *A.S.M.E. News*. Inspection trips to the Cranston Point Works, the Universal Winding Company, and the Crompton & Knowles Loom Works were arranged for the afternoon. An informal dinner was followed by an evening session at which the following papers were presented.

United Quality and Economy in the Fabrication of Textiles, A. I. HARVEY
Development in Gaseous Fuels for Textiles and a New Singeing Application, R. S. VAN NOTE

The meeting was attended by about 80 members and guests.

Wood Industries Division

WINSTON-SALEM, N.C., OCTOBER 15–16, 1931

The Sixth National Wood Industries Meeting, held under the auspices of the Charlotte and Raleigh Sections, with the cooperation of the Southern Furniture Manufacturers' Association, was

reported in the *A.S.M.E. News* for October 22, 1931. Inspection trips to the B. F. Huntley Furniture plant and the Winston-Salem Chair Company, which opened the meeting, were followed by a luncheon meeting at which Fred Tate, president of the Continental Furniture Company, High Point, N.C., talked on the "Growth of the Furniture and Panel Industry in the South." The second morning was also devoted to inspection trips, visits being made to plants of the Myrtle Desk Company, High Point Furniture Company, Thomasville Chair Company, K. & L. Panel Co., and Kennedy Plywood Company. A feature of the meeting was an exhibit to which educational charts and panels were contributed by the National Committee on Wood Utilization of the Department of Commerce, the Government Forest Products Laboratory of Madison, Wis., Iowa State College, the Bureau of Standards, and a number of companies. The program of the technical sessions follows.

Thursday Afternoon, October 15

MANUFACTURING

The Essentials of Securing Maximum Kiln Efficiency, KENNETH REDMAN
Dimension Stock Manufacture, Its Theory and Economy, D. B. MORGAN
Manufacture of Plywoods and Panels Made With Veneer Cores, N. M. LEWIS
Developing a New Wood Product Through Research, THOMAS D. PERRY

Thursday Evening, October 15

MACHINE AND EQUIPMENT

Types of Hydraulic Presses in Wood Gluing Processes, H. G. FRANCIS
Double End Tenoner and Its Use, JUDSON H. MANSFIELD
Modern Methods Used in Dust-Collecting Systems, H. A. COLVIN
Studies in Design of Local Exhaust Hoods, J. DALLAVILLE and T. HATCH

Friday Afternoon, October 16

SYMPOSIUM ON GLUES FOR WOOD PRODUCTS

The Development of Wood Adhesives and Gluing Technic, T. R. TRUAX
Vegetable and Starch Glues, A. B. MAINE
Oil Seed Residue Glues, I. F. LAUCKS and GLENN DAVIDSON
Casein Glues, W. F. LEICESTER
Animal Glues, WILBUR L. JONES
Blood Albumen Glues, C. P. SMITH

Friday Evening, October 16

DRYING AND FINISHING

How Dry Should Wood Be for Various Industrial Uses? H. L. HENDERSON
Some Observations on Raised Grain, ARTHUR KOEHLER
Comparative Tests on Aluminum Oxide Versus Garnet Paper as Wood Abrasive, J. F. TRAENDLY
Study in Present-Day Wood Finishing, H. A. DERR

Necrology

EDWARD GOODRICH ACHESON

Edward Goodrich Acheson, whose death occurred on July 6, 1931, was born at Washington, Pa., on March 9, 1856, the son of William and Sarah D. (Rupl6) Acheson. At the age of sixteen he was obliged to terminate his studies at the academy at Bellefonte, Pa., because of financial losses suffered by his father. He became time-keeper at his father's blast furnace at Monticello, Pa., and devoted his leisure time to mechanical pursuits which resulted in the invention of a rock-boring machine, for which he filed his first application for a United States patent at the age of seventeen. His father died in 1873 and the furnace was closed the following year. Mr. Acheson was variously employed during the next six years as a dry-goods clerk, surveyor, ticket clerk, and tank gager in the oil fields at Bradford, where he developed a set of tables for easily determining the contents of any tank.

In 1880 Mr. Acheson became interested in the electrical industry and secured employment as an assistant draftsman for Thomas A. Edison at Menlo Park. The following year he received a prize of $100 offered by Mr. Edison for the preparation of a graphite loop or filament, and was appointed first assistant to the chief engineer in charge of the Edison exhibit at the International Exposition in Paris. At the close of the exposition Mr. Acheson aided in the construction of power units and lamp factories at Ivry-sur-Seine for the Société Edison Continentale of Paris, and later installed the first electric lighting systems at Milan, Antwerp, Amsterdam, and Brussels.

After two and one-half years in Europe, Mr. Acheson returned to New York. He left the Edison interests shortly afterward to take a position as superintendent of the Consolidated Lamp Company, Brooklyn, a lamp factory working under the Sawyer-Man patents. He also conducted experiments on the problem of direct conversion of heat into electrical energy and the production of insulated wire. He invented an anti-induction telephone cable in 1886 and attempted to reduce iron ore with natural gas and to produce synthetic rubber. He was electrical engineer for the Standard Underground Cable Company of Pittsburgh from 1886 to 1889.

In 1890 Mr. Acheson founded the Monongahela Electric Light Company. With the high temperatures obtainable electrically there he conducted experiments upon clay-carbon mixtures which resulted in the production of silicon carbide ("carborundum"). The Carborundum Company was formed at Monongahela in 1891, moving four years later to Niagara Falls, where cheaper power was available.

Mr. Acheson next experimented with silicon carbide and found that when subjected to high temperatures it decomposed, leaving a residue of graphitic carbon of high purity. This first product was put on the market in 1899 by the Acheson Graphite Company, which was later known as the International Graphite Company and then the Acheson Graphite Corporation of Niagara Falls.

Graphite, in its turn, led Mr. Acheson to another development. In 1901, while endeavoring to use graphite in crucible manufacture, he tried clay as a binder. He discovered a method of improving the plasticity of clays which, when applied to graphite five years later, led to the production of colloidal-graphited oil and colloidal-graphited water. The Acheson Oildag Company, Port Huron, Mich., was organized in 1908 to manufacture these products under their trade names of "oildag" and "aquadag," respectively.

Another product developed by Mr. Acheson, in 1902, was a chemical compound by electrothermic means which he named siloxicon, a refractory material.

His later years were devoted to finding new uses for his products. The firm of E. G. Acheson, Ltd., was established in England in 1911 to cover the demand for colloidal graphite products in Europe. The Acheson Ink Company was incorporated in 1915 for the production of high quality inks by the deflocculating process. The Acheson Corporation and the Goodrich Corporation were formed in 1915 and 1925, respectively, to coordinate Mr. Acheson's various interests and activities.

Mr. Acheson was the recipient of many honors, including the John Scott Medal by the City of Philadelphia, in 1894 for the production of silicon carbide and in 1901 for the production of artificial graphite; the Count Rumford Medal by the American Academy of Arts and Sciences; the Perkin Medal by the American Section of the Society of Chemical Industry; and the first award under the Edward Goodrich Acheson Fund which he established in 1928 under the control of the American Electrochemical Society. The degree of Doctor of Science was conferred upon him in 1909 by the University of Pittsburgh.

Among the engineering and scientific societies to which Mr. Acheson belonged were the American Institute of Electrical Engineers, Franklin Institute, Society of Arts (London), American Institute of Chemical Engineers, of which he had been a vice-president, American Chemical Society, Society of Chemical Industry, American Ceramic Society, and the A.S.M.E., which he joined in 1918. He was a fellow of the American Association for the Advancement of Science, past-president of the American Electrochemical Society, and an honorary member of the Russian Imperial Technical Society and the Swedish Technical Society.

Mr. Acheson is survived by his widow, Margaret (Maher) Acheson, whom he married in 1884, and by four sons and three married daughters.

EDWIN HUGH AHARA

Edwin Hugh Ahara, who retired from active business in 1923, died of heart trouble in London on June 22, 1931. He is survived by his widow, Emma Josephine (Bigelow) Ahara of Mishawaka, Ind., whom he married in 1897, and by one married daughter. Mr. Ahara was born on January 6, 1865, at Evansville, Wis., the son of Hugh and Mary Jane (Leighton) Ahara. He attended the seminary in Evansville and then entered the University of Wisconsin, from which he received a B.S. degree in civil engineering in 1892 and an M.E. degree four years later. His first position was with the Eclipse Manufacturing Company, Beloit, Wis., where he did general machine-shop work before the completion of his college education. He was also superintendent in 1893–1894 for the Esterly Harvester Company, Minneapolis, Minn., and for a time transit operator on the Upper Mississippi for the United States Government. From 1895 to 1902 he was in charge of tools and mechanical equipment for the Deering Harvester Company, Chicago. From then until his retirement he was associated with the Dodge Manufacturing Company, later known as the Dodge Manufacturing Corporation, of Mishawaka, Ind., serving successively as manager of the manufacturing department, general superintendent, and manager of manufacturing for the corporation.

Mr. Ahara became a member of the A.S.M.E. in 1906. He served as president of the Indiana Engineering Society in 1915 and was president in 1931 of the St. Joseph Valley Society of Engineers. He was an active member of the Masonic fraternity and a member of several clubs in South Bend and Mishawaka. He was captain of the Wisconsin football team while at the University and retained a keen interest in football and other sports. He was also active in civic affairs, being a member of the Mishawaka Chamber of Commerce and of the Mishawaka School Board, on which he had served as secretary and president. In 1915 he was a member of the Mishawaka Public Library Commission. He held United States patents for driving clutches and guards and for sheet metal hangers. As a result of extensive tests extending over many months at the Dodge plant, he presented a paper at the 1913 Annual Meeting of the A.S.M.E. on "Efficiency of Rope Driving as a Means of Power Transmission."

CHARLES DAVIES ALLAN

Charles Davies Allan, of Chicago, Ill., died in that city on January 25, 1930. He was born at Fishkill-on-the-Hudson (now Beacon), N.Y., on March 29, 1868, the son of Dr. George Allan. His technical education was secured at Cornell University, where he took a three-year course in mechanical engineering. After leaving Cornell in the spring of 1893, Mr. Allan spent about twenty years in construction and sales work for different companies, for the most part in New England and New York, and during the remainder of his life engaged in consulting work in the design of heating, ventilating, and power plants.

The companies with which Mr. Allan was connected included the Buffalo (N.Y.) Forge Company, American Stoker Company, New York, N.Y. (no longer in business), B. F. Sturtevant Co., Boston, Mass., American District Steam Company, North Tonawanda, N.Y., Almirall & Co., New York, and General Fire Extinguisher Company, Providence, R.I., for whom he was western manager of the heating and power piping department.

Mr. Allan became a member of the A.S.M.E. in 1917. He also belonged to the American Society of Heating and Ventilating Engineers and served as president of its Illinois chapter in 1923 and 1924. He is survived by his widow, Catherine (Harriman) Allan.

ETHAN EDWARD ALLEN

Ethan Edward Allen, whose death from heart trouble occurred at St. Lukes Hospital, Manila, P.I., on September 10, 1930, was born at Milton, Vt., on July 9, 1867. He was the son of Ethan Edward and Grace Ruth Pearl Allen. He obtained his education at Brigham Academy, Bakersfield, Vt. He served an apprenticeship as a machinist at the Mystic Iron Works, Stanbridge, Quebec, Can., from 1884 to 1889. During the next two years he was toolmaker for the Hamden Watch Company, Springfield, Mass., and Canton, Ohio, and then foreman of the machine department of the Danner Manufacturing Company, Canton. He went to Cleveland in 1892 to work as foreman and designer for the St. John's Typeobar Company. Following that he was employed in 1894 and 1895 by the Warner & Swasey Co. of Cleveland. In 1895 and 1896 he was engaged in the manufacture of bicycles as foreman toolmaker for the Eclipse Bicycle Company, Elmira, N.Y., and the Worcester (Mass.) Cycle Company. He next designed dies for the Worcester Sheet Metal Company for a year. In 1897 he went to Salt Lake City, Utah, to accept a position as superintendent of the Keller Balance Manufacturing Company.

From 1898 to 1900 Mr. Allen saw service in the Philippine Islands as a first sergeant, Battery A, Utah Volunteer Artillery. He was chief engineer of a United States gunboat, at Laguna Bay, P.I., for the next two years. He returned to private business as construction engineer for the Manila & Dagupan R.R. Co., Philippine Islands, in 1902. The following year he became chief engineer for the Coast and Geodetic Survey in the Philippine Islands. In 1905 and 1906 he was assistant superintendent and master mechanic of the San Nicholas Iron Works in Manila, and for the next eight years superintendent for Manuel Earnshaw & Co. of that city. He was engineer for the Abaca Products Company of Manila from 1914 to 1917 and for the next year was connected with the Mambulao Placer Company, Mambulao, P.I. From 1918 to 1920 he was employed by the Cooper Company and during the next five years by the North Negros Sugar Company as chief engineer. After a year's vacation he became president and manager of the Moro Improvement & Trading Co., Inc., at Davao, Mindanao, P.I., where he remained until his death.

Mr. Allen became a member of the A.S.M.E. in 1915. He was a life member of the National Rifle Association and belonged to the Manila Rifle Club. He is survived by his widow, Elizabeth (Rahe) Allen, whom he married in 1913.

HARRY BARTLETT ALVERSON

Harry Bartlett Alverson, electrical engineer for the Buffalo General Electric Company, Buffalo, N.Y., died on January 25, 1931. Ill health for about a year had made it impossible for him to do more than serve the company as a consultant.

Mr. Alverson was born at Portage, Wis., on March 27, 1872, the son of Miles Talcott and Melissa (Low) Alverson. He married Corrine Van Buskirk in 1904. Two daughters survive him.

The University of Wisconsin conferred a B.S. degree in electrical engineering upon Mr. Alverson in 1893. During the following year, he engaged in graduate study at Cornell University. The next two years were spent with the White-Crosby Company (later J. G. White Company) of Baltimore, building a conduit system at Baltimore and street railways at New York and in New Jersey, and with the Buffalo & Niagara Falls Electric Ry. in construction work and as shop and repair foreman.

In 1896, Mr. Alverson became superintendent of The Cataract Power & Conduit Co. This company, which was founded in 1896, was a pioneer in central-station work. It handled power transmitted from Niagara Falls, and Mr. Alverson's position required a thorough knowledge of the design of the plants and their equipment. He continued in the capacity of superintendent and electrical engineer for the company until it was merged with the Buffalo General Electric Company in 1915, when he became electrical engineer of the latter company. He was connected with the construction of the first transmission lines between Niagara Falls and Buffalo, and with the underground conduit system in Buffalo. From the Terminal Station near the Buffalo city line, Mr. Alverson supervised the cable system to the then existing stations of the Buffalo General Electric Company, The International Railway Company, and The Cataract Power & Conduit Co., including the design and construction of the terminal stations and substations of the latter company.

Much of the success of the spectacular electrical display and other features of the Pan-American Exposition in 1901 may be attributed to his ability in the handling of the power involved.

In 1908 he also became treasurer of the Hual Construction Company, Inc., builders of underground conduits, sewers, etc.

Mr. Alverson became a member of the A.S.M.E. in 1915. He also belonged to the American Institute of Electrical Engineers and had served for one year as chairman of its Niagara Frontier Section. He was a member of the University Club, the Buffalo Athletic Club, and the Masonic fraternity.

NATHAN BABCOCK AMBLER

Nathan Babcock Ambler, superintendent of the hydroelectric plant at the Wilson Dam, Florence, Ala., died on April 11, 1931.

Mr. Ambler was born at Chatham, N.Y., on May 29, 1876, and attended the Academy there. He was graduated from the School of Applied Science of Columbia University in 1900 with an electrical engineering degree. During the next three years he was employed by the Metropolitan Street Railway Company, New York, N.Y., as wireman and electrical operator and foreman in its railway substation. From 1904 to 1907 he was engaged in the construction and operation of the railway substation for the Westinghouse, Church, Kerr Company, and the Long Island Railway Company. During the next year, he was superintendent in charge of electrical construction work for the Aluminum Company of America and the Westinghouse, Church, Kerr Company. Acting for the Box Board Manufacturing Company, he took charge in 1909 of the operation and development of an oil field in West Virginia. He returned to New York to accept a position as chief draftsman for electrical traction and station construction for the Pennsylvania Tunnel & Terminal Ry. Two years later, in 1912, Messrs. Gibbs & Hill, consulting engineers, New York, employed him as chief draftsman.

Mr. Ambler entered the employ of the Toronto Power Company, Ltd., of Niagara Falls, in 1913 as superintendent of operation and took charge of the construction and operation of the generating and transformer station for the company. Following his resignation from the company in 1924, Mr. Ambler was connected for a short time with McClellan & Junkersfeld, Inc., New York. He had been with the United States Engineering Department at Florence since 1927. Mr. Ambler's membership in the A.S.M.E. began in 1915

PELLE ANDERSSON

Pelle Andersson, who died on January 10, 1931, was born at Kellstorp, Sweden, on October 9, 1866. He was educated at the Malmo Technical Institute, Sweden, and did engineering work in that country until 1892. In that year he came to the United States and secured employment as a draftsman for the Chase Elevator & Manton Windlass Co. at Warren, R.I. After two years with this company, he went to Philadelphia, Pa., to accept a similar position with the Link-Belt Engineering Company. In 1896 and 1897 he was draftsman for the Corliss Engine Company, Providence, R.I., and the following year for the Marine Machine & Conveyor Co. in New York. From 1898 to 1901 he was associated with the Filer & Stowell Co., Milwaukee, Wis., as chief draftsman and engineer. He then spent four years as mechanical engineer for the Brown Corliss Engine Company, Corliss, Wis., and a year in the position of chief draftsman for the Power & Mining Machinery Co., Cudahy, Wis. For three years, beginning in 1906, he was connected with the Wisconsin Engine Company of Corliss. Since 1909 he had been mechanical engineer for the Allis-Chalmers Manufacturing Company of West Allis and Milwaukee, Wis.

Mr. Andersson became a member of the A.S.M.E. in 1913. He is survived by his widow, Linnea (Hoyer) Andersson, whom he married in 1905, and by one son, Malcolm A. Andersson.

GILBERT L. H. ARNOLD

Gilbert L. H. Arnold, a member of the A.S.M.E. since 1899, died at his home in Stamford, Conn., on February 1, 1931. Mr. Arnold was born in that city on October 12, 1865, and secured his early education there. He was graduated from the Sheffield Scientific School of Yale University in 1886 with a Ph.B. degree in mechanical Engineering. His early experience was secured as a draftsman for the Yale & Towne Co., Stamford, and with F. C. and A. E. Rowland, New Haven. In 1893 and 1894 he assisted in the design, construction, and installation of Belleville boilers on the S.S. *North West* for the Northern Steamship Company, and later had charge of repairs to the boilers on this vessel and on the *Northland* for the same company. For a time he was connected with the Atlas Portland Cement Company, Northampton, Pa., as chief engineer.

About 1904 Mr. Arnold became associated with Frederick A. Waldron, consulting engineer, New York, with whom he remained until his retirement from business in 1925. Concerning his work during these years Mr. Waldron wrote as follows:

"Mr. Arnold's modesty and retiring disposition have hidden from publicity his engineering accomplishments and foresight in the de-

sign of reinforced-concrete and structural steel. As far back as 1906 he developed and used the mathematical data for reinforced concrete now demanded by law. Among his outstanding achievements were the woodworking building (reinforced-concrete) for the National Cash Register Company (1906), service plant (reinforced-concrete and structural steel) of the Edison Electric & Illuminating Co. of Boston (1911–1912), and the John Hancock Mutual Life Insurance Building (reinforced-concrete and structural steel), Boston (1920–1921).

"His versatility and adaptability to engineering problems were well developed, and on data research and special machine design his ability was far above the average. These accomplishments, combined with diplomacy and excellent judgment, will be a loss to the engineering profession."

Surviving Mr. Arnold are his widow, Carrie Elizabeth (Adams) Arnold and three sons and two daughters, John A. Arnold, Englewood, N.J., Edmund S. Arnold, New York, N.Y., and Alfred, Nancy, and Elizabeth Arnold, Stamford, Conn.

JOHN CORLUS WHITE BAKER

John Corlus White Baker, who died at his home in Naugatuck, Conn., on July 15, 1931, was born on January 20, 1865, at Long Branch, N.J. His technical education was secured through the International Correspondence Schools, from which he was graduated in 1902 as a mechanical engineer. He also served an apprenticeship as a machinist with the Wharton Railroad Switch Company of Jenkintown, Pa., and was subsequently employed as foreman by that company.

He secured his early shop experience with the Naugatuck Manufacturing Company and the Excelsior Needle Company, with which he was connected in 1895 and 1896. Later experience was obtained in the Engineering and Repair Departments of Plant No. 4 of the Goodyear Metallic Rubber Shoe Company, a subsidiary of the U. S. Rubber Co. He served successively as foreman, assistant superintendent of construction, and master mechanic at this plant, which later became the Rubber Regenerating Company. From 1920 until 1931, when he retired from active business, he was plant engineer and consulting engineer for that company. Mr. Baker was responsible for the design of special machines for use in rubber mills.

A sister, Kate S. Baker, of Naugatuck, survives Mr. Baker. He had been a member of the A.S.M.E. since 1904.

THOMAS DENT BANKS

Thomas Dent Banks was born in Newcomerstown, Ohio, on December 24, 1885, and attended the high school there. He was graduated from Ohio State University in 1910 with an M.E. degree. His first technical experience was obtained during summer vacations with the Mesta Machine Company of Pittsburgh and the Hocking Valley Railway of Columbus. Following his graduation he secured a position as assistant superintendent of the Garbage Disposal Plant of the City of Columbus. The following year he was made assistant engineer of the Construction Division, and subsequently superintendent of the Division of Garbage and Refuse Disposal. He went to Marion, Ohio, in 1920 to become chief engineer for the Marion Tire & Rubber Co., having charge of the construction of buildings and machinery, factory maintenance, and power plant operation. About a year later he returned to Columbus as superintendent of the power plant at the Ohio State University.

He was stricken with paralysis on July 5, 1930, and had been subject to heart attacks since then. His death occurred on September 14, 1931. His father, Thomas A. Banks, died about seven weeks later. He is survived by his mother and by his widow, Ethel Banks, and three children.

In 1918 Mr. Banks enlisted for overseas reclamation work and was commissioned a first lieutenant. The unit was not sent, however, and after the armistice he was transferred to the Reserve Corps and subsequently was commissioned a captain in the Quartermaster Corps, Fifth Corps area, Fort Hayes, Columbus, Ohio. He was a member of the Faculty Club of the Ohio State University, and was affiliated with the Odd Fellows. He became a junior member of the A.S.M.E. in 1910 and was promoted to full membership in 1921. He was a member of the Columbus Symphony Orchestra.

WILLIAM F. BARNES

William F. Barnes, who died at Rockford, Ill., on December 28, 1930, was born at Mt. Morris, N.Y., on August 6, 1841. After completing his education, he became president in 1874 of the W. F. & J. Barnes Co. of Rockford, Ill., and served continuously in that capacity until his retirement in 1906. He had been a member of the A.S.M.E. since 1886.

REINOLD BERRENBERG

Reinold Berrenberg, owner and general manager of the American Rotary Pump Company, Roxbury, Mass. (now known as the R. Berrenberg Co.), died on March 25, 1931. Mr. Berrenberg was born near Cologne, Germany, on November 1, 1856, the son of Wilhelm and Maria Berrenberg. He served four years as an apprentice in a shop owned by his father and took charge of the shop for two years following that. For three years he was engaged in military service in Germany as first mechanic. He came to the United States in 1882 and was employed for three years by the Osborne Machine Company, builders of marine and stationary engines, as machinist and foreman. He then established his own business in this field, taking up also the manufacture of incandescent electric lamps in 1895. From 1900 to 1903 he was employed as a foreman in a shop manufacturing switchboard and woodworking machinery. During the next ten years he was connected with the Trimount Rotary Power Company of Boston in the design and construction of rotary compressors and pumps for all purposes. Since that date he had been general manager of the American Rotary Pump Company.

Mr. Berrenberg had been a member of the A.S.M.E. since 1913. He married Mary J. Berghaus, in Boston, in 1897. Five daughters and a son survive him.

ARTHUR OLIN BERRY

Arthur Olin Berry, since 1914 senior mechanical engineer for the Division of Valuation, Southern District, Interstate Commerce Commission, died at his home in Chattanooga, Tenn., on May 18, 1931. He is survived by his widow, Helen (Converse) Berry, whom he married in 1904, and by one daughter, Doris (Berry) Rountree, of Chattanooga.

Mr. Berry was born in Holyoke, Mass., on April 29, 1878, the son of Isaac and Maria Fanning (Stewart) Berry. He attended the public schools of that city and was graduated from Sibley College, Cornell University, in 1901, with an M.E. degree.

During the three years after his graduation Mr. Berry served a special apprenticeship and worked with the Boston & Albany Railroad at Springfield, Mass. His work included road tests of locomotives. In 1903 he was appointed division master mechanic at the Rensselaer, N.Y., shops. From 1905 to 1911 he was in the employ of the Lake Shore & Michigan Southern Ry., for two years at Collinwood, Ohio, as general foreman of the locomotive department, and during the remainder of the time at Elkhart, Ind., as superintendent of shops. At Collinwood he had charge of the blacksmith shop and brass foundry, as well as repairing and building locomotives, and at Elkhart he also supervised the foundry which supplied the entire road with its gray iron castings, and made changes which increased the capacity of the foundry about thirty-three per cent.

In 1911 Mr. Berry became assistant master mechanic of the Lake Erie & Western R.R. at Lima, Ohio. During his three years with this road he had charge of the car and locomotive departments, conducted road tests of different classes of bituminous coal, and redesigned caboose cars and the braking equipment of passenger cars to conform to the state laws of Indiana and the requirements of the Interstate Commerce Commission.

In 1914 he was appointed senior mechanical engineer for the Southern District of the Interstate Commerce Commission (Division of Valuation), at Chattanooga, Tenn. In 1921 he took up consulting engineering in that city and three years later was appointed director of smoke abatement, which position he retained until his death.

Mr. Berry became a member of the A.S.M.E. in 1914. He belonged to the Masonic fraternity.

CHARLES SPAFFORD BLAKE

Born at Windsor Locks, Conn., on October 25, 1860, Charles Spafford Blake was educated in the public schools of Springfield, Mass., and Jersey City, N.J., where for a time he engaged in newspaper work as a metropolitan district reporter for the United Press Association. His aptitude for things mechanical led him to abandon the journalistic field and to serve an apprenticeship at the Central Iron Works, Jersey City, a firm that built engines and boilers. Before he had reached his twenty-first birthday he was licensed as an engineer for small vessels and shortly afterward he was certified as chief engineer of ocean-going steamers. Shortly before the close of the Chile-Peruvian war he was commissioned as chief engineer in the Peruvian Navy and was awaiting orders when hostilities ended.

After considerable experience in marine engineering, Mr. Blake entered the boiler insurance field in 1884 as an inspector for the American Steam Boiler Insurance Company. Within three years he had become chief inspector at that company's Philadelphia office and subsequent to that was made adjustor for its Chicago agency. During the last four years which he spent in Chicago he was manager of a brass manufacturing works and consulting engineer in the boiler insurance field.

Mr. Blake became identified with The Hartford Steam Boiler Inspection and Insurance Company on June 1, 1898, as its general agent in Hartford, and six years later he was advanced to the position of supervising general agent. In 1907 he was elected second vice-president and, a year later, was made secretary. He served in that capacity until in 1916, when he was made a director and at the same time elected to the presidency. He was made chairman of the board of directors on February 8, 1927.

Evidence of the confidence his competitors had in him was his annual election for 13 years as president of the Steam Boiler and Flywheel Service and Information Bureau. At various times he was a member of the administrative council of the American Uniform Boiler Law Society, vice-president of the International Association of Casualty and Surety Underwriters, president of the Insurance Institute of Hartford, and director of The Boiler Inspection and Insurance Company of Canada. At the time of his death he was a director of the Phoenix State Bank and Trust Company.

He was prominently identified with church and civic enterprises, and as a member of Asylum Hill Congregational Church served as deacon for several terms, besides being a member of the Ecclesiastical Society's Committee. At one time he was president of the City Missionary Society and was thus actively engaged in the work of the society at its Village Street Mission. He served for a term as president of the City Club and was a member of the Hartford Club and the Hartford Golf Club. He became a member of the A.S.M.E. in 1912.

Mr. Blake was the son of John W. and Lucy Chapin (Hitchcock) Blake. He married Miss Elizabeth Reeves of Newark, N.J., in 1882, and is survived by her and by two sons, Charles Edgar of Windsor and Stanley Reeves of Hartford. He died on March 31, 1931.

ROBERT HARBISON BOOTH

Robert Harbison Booth, who retired in December, 1930, on account of ill health, died at his home in Providence, R.I., on March 22, 1931. He is survived by his widow, Edith Gardner (Andrews) Booth, whom he married in 1907, and by one son.

Mr. Booth was born at Chester, Pa., on November 11, 1883, the son of John W. and Ella F. (Ellis) Booth. He studied mechanical engineering for three years at the Massachusetts Institute of Technology, leaving in 1905 to study steel rolling mill management and practice at the Moline, Ill., plant of the Republic Iron & Steel Co. After three years there he went to Bettendorf, Iowa, as assistant general inspector for the Bettendorf Steel Car Company.

In 1910 Mr. Booth became a member of the staff of Fred A. Kerry, consulting industrial engineer and accountant, Chicago, Ill. This organization was dissolved in 1915 and Mr. Booth continued independently in the same line of work during the next three years. His experience during these eight years covered wholesale and retail stores, foundries, forge shops, bridge and structural shops, metal working plants, etc. In 1918 he accepted a position as superintendent, later becoming assistant to the president, of the Bridgeport Brass Company, Bridgeport, Conn. His duties related particularly to wage rates and incentives and personnel problems. He resigned his position in 1925 to become vice-president and general manager of Whitney-MacDonald, Inc., Philadelphia, and in 1927 was made president of that company, which was reorganized as the MacDonald Corporation. During 1930 he was general manager for the U.S. Bobbin & Shuttle Co., Manchester, N.H.

Mr. Booth became a member of the A.S.M.E. in 1922.

HARRISON SEBA BOWEN

Harrison Seba Bowen, for more than thirty years associated with the Robert W. Hunt Company, Chicago, died of coronary thrombosis on February 14, 1931, following a brief illness.

Mr. Bowen was born at Des Moines, Iowa, on July 13, 1872, the son of Cromwell and Martha (Fletcher) Bowen. He attended high school in Des Moines and then entered Iowa State College, Ames, from which he received the degree of B.M.E. in 1894. A year later he took his M.E. at Cornell University. Prior to his connection with the Hunt company he was employed for about six months by the Missouri, Kansas, and Texas Railroad, Parsons, Kan., and for the same length of time by Booth, Garret & Blair, in inspecting and testing work in Pittsburgh and Philadelphia.

As mechanical engineer for the Hunt company Mr. Bowen was engaged in the investigation and efficiency testing of all kinds of power units. This work covered such important installations as the Chicago water works pumping stations and drainage pumping station units. The mechanical efficiency testing work on heating and power plants under the direction of Mr. Bowen was a pioneer work in the Chicago area. Many installations were reviewed and tested and brought to the highest state of mechanical and fuel consumption uses. Mr. Bowen was engaged in research with complicated and difficult mechanical installations both from the practical operating standpoint and from the standpoint of changes and advance in the art of power use.

Mr. Bowen became a junior member of the A.S.M.E. in 1895 and was promoted to full membership in 1908. He also belonged to the Western Society of Engineers.

Surviving Mr. Bowen are his widow, Katherine (Christman) Bowen, whom he married in 1898, and two sons, Cromwell and Llewellyn Bowen.

JOSEPH BOYER

Joseph Boyer, chairman of the board of directors of the Burroughs Adding Machine Company, died of pneumonia on October 24, 1930, at his home in Detroit, Mich.

Mr. Boyer was a Canadian by birth. His parents, David and Modlany (Brown) Boyer, lived on a farm near Pickering, Ontario, about thirty miles from Toronto, and he was born there on September 19, 1848. At the age of eighteen he persuaded his father to take him to Oshawa where some friends of his were working in a machine shop known as the Hall Works. Three years later, with the opening of the transcontinental railway, he was invited to join some friends who had decided to go to California. His father had died and his mother mortgaged the farm to secure the necessary fare for the trip. Eventually he arrived at San Francisco, where he found work at the Risdon Iron Works for about six weeks. There being nothing further available, he took an opportunity to secure a return ticket to St. Louis, Mo., where he worked for a year or more at the Fulton Iron Works. He then worked at Leavenworth for about a year, after which he returned to St. Louis and secured employment at the St. Louis Type Foundry. Next he was engaged by the Victor Sewing Machine Company to adjust machines.

About 1876 Mr. Boyer left the Victor company to help with the manufacture of a new sewing machine. The company failed and Mr. Boyer and another employee took over the tools and started a small machine shop under the firm name of Boyer & Swaine. Not long afterward he bought out Mr. Swaine's interest and established larger quarters elsewhere in the city, where he remained until 1900. During these years Mr. Burroughs came to his shop for an assistant to work with him on the development of his adding machine. Mr. Boyer's shop built the first few hundred of these machines for the American Arithmometer Company, which later took over their manufacture, though still sharing the same quarters. Mr. Boyer was elected vice-president and a director of this company in 1898. During this period Mr. Boyer invented the pneumatic hammer, the air drill, and the railway speed recorder, and eventually it became necessary to enlarge the shop to provide space necessary for the manufacture of both the adding machine and the pneumatic hammer. Toward 1900 still more space was required, and Mr. Boyer decided to move his business, the Boyer Machine Company, to Detroit.

After a year in his new location Mr. Boyer sold out to the Chicago Pneumatic Tool Company. The following year he was made president of the American Arithmometer Company, which relocated in Detroit in 1904 and was reorganized as the Burroughs Adding Machine Company the following year. Mr. Boyer resigned from the presidency and was made chairman of the board in 1920, at the age of 72, but never lost his active interest in the work, and spent much of his time in the experimental and engineering departments.

Mr. Boyer became a member of the A.S.M.E. in 1913 and also belonged to a number of clubs in Detroit. Surviving him are a son and four married daughters. His wife died in 1913.

HARRY BROADBENT

Harry Broadbent, for more than thirty years associated with the Philadelphia Electric Company, died on March 17, 1931. Mr. Broadbent was born at Oldham, Lancastershire, England, on September 13, 1866. The following year his parents came to Providence, R.I., where he attended the public schools and served an apprenticeship as journeyman machinist with the Harris-Corliss Engine Works.

The family moved to Philadelphia in 1887, and he secured a position

as machinist with Robert Wetherill & Co., Chester, Pa., where he remained only a few months. During the next six years, he was similarly employed in the Maintenance Department for cable roads and motive power of the Philadelphia Traction Company; by Chambers Bros. & Co., manufacturers of brick and paper-folding machinery in Philadelphia; and by the John Lang Paper Company of that city. In 1894 he became engineer at the power house of the Jenkintown Light Company, Jenkintown, Pa. He entered the employ of the Philadelphia Electric Company in a similar capacity in 1899 and was made inspector of the Mechanical Design and Construction Department in 1917. As chief engineer, Mr. Broadbent took charge of reconstruction and extension work at several stations of the company in Philadelphia. He supervised the installation of new equipment and the maintenance of machinery in operation. He was directly connected with the design and construction of the Chester and Delaware Stations, which were built after he was appointed to the position of inspector.

Mr. Broadbent became a member of the A.S.M.E. in 1922. He was very fond of music and sang in the Episcopal choir in West Philadelphia for many years. He is survived by a sister, Mary Alice Broadbent, of Philadelphia, with whom he had made his home since the death of his parents in 1911.

WILLIAM LEROY BRYANT

William LeRoy Bryant, president and general manager of the Bryant Chucking Grinder Company, Springfield, Vt., died there on April 25, 1931, of heart disease. His widow, Blanche (Brown) Bryant, whom he married in 1900, and two sons survive him.

Mr. Bryant was born at Northfield, Vt., on April 29, 1875, the son of William Nelson and Sally Angelia (Holbrook) Bryant. He attended the Black River Academy at Ludlow, Vt., and entered the University of Vermont with the class of 1898. He was obliged to leave college at the end of his junior year but was presented his degree in 1921 by the college "as of the class of 1898."

All of Mr. Bryant's business experience was obtained in Springfield. In 1897–1898 he was employed by the Jones & Lamson Machine Co. in general shop work, and subsequently he was draftsman and chief engineer until 1909 when he organized the Bryant Chucking Grinder Company.

Mr. Bryant had a number of inventions to his credit, holding patents for single slide control for internal and cylindrical grinders, hole and face grinders, multiple spindle automatic internal grinders, grinding wheel spindles, and fluid gages for precision measurements. He became a member of the A.S.M.E. in 1910 and also belonged to the Society of Automotive Engineers and the Vermont Society of Engineers. He was a director of the Associated Industries of Vermont and of the First National Bank of Springfield, a member of the Masonic fraternity and of the Machinery Club in New York. Mr. Bryant belonged to the glee club and band while in college, and played in local bands later.

GEORGE BUCHANAN

George Buchanan, president of the Long Island Foundry Company, Long Island City, N.Y., was a native of Pollokshaws, Scotland, where he was born on February 6, 1867. He came to the United States about the year 1890, and until 1918 was superintendent of the McGee Foundry Company, Long Island City. He was then made vice-president of the Long Island Foundry Company, later succeeding to the office of president. He had been an associate of the A.S.M.E. since 1921. His death occurred on May 22, 1931.

J. NORMAN BULKLEY

J. Norman Bulkley, consulting engineer, Johannesburg, South Africa, died on October 6, 1931. Mr. Bulkley was born at Memphis, Tenn., on September 17, 1867. He received an S.B. degree from the Massachusetts Institute of Technology in 1889, and during the remainder of that year was draftsman for the Wright Engineering Company of Boston. The next year he was employed as chief engineer by the Pennsylvania General Electric Company at Scranton; from 1894 to 1897 he was assistant engineer and in charge of mining machinery, designing machinery and supervising the erection of electric mining plants.

Mr. Bulkley went to Johannesburg in 1902 as chief engineer for the United Engineering Company, Ltd., a position which he held for seven years. He had engaged in general consulting practice in the mechanical and electrical fields since 1909. For five years he was consulting electrical engineer for the General Mining & Finance Corp. of Johannesburg. He spent several years in London and New York in consulting work and returned to South Africa in 1922. Among his clients were the African and European Investment Company, Guest Sykes & Chapman Ltd., Manganese Corporation, and other Johannesburg firms. Mr. Bulkley became a member of the A.S.M.E. in 1902.

STANLEY HALE BULLARD

Stanley Hale Bullard, vice-president and works manager of The Bullard Company, formerly The Bullard Machine Tool Company, of Bridgeport, Conn., died on March 22, 1931, at his home in Fairfield, Conn., of heart disease. A heart attack about a year earlier had forced him to give up his activities for some time but he had begun to renew them when he suffered another attack.

Mr. Bullard was the son of Edward Payson Bullard, the founder of The Bullard Company, and Alice Martha (Camp) Bullard, and was born on July 4, 1877, in Hoboken, N.J. After his graduation in 1895 from the New York Military Academy he became an apprentice machinist at the Bullard works and subsequently entered upon the sales work of the company. In 1901 he managed the Bullard exhibit at the Pan-American Exposition in Buffalo, N.Y. He served successively as manager of the New York office, manager of the Eastern Sales District, and general sales manager. He took up the duties of general works manager in 1915 and was made vice-president of the company three years later.

In 1917 Mr. Bullard served as vice-president and member of the management council of The Bullard Engineering Works, organized to manufacture 155 mm. G.P.F.'s. He developed the equipment and operating plans for this company and cooperated in the development of the Bullard boring mills, vertical turret lathes, and the Bullard Mult-Au-Matic. He contributed articles on machine tool manufacture and use to the technical press.

E. Kent Hubbard, president of the Connecticut Manufacturers' Association, issued the following statement on the death of Mr. Bullard:

"The industrial life of the state and the nation suffers in the death of Stanley H. Bullard. Identified as he was with a company which has made notable contributions to the advancement of modern machinery design and construction, his name is probably most closely associated with that trade. But his active interest in cooperative enterprises which characterize the business picture of today made him a recognized and respected figure wherever business men gathered. As a citizen, as a manufacturer, and as a cooperative spirit, his loss will be keenly felt."

The "cooperative enterprises" to which Mr. Hubbard refers were numerous and varied. Mr. Bullard was director of the United States Chamber of Commerce for two terms; first president of the National Association of State Chamber of Commerce Officials; president for four years of the Connecticut Chamber of Commerce; and vice-president of the Bridgeport Chamber of Commerce. He was an original member of the Connecticut Manufacturers' Association and at the time of his death was a member of its executive board and its special advisory committee. He was also an original member of the New England Council, formed about five years before his death, and had served on its executive committee and external relations committee. He had been a member of the Connecticut Division of the New England Governors Railway Advisory Commission, known as the Storrow Committee, which was appointed to make a survey of railway transportation in New England. He was also a member of the New England Shippers Advisory Board of the American Railway Association. Among the engineering societies to which he belonged were the A.S.M.E., which he joined in 1920, the Society of Automotive Engineers, the National Machine Tool Builders Association, and the Atlantic Deeper Waterways Association, of which he had been vice-president. He was vice-president of the Bridgeport Manufacturers' Association and a member of the Bridgeport Engineering Institute. He also participated in the civic affairs of Fairfield, being secretary of the Board of Education there and serving on the building committee of the board, and also being director of the Fairfield Bank & Trust Co. and the Home Building and Loan Association of Fairfield. His clubs included the Engineers' in New York, the Brooklawn and Algonquin in Bridgeport, and the Black Rock Yacht Club, Fairfield Beach Club, and Fairfield County Hunt Club, and he was a member of the Masonic fraternity.

Surviving Mr. Bullard are his widow, formerly Grace Cleaveland, of Bridgeport, whom he married in 1901, a son, Stanley Hale, Jr., and two daughters, Mrs. John Budd, of St. Paul, Minn., and Miss Katherine Bullard of Fairfield.

LOUIS STELLE BURBANK

Louis Stelle Burbank, who was injured in an automobile accident on October 12, 1930, died at the Milford (Mass.) hospital on January

6, 1931. He is survived by his widow, Grace (Wilson) Burbank, whom he married in 1905. She was also injured but was able to leave the hospital shortly before her husband's death. Also surviving him are two sons and a daughter, Davis E. Burbank, Worcester, Mass., Thurlow G. Burbank, New York, N.Y., and Mrs. Kester S. Lindsay, St. Louis, Mo.

Mr. Burbank was born at Lexington, Ky., on May 22, 1866, the son of Davis and Martha (Cox) Burbank. In addition to a year of study at Macalaster College, St. Paul, Minn., he had private instruction in technical subjects, and served a two-year apprenticeship as a machinist with C. M. Breuer, Fergus Falls, Minn. His early shop experience was secured with the St. Paul, Minneapolis & Milwaukee Ry. and Union Iron Works in Fergus Falls, Barnesville, and Minneapolis, Minn. He did some early work on the design of sugar and mining machinery and during 1899 was located in Boston, engaged on patent drawings and designing. A machine which he designed at this time for putting a string through the uppers of shoes and tying a knot in it was patented in 1893.

His first connection of importance was with the Cereal Machine Company, Worcester. For a number of years he designed all of the special machinery for this company, being located first in Boston and later in Worcester, where he was superintendent of machinery. Subsequent to this connection he was mechanical engineer for the Natural Food Company, Niagara Falls, N.Y. These two companies were forerunners of the present Shredded Wheat Company, "shredded wheat" being the name given to the product by Mr. Burbank.

From 1902 to 1908 Mr. Burbank engaged in mechanical engineering private practice in Niagara Falls, Worcester, Mass., and Phoenix, Md. In 1908 he served as president of the Corn Crystal Company, Worcester, and for the next nine years was mechanical engineer and assistant chief draftsman for the Draper Company, Hopedale, Mass. He resigned this position in 1916 to become mechanical engineer for the Ludlow Manufacturing Associates, Ludlow, Mass. In 1919 he was engaged as chief engineer of the Manville Manufacturing Company, Waterbury, Conn., and since that year had been with the Reed & Prince Mfg. Co., Worcester, as chief engineer since 1921.

Mr. Burbank became a member of the A.S.M.E. in 1898. He also belonged to the Engineering Society of Western Massachusetts and the Masonic fraternity.

WALTER SAFFORD BURKE

Walter Safford Burke, for some years inspector of the grounds and buildings of Harvard University, died on August 5, 1931. He is survived by his widow, Frances B. Burke, whom he married in 1893, and by a married daughter, Mrs. Ralph H. Wales.

Mr. Burke was born at Babcock Hill, Oneida County, N.Y., on December 30, 1866, the son of Albert G. and Clarissa (Booth) Burke. He was educated at the United States Naval Academy, from which he was graduated in 1887. He served in the Navy for ten years and then went to Harvard as instructor in the Mechanical Engineering Department. He was made an assistant professor of mechanical engineering in 1894. During the World War, he was stationed at the United States Navy Yard as Lieutenant-Commander, United States Navy.

In addition to his duties at Harvard, Mr. Burke was connected with the consulting firm of Burke & Hughes from 1906 to 1912.

Mr. Burke became a member of the A.S.M.E. in 1913.

NOBLE CHASE BUTLER, JR.

Noble Chase Butler, Jr., whose death occurred on June 7, 1931, was born at New Albany, Ind., on July 27, 1874, the son of Noble Chase Butler and Annie (Browning) Butler. After completing his work at the Indianapolis High School, he attended Purdue University and then entered Rose Polytechnic Institute, from which he was graduated with a B.S. degree in 1899. From then until 1916, he worked in the Testing Department of the Henry R. Worthington Hydraulic Works in Brooklyn, N.Y. He made graphical analyses of water-works engines to determine their most suitable parts, and also studied the arrangement of engines and accessories for plants. He made plans for the layout of water works and condenser installations and superintended the erection and testing of such equipment.

In 1916, Mr. Butler resigned from the Worthington company to handle New York sales for the Wilson-Snyder Company, manufacturers of all kinds of pumping equipment. In 1918, he superintended the erection of an oil line pumping station at the wells and a sea loading station at the coast in the Southern Oil Field of Mexico, for the Cortez Oil Company, as representative of the Wilson-Snyder Company. After completing this work, Mr. Butler was engaged as engineer in the Technical Department of the Vacuum Oil Company, New York. He analyzed lubrication requirements in central power stations and mills in various industries and made a study of machinery to determine the proper selection and application of lubricants. His work for the Standard Oil Company of New York, for which he became sales engineer in 1922, resulted in his appointment as chairman of its Committee of Industrial Lubricating Engineers, in which capacity he acted as chief engineer and consultant on all major lubricating problems both as to lubricants to be used and methods of application in all types of industries.

Mr. Butler first became a member of the A.S.M.E. in 1900. He resigned two years later but joined the Society again in 1927. He is survived by his widow, Ruth G. (Sears) Butler, whom he married in 1925.

WILLIAM ALFRED BUTLER

William Alfred Butler, who died on April 17, 1930, was born on January 19, 1868, at Cincinnati, Ohio. After completing his public school education, he went to work in 1886 as assistant to the general repairman of the C. H. Kilgour Narrow Gage Railway in Cincinnati. After four years in this work, he secured a position as chief engineer of the plant of Benjamin Hey & Co. in that city. From 1893 to 1895 he was night chief engineer of the Cincinnati Edison Electric Company, and for the next six years engineer for the Cincinnati Street Railway Company. In 1901, when the latter company was merged into the Cincinnati Traction Company, he was appointed superintendent of steam machinery repairs and later became superintendent of construction and maintenance of the five stations belonging to the company. In 1906 he was made chief engineer of the Pendleton Power Station of the company, where he remained for seven years. He was next connected in 1913 with the Duquesne Light Company of Pittsburgh as assistant superintendent of power stations. At the time of his death he was chief engineer of the Braun Brothers Baking Company of Pittsburgh.

He had been a member of the A.S.M.E. since 1915.

LEONARD CAHOON

Leonard Cahoon died of cancer at his home on April 1, 1931, after an illness of six months. Surviving him are his widow, Matilda (Watts) Cahoon, whom he married in 1909, and two daughters, Virginia and Janice. Mrs. Cahoon was a member of the Utah State Legislature in the session preceding her husband's death.

Mr. Cahoon was the son of Mary Erekson Cahoon, who also survives him, and Andrew Alonzo Cahoon, who died in 1924. He was born in Salt Lake City on December 10, 1881, and received his early education there. He studied mining and mechanical engineering at the University of Utah, which conferred a B.S. degree upon him in 1905. He was secretary of the board of directors of the University Club in Salt Lake City at the time of his death.

Following his graduation Mr. Cahoon gave five years to design and construction work for the U.S. Smelting, Refining & Mining Co. of Salt Lake City and Boston. Among the plants built under his supervision were rock crushing and loading plants in Utah, a smelter and bag houses at Kennett, Calif., smelter for the Needles Mining & Smelting Co. at Needles, Calif., as well as mining equipment for the company at its Kingman, Ariz., mines, and electrostatic concentrator baghouse and arsenic plants at Midvale, Utah.

In 1910 and 1911 Mr. Cahoon was engaged in the design and construction of a complete new hoisting plant for the Chief Consolidated Mining Company at Eureka, Utah, following which he superintended the construction of reinforced concrete and steel buildings for the James Stewart Company, including a theater building in Salt Lake City. During 1912 and 1913 he was placed on special design of haulage equipment and ore storage equipment for the International Smelting Company, Tooele City, Utah. Next, as a representative of the P. J. Moran Contracting Company, Salt Lake City, he superintended the construction of the Administration Building for the University of Utah. When this job was completed he took a position as engineer and superintendent of shops with the Galigher Machinery Company, Salt Lake City, with which he remained for about six years. He then went into business as sales manager and vice-president of the Stratton-Cahoon Company in Salt Lake City, western representative for the Weller Manufacturing Company, Republic Flow Meters Company, Erie City Iron Works, and Powers Specialty Company, handling equipment used in mines, factories, smelters, etc. He was later appointed western representative for the Foster Wheeler Corporation of New York, with headquarters at Salt Lake City, the position which he held at the time of his death.

Mr. Cahoon became a member of the A.S.M.E. in 1921. He was past-president of the Utah Society of Engineers and prominent in

politics, being a member of the Republican County Committee at the time of his death.

JAMES HENRY CALDWELL

James Henry Caldwell, chairman of the Board of Directors of the Ludlow Valve Manufacturing Corporation, Troy, N.Y., was born at Mobile, Ala., on March 21, 1865. His parents were Edward Holland and Carolina A. (Shields) Caldwell. He prepared for college at schools in Mobile, Ala., Salisbury, Md., and New York, N.Y. He was graduated from Rensselaer Polytechnic Institute, Troy, N.Y., in 1886 with a B.A. degree.

For eighteen years following his graduation, Mr. Caldwell was associated with the Mobile Gas & Electric Co. He engaged in consulting work and served as vice-president of the company. From then until his death on November 18, 1931, he was identified with the Ludlow company. He was made vice-president and general manager in 1894 and president in 1908.

Mr. Caldwell became a member of the A.S.M.E. in 1912. He also belonged to the Society of Professional Engineers of the State of New York, the American Foundrymen's Association, American Gas Institute, American Water Works Association, and the National Gas and Petroleum Association of Canada. He was an associate member of the American Museum of Natural History. Mr. Caldwell was elected president of the Troy Trust Company when it was organized in 1902. He resigned that position in 1913 and was serving as chairman of the board at the time of his death. He was treasurer of the Rensselaer Improvement Company, trustee and vice-president of the Troy Savings Bank, vice-president of the National State Bank of Troy, and of a number of railroads, including the Rensselaer & Saratoga, Albany & Vermont, and the Troy & Schenectady. He was vice-president and trustee of Rensselaer Polytechnic Institute and a dormitory of the Rensselaer campus was named for him. He had been active in the community affairs in Troy, serving as president of its Samaritan Hospital, of the Public Library, and of the Troy Chamber of Commerce. He married Margery Christie of Troy, in 1887, and is survived by two daughters.

ARTHUR LATHAM CHURCH

Arthur Latham Church, secretary and assistant treasurer of the Baldwin Locomotive Works, Philadelphia, Pa., died on June 25, 1931. Mr. Church was born in Philadelphia, on October 11, 1858, the son of William A. and Elizabeth (Barker) Church. His wife, Louise (Brant) Church, whom he married in 1888, died in 1929. He is survived by one son and by three grandchildren.

Mr. Church was graduated from the Towne Scientific School of the University of Pennsylvania in 1878, with a B.S. degree in mechanical engineering. The next four years were spent in the shops and drafting room of the William Cramp & Sons Ship & Engine Building Co. of Philadelphia. From 1882 to 1884, he served as electrician and oiler on the S.S. *Queen of the Pacific* and as assistant engineer on the S.S. *City of Peking* and S.S. *Granada*. He also did some work as designer for the Union Iron Works of San Francisco. During the next two years, Mr. Church was chief engineer of the Electrical and Novelties Exhibitions of The Franklin Institute and superintendent of The Spring Garden Institute. In 1886, he began his long connection with the Baldwin Locomotive Works as manager of the Department of Repairs. He was appointed assistant to the president in 1915, and had been secretary and assistant treasurer since 1920. He was always interested in shipbuilding, and from 1912 until it was dissolved in 1920, was manager of the Essington Shipbuilding Company, Ltd.

Mr. Church joined the A.S.M.E. in 1917. He was also a member of The Franklin Institute, the Pennsylvania Academy of Fine Arts, the Historical Society of Pennsylvania, and a number of clubs. He was a trustee of the University of Pennsylvania and a manager of the Preston Retreat, The Spring Garden Institute, and the University Hospital of Philadelphia. He was the author of "The Training of a Secretary."

BERTRAND JOSEPH CLERGUE

Bertrand Joseph Clergue, president of The Waterbury Tool Company, Waterbury, Conn., died on March 28, 1930. He was born in 1873 at Bangor, Me., where he received his early training in the repair shop of the Bangor Street Railway Company. He spent three years at the Massachusetts Institute of Technology, and in 1895 accepted a position with the Penobscot P. & P. Co., at Veazie, Me. The following year he became assistant manager of the Lake Superior Power Company, where he remained for three years. From 1899 to 1902 he was manager of the Algoma Central Railway, Michigan Lake Superior Power Company, and Tagona Water & Light Co. Subsequently he did consulting work at Sault Ste. Marie, Ontario, Canada, and at Montreal, and for a time was vice-president and general manager of Universal Transmission, Ltd. of Montreal.

He became an associate member of the A.S.M.E. in 1907.

CLARENCE E. CLEVELAND

Clarence E. Cleveland, president of the Intervale Mills, Inc., Webster, Mass., died at the home of his sister in Worcester, on May 8, 1931. Mr. Cleveland was born in that city on August 31, 1865, the son of Edwin Clarence and Anna (Goddard) Cleveland. He was graduated from the Worcester Polytechnic Institute with a B.S. degree in 1886. By 1892 he had become a designer at the Intervale Mills at Quinebaug, Conn., and subsequently was made a partner in this company. An additional larger mill was built in 1904 under Mr. Cleveland's supervision and a great deal of new machinery installed during the next few years. Mr. Cleveland had charge of practically all of the engineering work for the two plants of the company. He was appointed treasurer in 1918 and in 1924 went to Webster, Mass., when the firm was relocated in that city. He was appointed president the following year.

Mr. Cleveland became a member of the A.S.M.E. in 1916. He is survived by his widow, Gertrude (Stevens) Cleveland, whom he married in 1894, and by two sons and a daughter, as well as by his sister, Mrs. J. Isabel C. Wood.

BENJAMIN DENVER COPPAGE

Benjamin Denver Coppage, who died on October 6, 1931, was born at Sudlersville, Queen Anne County, Md., on April 13, 1872. He was the son of Edward Keene and Georgia E. (Crouch) Coppage. He supplemented his public school education with correspondence courses and night classes at the Y.M.C.A. His first position was with the Baldwin Locomotive Works as a helper in the erecting shop. In 1890 and 1891, he was draftsman for the Edge Moor Iron Company and the Newport News Ship Building & Dry Dock Co. He returned to the employ of the Edge Moor Iron Company in 1892 and remained with that company until 1907, serving as chief draftsman and superintendent. He designed improved forms for a number of types of boilers and, while in charge of the shops, designed and put into operation many improvements in equipment.

For ten years, beginning in 1907, Mr. Coppage was connected with the Pusey & Jones Co. During his first year with the company, he reorganized the engineering department. For the next six years, he was works manager in charge of the engineering and production departments. He was made chief engineer in 1914, and his duties in that capacity included supervision of all patent matters and consulting work for the Patents Owning Company, Inc. While Mr. Coppage was associated with the company it built paper-making machines for producing sheets from 170 in. to 204 in. Mr. Coppage was intimately connected with the design and construction of these machines. He also prepared plans for building machine shops and improving the equipment of the plant.

From 1917 to 1925, Mr. Coppage was connected successively with the E. I. du Pont de Nemours & Co., Wilmington, as experimental engineer, with the District of Columbia Paper Manufacturing Company, Washington, D.C., as chief engineer, and with the Levgar Structural Company, N.Y., as production engineer. Since 1925, he had been draftsman for the Viscose Company, Marcus Hook, Pa.

Mr. Coppage became a member of the A.S.M.E. in 1915. He also belonged to The Franklin Institute, which presented him with a "Certificate of Merit" in 1925 for his invention of a testing instrument known as the plastometer.

Surviving Mr. Coppage are his widow, Elsie B. (Johnson) Coppage, whom he married in 1898, and one daughter, Mabel Coppage.

WILLIAM VALDEMAR DAM

William Valdemar Dam, managing director of Thompsons Engineering & Pipe Co., Ltd., Castlemaine, Victoria, Australia, died at Castlemaine on February 12, 1931. He was born at Otahuhu, near Auckland, New Zealand, on November 18, 1864, the son of Edward Thomas Köller and Elizabeth (Corliss) Dam. After preparatory work in private and state schools, he attended the Workingmens College at Melbourne. In November, 1881, he began a six-year apprenticeship with the Bay of Islands Coal Company at Auckland, working particularly on the manufacture and repair of mining equipment.

His first position after completing his apprenticeship was with the Austral Otis Engineering Company, Ltd., of Melbourne, as an

engine fitter and erector. During the thirteen years of his connection with this company he held the positions of outside foreman, machine-shop foreman, draftsman, quantity surveyor, estimator, and assistant manager. These titles indicate the general character of his work, which dealt with all classes of hydraulic elevators and auxiliary machinery, as well as other hydraulic and mining equipment. For about a year and a half he was engaged in treating different ores mechanically and chemically and experimenting with new mining machinery, and for two years he inspected elevators in Melbourne, Sydney, Adelaide, and Brisbane.

In July, 1900, Mr. Dam was appointed works manager for Thompson & Co., Castlemaine, where he was promoted successively to designing engineer, assistant general manager, general manager, and managing director. He devoted special attention to the subject of mining and dredging machinery and was responsible for the design and construction of highly successful large steam winding engines and numerous important sluicing plants.

Mr. Dam visited America and Europe in 1919, and while in England completed arrangements for the manufacture by his firm in Australia of large steam turbines and their condensing plant under license to the Metroplitan Vickers Electrical Company, of Manchester, England.

Mr. Dam possessed a great inherent mechanical aptitude and an extraordinarily retentive memory and was regarded as one of the foremost mechanical engineers of Australia. He was elected a member of the A.S.M.E. in 1906, and for many years belonged to the Victorian Institute of Engineers.

Mr. Dam married Mary Findlay in 1914, and is survived by her and by one daughter by a former marriage.

CHARLES DAY

Charles Day, chairman of the board of Day & Zimmermann, Inc., Philadelphia, Pa., died at the University Hospital in that city on May 10, 1931, following an illness of ten days. An eye disorder, which had developed a few days after his return from a trip to North Africa and which was at first attributed to the effects of the tropical sun, proved to be an organic affliction.

Mr. Day was born in Philadelphia on May 15, 1879, the son of Richard H. and Frances (Corson) Day. He attended the Germantown Academy and was graduated from the University of Pennsylvania with a B.S. degree in 1899. An M.E. degree was conferred upon him in 1903. He was superintendent of installation of power plant equipment and transmission machinery for the National Export Exposition at Philadelphia during the latter part of 1899 and then spent about two years as assistant superintendent and engineer of works for the Link Belt Engineering Company at Nicetown, Philadelphia.

In 1903 the engineering firm of Dodge & Day, specializing in management and construction work, was established. It became Day & Zimmermann, Inc., in 1911, with Mr. Day as president from 1916 until 1926, and chairman of the board since that time. Through his work with this firm Mr. Day became widely known as an authority on the construction and efficient equipment of industrial plants and the management of public service corporations. He lectured on these subjects before the Graduate School of Business Administration at Harvard, and at Columbia and Lehigh universities. He served as president, vice-president, or director of a very large number of public service companies, including railway, light, heat, and power. He was the author of many articles on industrial management, and in 1911 published a book on "Industrial Plants."

Mr. Day was called upon by the Government to serve in a number of important posts. He was made a trustee of the Emergency Fleet Corporation at the beginning of the World War and was appointed a member of a civilian board to investigate the efficiency of the navy yards. During the War he was a member of the storage committee of the General Munitions Board and conferred in France with General Pershing on means of expediting the transportation of troops and supplies to Europe. He was appointed to the Depot Board by the Secretary of War and was present at the War Council of the Allies in the winter of 1917. He was also engineering adviser to Colonel Edward M. House's commission.

Mr. Day became a junior member of the A.S.M.E. in 1902 and a member six years later. He was a member of the Bureau of Engineering Standards in 1913 and 1914 and of the Standardization Committee of the Society during the next two years. He also served from 1913 to 1917 as a member of the Subcommittee (of the Committee on Meetings) on Industrial Buildings.

Among the other societies to which he belonged were the American Institute of Electrical Engineers, the American Philosophical Society, the Taylor Society, and the Society for the Promotion of Engineering Education. He was a member of the board of managers of The Franklin Institute, a trustee of the University of Pennsylvania, and a director of the Pennsylvania Railroad and Fidelity-Philadelphia Trust Company. His clubs included the Racquet, the Engineers' Club of Philadelphia, the Engineers' Club of New York, the Philadelphia Cricket Club, Sunnybrook Golf, University and Rittenhouse Clubs.

Surviving Mr. Day are his widow, Margaret (Dunning) Day, whom he married in 1904, two sons, William L. and Charles C., and a daughter, Margaret D. Day.

VAN NESS DeLAMATER

Van Ness DeLamater, since 1915 associated with the Hyatt Roller Bearing Company, died on August 29, 1931. It is believed that he and his son, Van Ness, Jr., were drowned when their canoe overturned during a sudden storm on Green Lake, Algonquin Provincial Park, Ontario.

Mr. DeLamater was born at Hudson, N.Y., on July 3, 1878, a son of Ezra Doane and Anna (Van Ness) DeLamater. He attended high school in Hudson and Ithaca, N.Y., and was graduated from Cornell University in 1900 with an M.E. degree. He continued his studies in engineering and law at Cornell for a year and then served an apprenticeship at the Mt. Clare shops of the Baltimore & Ohio R.R., Baltimore, Md. During the next two years he was connected with the department of tests of that railroad, inspecting material and new equipment and conducting laboratory investigations. He was next employed for about six months by the American Steel Foundries Company, testing and reorganizing power plants in foundries. In 1905 and 1906, he was salesman in the New York district for the Star Brass Manufacturing Company. During the next two years he was employed by the Central Railroad of New Jersey, first as inspector of the motive power department, testing locomotives and power plants and designing new car shops, and later as acting assistant chief draftsman in the mechanical department in Jersey City. From 1908 to 1912 he was chief draftsman and mechanical engineer for the Rushmore Dynamo Works, Plainfield, N.J. He designed brass goods and tools, installed and operated producer gas and engine plants, supervised the construction and installation of equipment of concrete factory buildings, and developed direct-current and storage-battery lighting systems for automobiles.

Mr. DeLamater went to Winnipeg in 1912 as sales manager for the Canadian Fairbanks Morse Company, resigning that position in 1915 to become assistant sales manager in the motor bearings division at Detroit of the Hyatt Roller Bearing Company. He was transferred to Harrison, N.J., as assistant to the vice-president of that company in 1920 and since 1924 had been located at the Newark office, specializing in railroad bearing applications.

Mr. DeLamater became a member of the A.S.M.E. in 1913. He is survived by his widow, Jacqueline (Newton) DeLamater, formerly of California, whom he married in 1904, and by two sons and two daughters.

CONRAD G. DIETZ

Conrad G. Dietz, vice-president and general manager of the Aeronautical Corporation of America, Lunken Airport, Cincinnati, Ohio, died on September 12, 1931, as the result of an aeroplane accident. Mr. Dietz was born in Cincinnati on May 13, 1900, the son of Conrad and Margaretta Dietz. He attended the Asheville Preparatory School, Asheville, N.C., and was graduated from the Ohio Mechanics Institute in 1914.

The next six years were spent in traveling throughout the western part of the United States and operating an automobile sales and service agency in Cincinnati. For eight years, beginning in 1920, he had complete charge of all work at the Dietz Experimental Laboratories, Dayton, Ohio, of which he was president. He had been connected with the Aeronautical Corporation of America since 1928. His specialty was the design of aircraft and aircraft motors. Among the planes which he built at the Dietz Experimental Laboratories were a three-place biplane and a four-place biplane, both powered with a model E Hispano-Suiza motor, and a single-place racing biplane, powered with a Wright J5 motor. The Aeronautical Corporation of America, which was organized by Mr. Dietz, has developed and constructed a number of monoplanes, seaplanes, and motors.

Mr. Dietz became an associate member of the A.S.M.E. only a few months before his death. Surviving him are his widow, Harriet (Otte) Dietz, and two sons, Robert P. and James C. Dietz.

FRANK BUTLER DILTS

Frank Butler Dilts, lifelong resident of Fulton, N.Y., died at his home on September 17, 1931, after an illness of several months. Mr. Dilts was president of the Dilts' Machine Works, Fulton, manu-

facturers of paper mill machinery. He was also vice-president and director of the Citizen's National Bank & Trust Co., vice-president of the Draycott Paper Mills Co., Inc., and affiliated in an official capacity with the Arrowhead mills, all of Fulton.

Mr. Dilts was born on February 14, 1874. He received his early education in the Fulton schools and then took up the study of mechanical engineering at Cornell University. He left college in his junior year following the death of his father, Frank Dilts, then head of the Dilts Machine Works, Inc., and assumed active charge of the foundry and machine works. He was made president and treasurer in 1913. Mr. Dilts supervised the design work of the company, which included plans for new buildings and equipment, and water and electric power development. He laid out and arranged for the installation of machinery in paper mills, and was the first to conceive the idea of tempering paper mill beater roll bars and of using heat-treated alloy steels for this purpose. His company was also the first to market a bandless beater roll and a beater tub designed for a concrete base.

Mr. Dilts was a Republican and took an active interest in civic affairs in Fulton, serving as alderman of the Fourth ward from 1904 to 1907. He was also several years as officer of the Mount Adnah cemetery association. Mr. Dilts became a member of the A.S.M.E. in 1918.

His preference in sports was toward golf and he was a past-president of the Oswego country club and a member of the Onondaga golf and country club. During the World War, Mr. Dilts served as a Captain in the Ordnance Department and was stationed at the Watervliet Arsenal, Watervliet, N.Y. He served for some years as a member of the Fulton Hydraulic Race Commission, appointed by the Supreme Court, in connection with which his knowledge of engineering was applied to problems involved in the division of water among the various users of water power.

He is survived by his widow, Mrs. Bessie (Smith) Dilts.

ALVA CLYMER DINKEY

Alva Clymer Dinkey, president of The Midvale Company, died at his home in Wynnewood, Pa., on August 11, 1931.

He was born at Weatherly, Pa., on February 20, 1866, the son of Reuben and Elizabeth (Hamm) Dinkey, and attended the public schools of Weatherly and Braddock, Pa. In 1879, at the age of thirteen, he entered the Carnegie service as a water boy at the Edgar Thomson Steel Works, later serving as telegraph operator. In 1885 he became machinist for the Pittsburgh Locomotive Works and in 1888 expert machinist for the McTighe Electric Company, Pittsburgh.

He was appointed secretary to the superintendent of the Homestead Steel Works of the Carnegie Steel Company in 1889 and in 1893 was made electrician of the Homestead plant; in 1898 he became superintendent of the electric light and power plant. In 1899 he was appointed assistant general superintendent of the Homestead Steel Works, and in 1901, general superintendent.

In 1903, at the age of thirty-seven, Mr. Dinkey was elected president of the Carnegie Steel Company, retaining that position until 1915, when he resigned to assume the presidency of the newly formed Midvale Steel & Ordnance Co. When this latter company was sold, in 1923, to the Bethlehem Steel Corporation, he was elected president of The Midvale Company. He was a director of the Midvale Company, The Baldwin Locomotive Works, and the American Iron and Steel Institute.

Mr. Dinkey became a member of the A.S.M.E. in 1902. He also belonged to the American Institute of Electrical Engineers, the Society of Naval Architects and Marine Engineers, the Engineers Club of Philadelphia, the Engineers Society of Western Pennsylvania, the American Association for the Advancement of Science, and the Academy of Natural Sciences, as well as to many clubs in New York, Philadelphia, and Pittsburgh.

Surviving Mr. Dinkey are his widow, Margaret (Stewart) Dinkey, whom he married in 1891, two sons, and a daughter.

JOSEPH DOVE-SMITH

Joseph Dove-Smith, who died on March 25, 1931, was born at Newcastle-on-Tyne, England, on January 19, 1855. His parents were Joseph and Mary Ann (Asquith) Dove-Smith. He had a public school education and served an apprenticeship with Bolckow Vaughan & Co., iron and steel manufacturers. After experience as a fitter, turner, and draftsman with various engineering works, he became general foreman in 1885 of the Vulcan Iron Works, Winchester, England. He went to Manchester five years later as general foreman of Samuel Fisher & Co. In 1892 he accepted a position as general manager for John Holroyd & Co. in Manchester, where he remained for four years. He then went to Birmingham as works manager for Heenan and Froude. From 1898 to 1903 he was mechanical engineer for the London Rubber Company.

Mr. Dove-Smith left England for Canada in 1903 and for five years worked as a machinist, part of the time in charge of outside mechanical construction, for the Allis Chalmers Bullock Company, Montreal. He founded the firm of Dove-Smith & Son in 1908 at Niagara Falls to design and build special machinery and tools. During the World War the entire shop was devoted to the manufacture of master inspection gages for the Canadian and United States governments. He held patents in England for a rubber heel and in the United States and Canada for all-in-mesh transmission.

Mr. Dove-Smith became a member of the A.S.M.E. in 1918. He also belonged to the Society of American Military Engineers and was a director in 1924 of the Rotary Club. He was interested in all church work, especially small missions, and was an enthusiastic choral director of children. He is survived by his widow, Phoebe (Bell) Dove-Smith, whom he married in 1879, and by five daughters and a son.

ERVIN THAYER DRAKE, JR.

Ervin Thayer Drake, Jr., plant engineer for the Lever Bros. Co., Hammond, Ind., died on July 27, 1931. Mr. Drake was born on November 3, 1894, the son of Dr. E. T. Drake and Mary Aiken Drake, of Franklin, N.H. He attended the Cambridge (Mass.) Latin School and was graduated from Harvard University in 1916, with a B.S. degree.

Immediately following his graduation, he went to France and joined the Norton Hayes Ambulance Corps. He was discharged from the Army in the fall of 1919, with the rank of captain, and entered the soap plant of the Jones Bros. Tea Co. in Brooklyn, N.Y., for a six month's period of training in that buineass. He then secured a position as engineer with the Houchin-Aiken Company, Brooklyn, working on the design, construction, and installation of mechanical equipment for the production of soaps and allied materials. He also developed chemical processes for manufacturing soap, and equipment for the recovery of the by-products, especially crude and refined glycerine. In 1922 he laid out and supervised the construction of a complete soap plant and double-effect evaporators in Madrid, Spain. In 1923 he installed large crude glycerine evaporators in Havana, Cuba. During the next two years, he installed soap and glycerine plants at Middletown, Conn., Woonsocket, R.I., and Baltimore, Md. Later he was located at the plant of the company at Hawthorne, N.J.

When the Houchin-Aiken partnership was dissolved in 1926, Mr. Drake entered the employ of R. A. Keashey, New York, N.Y., selling commercial asbestos. He had been associated with the Lever Bros. Co. since February, 1928. He acted as construction engineer on the Hammond plant of the company, and during the last year of his life had served as plant engineer.

Mr. Drake became a junior member of the A.S.M.E. in 1923 and an associate of the Society two years later. He is survived by his widow, formerly Elizabeth K. Lum, of Chatham, N.H., whom he married in 1921, and by three sons, E. T. Drake, III, and Charles Lum and Herrick Aiken Drake.

THOMAS ALVA EDISON

Thomas Alva Edison was born at Milan, Ohio, on February 11, 1847. On the paternal side he was descended from John Edison, who came to New York from Holland in 1728. His great-grandfather, Thomas Edison, was a banker, and signed the Continental currency in 1778. John Edison went to Canada in 1783 and his son, Samuel, father of Thomas Alva Edison, was born at Digby, Nova Scotia, in 1804. He married Nancy Elliott in 1828 and they lived in Canada until 1838, when he became involved in the Papineau rebellion and found it necessary to leave the country. They came to the United States and in 1842 settled at Milan.

Thomas Edison's mother was a native of New England and had taught school in Canada prior to her marriage. Largely to her he owed his early education. She took him out of school, where he was considered stupid and stood at the foot of his class, and not only succeeded in developing a love of study and reading but also encouraged him in the experimental work which then, as always, was his chief interest.

These early experiments of Edison's were for the most part of a chemical nature, and throughout his life he retained his love for chemical research, though circumstances directed so large a part of his effort into the electrical field.

The Edison family, it is pointed out in the biography of his life by Dyer and Martin, one of the most authoritative works, while not

rich, were in comfortable circumstances. It was not to support himself that Edison became a newsboy at the age of twelve, but to earn additional pocket-money with which to purchase materials for his experiments. The family had moved to Port Huron, Mich., in 1854, and finally securing the consent of his parents, Edison applied, in 1859, for the privilege of selling newspapers on the trains of the Grand Trunk Railroad, between Port Huron and Detroit.

The details of these early years need not be recorded here. Selling newspapers, books, candy, and fruit gave Edison what money he required for experimenting. He set up a laboratory in the baggage car of the train, and all of his leisure time was spent there and in the Detroit public library, where he read many books and magazines otherwise inaccessible to him. During the early days of the Civil War he further increased his revenues and experience by issuing a small newspaper, for which he wrote the copy and set the type, and which was printed on a handpress in the baggage car.

During this period Edison had also become interested in telegraphy and to this he turned when a fire in his train laboratory one day led to his abrupt ejection on the Mount Clemens platform, with his entire outfit. The station agent there, whose child Edison had rescued from the path of a train, had already taught him train telegraphy, and this experience enabled him to secure the post of operator at Port Huron. Subsequently, he applied for a job as night operator for the Grand Trunk at Stratford Junction, Canada, and in the cellar below that office he spent nearly all his time in chemical experiments and in reading. It was at Stratford, in 1863, that he made his first invention—a device to send automatically the hourly signals which he was required to make to the central office to show that he was on duty. This device, until detected, permitted him to remain in his workshop uninterruptedly!

Records of the next five years show Edison to have been a roving operator in various western and southern cities, including Toledo, Indianapolis, Cincinnati, Louisville, Memphis, and New Orleans. He worked on night shifts whenever possible, as that arrangement gave him more time and freedom for experiments and reading. He developed unusual speed and accuracy as an operator and frequently made improvements in the equipment which he used. One of his first important inventions was a repeating instrument which permitted a message to be transmitted automatically on a second line without the presence of an operator.

Edison's restlessness led him East in 1868. A friend in Boston helped him to secure a night line with the Western Union, where his speed and general ability were soon recognized. He established a small workshop and spent the most of his salary on books and apparatus. He applied for his first patent in October of that year, to cover a device by means of which the votes of a large number of people might be recorded in a few minutes.

It was in Boston also that Edison invented his first stock ticker and started a ticker service. He visited New York during the latter part of 1868 in an unsuccessful attempt to sell the ticker machine. Later he developed a duplex telegraph which he took to Rochester, N.Y., to test out on the lines of the Atlantic & Pacific Telegraph between that city and New York. He was unsuccessful in this also and in 1869 went to New York, leaving behind him because of debts what few instruments and books he possessed.

Transition within a few days from this impoverished state to a position earning $300 a month was the result of his understanding of ticker apparatus. While waiting to secure a position as operator with the Western Union, Edison took the opportunity to study the central transmitter in the office of the Gold & Stock Telegraph Co. and happened to be present at the time of a breakdown in service and was able to detect the cause of the trouble. This evidence of his ability led to the offer of a position as superintendent of the entire plant.

Before the end of the year Edison had associated himself with Franklin L. Pope in a "Bureau of Electrical and Telegraphic Engineering." In a small shop in Jersey City he followed up his work on telegraph printers, devising a printer to print gold quotations instead of indicating them. This was sold to the Gold & Stock Telegraph Co., which also took over private telegraph lines which were established by Pope, Edison, and J. N. Ashley, who had become a partner in the firm.

Edison was now definitely launched upon that period of his career so productive that the Commissioner of Patents said, "There is a young man in New Jersey who has made the path to the Patent Office hot." The development and manufacture of stock tickers for the Gold & Stock Telegraph Co. necessitated the establishment of several shops in Newark and the employment of about 300 men. Before he was thirty years old Edison had also perfected the alignment of letters on what is now the Remington typewriter, made many contributions to the development of automatic, duplex, and quadruplex telegraphy, and invented the mimeograph.

On December 25, 1871, Edison married Miss Mary G. Stillwell, and in 1876 they went to live at Menlo Park, N.J., where he established a new laboratory such as he had long desired. Out of this laboratory and adjoining workshops during the next ten years came the carbon transmitter for the telephone in 1876, the phonograph in 1877, the incandescent lamp in 1879, the discovery of the "Edison effect," the fundamental principle on which the radio tube is based, in 1883, and many other inventions of importance.

Concerning the incandescent lamp Dr. Frank B. Jewett wrote as follows in *Science* (January 15, 1932): "For Edison the incandescent lamp was but an incident. . . . As an inventor and experimentalist he had produced an ingenious and potentially valuable illuminating device, but the electrical art of 1879 was almost devoid of the things to make it commercially available. Seldom has the creator of so perfect a new tool found the field so bare. More seldom still has one done so much to create an art around and for his tool as Edison did in the ten years following 1879.

"Generators, systems of distribution and utilization, switchboards, auxiliary equipment and adjunct devices, large and small, in vast profusion flowed unceasingly from Edison and the group of intelligent young men with whom he surrounded himself. In the welter of this torrent of new things no one will probably ever know just who was initially responsible for each and every one of them. Three things are certain, however: first, Edison himself was the creator of the principal items; second, his was at all times the guiding mind and the driving force; third, the group of men who later came to be known as Edison Pioneers, and who were and in large measure still are dominating factors in the electric light and power industry, were youths of his discerning selection."

The first Mrs. Edison died in 1884, leaving him three children, Marion Estelle, Thomas Alva, Jr., and William Leslie. He was married a second time in 1886, to Miss Mina Miller, and in 1887 established a new and more elaborate laboratory in Orange, N.J., where all his later work was done. Much of this work, which brought the record of his inventions at the Patent Office to more than 1200, related to the application of his earlier inventions. There were several other outstanding achievements, however, which should be mentioned in even a brief record. These include the motion picture camera, patented in 1891, and the kinetophone, patented in 1912, and his contributions to the portland cement industry and to the development of storage batteries.

During the World War Edison turned all his energy to work for the Naval Consulting Board, of which he was made president in 1915. He and his associates worked on many problems which again, after many years, gave him an opportunity to work with chemicals. The manufacture of carbolic acid and aniline dyes, and the perfection of many devices for the Navy, made his services of tremendous value to the country.

It was during the War that Mr. Edison became interested in the rubber supply of the United States, and his research work during the last few years of his life dealt largely with that problem.

With Mr. Edison at the time of his death on October 18, 1931, at his home in Llewellyn Park, West Orange, were Mrs. Edison and their three children, Charles, Madeline, and Theodore, as well as the three children by his former marriage. Much of the tranquillity of the latter years of his life was due to the care of Mrs. Edison, whose voice was the only one able to pierce the deafness which had afflicted him for many years.

Edison's achievements were recognized in many honors bestowed upon him. Among these were the Rathenau Medal from Germany, the John Fritz Medal in 1908, and the Congressional Medal in 1928; three degrees of the Legion of Honor of France—Chevalier, Officier, and Commander; honorary degrees of Ph.D. and D.Sc. from Rutgers College, Ph.D. from Union College, D.Sc. from Princeton University, and LL.D. from the University of the State of New York; and honorary memberships in The American Society of Mechanical Engineers (in 1904) and in the American Society of Civil Engineers and the Engineers' Club, New York. He became a member of the A.S.M.E. in 1880, was a Founder Member of the American Institute of Electrical Engineers, and also belonged to the American Institute of Mining and Metallurgical Engineers.

Again and again in the tributes to Mr. Edison following his death his characteristics as an inventor and as a man are brought out:

"Mr. Edison became a great man by virtue of three moral qualities—indomitable courage, keen intelligence, and the will to serve. Widely as his mind ranged, he had the rare power of focusing it on the question in hand and sticking to it till he reached a solution."

"Edison was by far the most successful and, probably, the last exponent of the purely empirical method of investigation. Everything he achieved was the result of persistent trials and experiments often performed at random but always attesting extraordinary vigor and resource. Starting from a few known elements, he would make

their combinations and permutations, tabulate them and run through the whole list, completing test after test with incredible rapidity until he obtained a clue. His mind was dominated by but one idea, to leave no stone unturned, to exhaust every possibility."

"His place is assured as one of the world's greatest benefactors, for the results of his inventive genius have contributed immeasurably to the advancement, comfort, and happiness of mankind. But aside from the splendor of his achievements, the teachings of his life, his tireless pursuit of scientific truth, his all-embracing thoroughness in research, his intelligence, energy, and persistency in dealing with the mighty problems that engaged his eager interest, constitute a legacy of priceless value to the youth of all lands."

VICTOR EVERETT EDWARDS

Victor Everett Edwards, whose invention of flying shears permitted continuous rolling of steel rods, died at his home in West Boylston, Mass., on May 16, 1931. Illness necessitated his retirement in 1928 from the Morgan Construction Company, Worcester, Mass., of which he was vice-president, chief engineer, and director.

Victor Edwards was born at North Chelmsford, Mass., on September 4, 1862, the son of Dr. Nathan Brown and Sibbyl Robbins (Hutchins) Edwards. He attended the North Chelmsford school and was graduated from the Worcester Polytechnic Institute in 1883 with a B.S. degree. In 1927 the Institute conferred the degree of doctor of engineering upon him.

During the seven years following his graduation Mr. Edwards acquired knowledge of motive power and the design of heavy machinery through association with a number of companies. He was first connected with the Merrimack Manufacturing Company, Lowell, Mass., and then with the Deane Steam Pump Company, Holyoke, Mass. He spent about two years with the Washburn & Moen Mfg. Co., Worcester, working on economy testing of engines and boilers part of the time. For about six months he studied water-wheel settings for the Holyoke Machine Company, Worcester. He was in the employ of the Simonds Rolling Machine Company, Fitchburg, Mass., for two and one-half years, setting up and taking charge of their Canadian shop for part of the time, and being assistant superintendent for the company at Fitchburg during the remainder of it. He also served as draftsman for the Otis Steel Co., Ltd., Cleveland, for a period of six months, and assisted Edward Sawyer, of Boston, for a short time.

In 1890 Mr. Edwards accepted a position as chief engineer for the Morgan Construction Company and was elected vice-president the following year. He was also a director of the Massachusetts Mutual Life Insurance Company and had served as a trustee of Worcester Polytechnic Institute. During the World War he was commissioned a major in the U. S. Ordnance Department, being stationed at Washington and the Aberdeen Proving Grounds.

Mr. Edwards held more than one hundred United States and foreign patents, dealing for the most part with the manufacture of steel. The most important of these, the flying shears, were designed to travel along with the hot rods as they emerged from the rolls and cut them while in motion. This device, eliminating the time and expense of stopping the rods for cutting, effected a great saving in the cost of their manufacture. As a hobby Mr. Edwards designed sun-dials.

Mr. Edwards became a junior member of the A.S.M.E. in 1889 and participated in the European trip of the Society that summer. He became a member in full the following year. He was also a member of the American Institute of Mining and Metallurgical Engineers and the American Iron and Steel Institute. His clubs included the Engineers' in New York and Duquesne in Pittsburgh, Pa. He was a member and formerly a trustee of the West Boylston Congregational Church.

Surviving Mr. Edwards are his widow, formerly Janet Gage, of Skowhegan, Me., whom he married in 1896, a son, Kenneth Gage, and a daughter, Ruth Edwards.

HUGH MacDONALD ELDER

Hugh MacDonald Elder died on July 30, 1931, at his home in Fairlie, Ayrshire, Scotland, where he had been since 1927.

Mr. Elder was born on October 21, 1865, the son of George and Jane (MacDonald) Elder. He served an apprenticeship with Alley & McLellan, engineers, boilermakers, and shipbuilders, at their Sentinel Works in Glasgow. He then spent four years in technical studies at the London and City Guilds which granted him a certificate in mechanical engineering in 1890.

For a short time, following the completion of his technical education, Mr. Elder was in charge of an experimental electric light station, at Cathchart, near Glasgow. From then until 1904, with the exception of some time spent in the West Indies and Central America, he was engaged in marine engineering, securing both British and American certificates. His work in the West Indies was as master mechanic of railway shops for the San Domingo Improvement Company, Puerto Plata, San Domingo, and in Central America as contracting consulting engineer, constructing and rebuilding sugar mills, refrigerating plants, pumping machinery, etc., in Guatemala.

In the summer of 1904 he became assistant to the superintendent of the Inspection Department of the Casualty Company of America. In 1907 he was appointed chief engineer for the Trinity Building in New York and two years later took a similar position in the Abraham & Strauss and Simpson Crawford Company stores.

In 1911 Mr. Elder began a connection of more than fifteen years with the American Locomotive Company. He had charge of the power departments in various plants in the United States and in Canada until 1920, when he was transferred to the New York office. In 1924 he was made superintendent of power plants for the company.

Mr. Elder became a member of the A.S.M.E. in 1912. He is survived by his widow, Mary S. (Common) Elder, whom he married in 1904.

HARRINGTON EMERSON

Harrington Emerson, who died in New York, N.Y., on May 23, 1931, is recognized as a pioneer in the popularization of scientific management. Under the term "efficiency" he applied its principles in 1904 to the problems of the Santa Fé Railroad, in a form which caught the public imagination. He defined efficiency as "the elimination of all needless wastes, in material, in labor, and in equipment, so as to reduce costs, increase profits, and raise wages." He applied his theory to a wide variety of industries with startling results, bringing about standardization, cost control, and waste elimination. He met with no serious opposition from employees because he maintained that no improvement could be made permanent unless it helped the employee as well as the employer. He placed increasing emphasis, as the years passed, upon the personal side of efficiency. His ideals for the workman were summarized as follows in his book entitled "The Twelve Principles of Efficiency:" "Let each man work with the reliability of a steam valve, yet with the joy of a hunting dog and the inspiration of the artist." It was this spirit of a crusader and a moralist, together with a keen appreciation of the commercial opportunities presented by the movement, which gave him so large a following.

Harrington Emerson was born on August 2, 1853, at Trenton, N.J., the son of the Rev. Edwin Emerson, a Presbyterian preacher and educator, and Mary Louise (Ingham) Emerson. When he was nine years old the family went abroad in order that the children might be educated there. Harrington Emerson grew up with tutors and in schools in Greece, France, Italy, Germany, England, Switzerland, and Austria. He received an M.A. degree from the Royal Bavarian Polytechnic at Munich, where he was a classmate of the inventor of the Diesel engine.

When Mr. Emerson returned to the United States in 1876, at the age of twenty-three, he was given the chair of modern languages and literature at the University of Nebraska. Subsequently he was appointed registrar and secretary of the faculty. He taught at the university for six years, during which time he was active in developing the institution along more efficient lines.

Between 1882 and 1900, when he established a consulting office in New York, Mr. Emerson built the background for the work which he carried on during the remainder of his life. As a real estate dealer in the Middle West he acquired both wealth and a knowledge of the frontier of that day which led to his appointment as a member of the staff of the general manager of the Chicago, Burlington, and Quincy Railroad. The selection of town sites, excursions of settlers, prospects of coal mines, crop failures, and other problems relating to the extension of the frontier were turned over to him during the several years he served the road.

After about ten years in frontier and railroad life Mr. Emerson consented to act as representative of a British syndicate seeking American investments. In this connection he investigated many mills, factories, and mines in the United States, Mexico, and Canada, and began to discover the causes and remedies of failure. This work, perhaps more than any other, laid the basis for his principles of efficiency.

With the discovery of gold in Alaska Mr. Emerson interested himself in the problems of transportation and communication involved. He spent some time in the Yukon, driving dog sleds himself and studying the conditions of the country. He was instrumental in placing in service the first United States mail routes in Alaska, opening the line for both summer and winter delivery from Juneau to St. Michael. He made a report on the northern submarine cable route to Asia

which was largely followed by the United States War Department in laying its Alaskan cables.

Mr. Emerson had already achieved considerable success in discovering and eliminating wastes and losses in industrial plants and transportation enterprises when he was called to Atchison in 1904 at the time of the machinists' strike on the Santa Fé road. The problem was four-fold: to continue the repair and renewals of the rolling-stock and motive power in spite of the strike; to take care of a sudden 40 per cent increase in business without new shops or equipment; to establish friendly relations between employer and employee where there had been dissatisfaction and unrest for a long time; and, although of less importance, to decrease unit costs. Even though his system was still in its formative stage Emerson made recommendations which were successfully carried out. Not only that, but his principles of efficiency, brought before the public in connection with this job, created wide interest. To handle consulting work of increasing scope and importance Emerson organized a group of associates, The Emerson Engineers, who under his guidance have made contributions of inestimable value to the development of scientific management. He withdrew from active association with the organization about five years before his death.

Emerson's work extended to many countries. During recent years he had served as counselor to the Ministry of Railroads of the National Government of China and had been called in consultation by Japan, Poland, Czechoslovakia, and South American governments. In 1930 he was preparing reports on unemployment for departments of the French and Canadian governments. He had but recently come home from Russia where he was advisor to the Soviet government regarding its contemplated continental railroad system, and was planning to return for further work.

His success in the elimination of waste led to his appointment in 1921 as a member of the Committee on the Elimination of Waste in Industry, called together by Herbert Hoover when he was president of the Federated American Engineering Societies.

The principles of efficiency for which he stood were set forth by Emerson in book form in 1909 in "Efficiency as a Basis for Operation and Wages," and in 1912 in "The Twelve Principles of Efficiency." His "Lessons in Personal Efficiency" have been widely studied and his magazine articles and lectures before scientific organizations were numerous.

The technical societies of which Emerson was a member were many. He joined the A.S.M.E., of which Taylor and Gantt, and later Gilbreth, were fellow members, in 1899. He belonged to the American Institute of Mining and Metallurgical Engineers and was keenly interested in problems of over-production in the mineral industry. The American Electrochemical Society, The American Economic Association, the American Electric Railway Association, the Society of Industrial Engineers, and The Franklin Institute in this country, as well as the Société des Ingénieurs Civils de France, the Verein deutscher Ingenieure, and Polish and Czechoslovakian engineering societies, had all been honored by his membership.

At a notable testimonial dinner in Washington in October, 1930, a group of his associates recognized his achievements by presenting the Society of Industrial Engineers with a plaque designated the Harrington Emerson Trophy, to serve as an annual chapter award of the society.

What Harrington Emerson achieved and those qualities which underlay his success were summarized by Edward J. Mehren in the June, 1931, issue of *Factory and Industrial Management*, as follows:

"He made a full contribution to the art of management. His brilliant powers of analysis, his resourcefulness, his ability to cut through precedent led him to original solutions and marked him a great engineer. Much of his technique, though necessarily changing with conditions, remains a permanent asset in the literature of management.

"But conspicuous as was his engineering achievement, his work as teacher and philosopher will probably stand as his greatest contribution. He had been a college professor. He knew how to clarify and present ideas; he knew how to draw analogy. And that is just what he did—and did brilliantly—for the developing art of management. He carried its lessons to every corner of the industrial world, here and overseas.

"His success as teacher—as publicist of the management movement—was grounded deep. For he was a philosopher. He was interested in fundamental causes. He sought always the principles involved. His twelve principles of efficiency stand today a conspicuous expression of the philosophy of management."

DWIGHT HALL FAULKNER

Dwight Hall Faulkner was born at Ashtabula, Ohio, on September 16, 1895, the son of John C. and Mary H. Faulkner. He studied at the Manual Training High School in Brooklyn from 1909 to 1913 and then entered the Sheffield Scientific School of Yale University which granted him a Ph.B. degree.

During the World War Mr. Faulkner was senior inspector of aviation engines in the Signal Corps of the United States Army. After leaving the service he accepted a position in 1919 as an erecting engineer of the Bethlehem Steel Corporation, Bethlehem, Pa. Later he did similar work for the McIntosh-Seymour Corporation, Auburn, N.Y., and in 1920 and 1921 was research industrial engineer for the Yale & Towne Mfg. Co., Stamford, Conn. In 1921 he became sales engineer for the H. B. Smith Co., New York, the position which he held at the time of his death. He was also president of the Dissolene Corporation of Hempstead, Long Island, N.Y.

Mr. Faulkner became a junior member of the A.S.M.E. in 1921 and was promoted to the grade of an associate member in 1926. He also belonged to the American Society of Heating and Ventilating Engineers, the Yale Club and Yale Engineering Society, and was vice-president of the Anthracite Coal Club. He married Ruth Anderson in 1925 and is survived by her and two children. His death occurred in Brooklyn on February 8, 1931.

HENRY B. FITZPATRICK

Henry B. Fitzpatrick, who in 1930 became a junior member of the A.S.M.E., was born in Honolulu, Hawaii, on June 18, 1904, the son of C. H. and Alice (Brady) Fitzpatrick. He was educated in the high school at Newberg, Ore., and at the Oregon State College, from which he received a B.S. degree in 1929.

After a short time with the Bend Iron Works, Bend, Ore., he entered the employ of the Byron Jackson Company as a machinist. At the time of his death, on March 23, 1931, he was a salesman for that company.

BRUCE FORD

Bruce Ford, second vice-president and a director of The Electric Storage Battery Company, Philadelphia, Pa., and until recently general manager of the company, died on August 10, 1931, at his home at Chestnut Hill, Philadelphia, after a brief illness following several years of poor health. Mr. Ford was also a director of the Chloride Electrical Storage Company, Ltd., of Manchester, England.

Mr. Ford was born in Brooklyn, N.Y., the son of Edward Lloyd and Lucenia (Young) Ford, and was educated at St. Paul's School, Garden City, L.I., and Brooklyn Polytechnic Institute. Later he took evening courses at The Franklin Institute for a year. He served an apprenticeship and worked in the drafting room of the United Electric Improvement Company and the Heisler Electric Company, of Gloucester, N.J., and was employed for six years by the Johnson Company (subsequently the Lorain Steel Company), of Johnstown, Pa., as draftsman, shop foreman, and engineer. During the last year of his connection with this company he developed and installed a contact railway system in Washington, D.C.

In 1899 Mr. Ford became engineer in charge of development and design in The Electric Storage Battery Company and was promoted to the office of vice-president in charge of technical development in 1913. He had to his credit more than fifty inventions in the storage battery field, the patents being owned by the company.

Mr. Ford was elected a member of the A.S.M.E. in 1907. He also belonged to the Society of Automotive Engineers, the American Institute of Electrical Engineers, and The Franklin Institute, as well as to a number of clubs including the Engineers' of New York and Philadelphia, and the Philadelphia Cricket and Old Colony. He inherited membership in the Military Order of the Loyal Legion of the United States from his father, who was a captain in the Union Army during the Civil War. Mr. Ford was a vestryman of St. Paul's Church, in Chestnut Hill. He was an enthusiastic fisherman and big-game hunter and had secured many trophies during hunting trips in Canada. He is survived by his widow, Sophie (du Pont) Ford, formerly of Wilmington.

G. CLINTON GARDNER, JR.

G. Clinton Gardner, Jr., died suddenly of heart failure at Kane, Pa., on June 9, 1931. He is survived by his widow, Elizabeth (Stirling) Gardner, and by two sons, G. Clinton Gardner, 3d, and John McLean Gardner, of Erie, Pa.

Mr. Gardner was born at Altoona, Pa., on March 5, 1873. His father was general superintendent of the Pennsylvania Railroad, so that the natural thing for the son to do, after attending Hill School, Pottstown, Pa., was to enter the shops of that road. He served a special apprenticeship as a machinist and worked as draftsman and inspector in shops at Altoona, Renovo, West Philadelphia, and Jersey

City. In 1902 he was appointed assistant road foreman of engines on the New York Division of the United Railroad of New Jersey a branch of the Pennsylvania Railroad. He had served as general foreman of the Belvidere Division, Lambertville, N.J., Hudson Division, Jersey City, N.J., and Manhattan Division, also with headquarters at Jersey City. For several years he was stationed at Buffalo, N.Y., as assistant engineer of motive power, and then was promoted to the Monongahela Division at Uniontown, Pa., as master mechanic. At the time of his death he was master mechanic of the Renovo Division, with offices at Erie.

Mr. Gardner had been a member of the A.S.M.E. since 1903.

ADOLPH A. GATHEMAN

Adolph A. Gatheman, whose death occurred at the Naval Hospital, Chelsea, Mass., on June 12, 1931, was born at Oldenburg, Germany, on May 4, 1880. His parents, Ludwig and Amalia (Dinklage) Gatheman, brought him to the United States in 1882 and apprenticed him at the age of fourteen to the machinist's trade in Chicago, where he worked at that trade for some years.

At the outbreak of the Spanish-American War, Mr. Gatheman entered the United States Navy and was soon rated as a first-class machinist. He was commissioned chief machinist in 1901, in charge of engineer's departments of different ships. For about a year he was chief engineer of the U.S.S. *Isle de Cuba* and at other periods was stationed at the public works office of the Boston Navy Yard and was an inspector of coal at Baltimore, Md. In 1917 he was commissioned a lieutenant and as assistant to the engineer's office of the Boston Navy Yard was put in charge of repairs and maintenance of the Boston section of the patrol fleet.

He resigned from the navy in 1919 to accept an appointment as supervisory engineer of the Sea Service Bureau of the U. S. Shipping Board. He was in active charge of training engineers on Shipping Board vessels and established schools at the General Electric Company, Schenectady, N.Y., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa., and McIntosh & Seymour Corp., Auburn, N.Y., for training engineers on turbine reduction gears, electric drive, and Diesel engines. Subsequently he served as port engineer of the New England district of the Shipping Board, making his headquarters at Boston.

Since his resignation from the Board in 1922 Mr. Gatheman had been connected with the sales work of the A. M. Byers Co., Pittsburgh, acting as district manager of New England.

Mr. Gatheman became a member of the A.S.M.E. in 1923. He also belonged to the Society of Naval Architects and Marine Engineers, New England Water Works Association, New England Gas Association, New England Railroad Club, Engineering Societies of Boston, National Association of Practical Refrigerating Engineers, Engineer Club of Boston, as well as several clubs, the American Legion, and the Masonic fraternity. He is survived by his widow, Mabel S. (Obrion) Gatheman, of Boston.

E. FENTON GILBERT

E. Fenton Gilbert, president of The Dampney Company of America, of Boston, Mass., died at his summer home on Cape Cod on August 29, 1931. He was born in Jamestown, N.Y., on June 11, 1886, the son of Albert and Jeannette (Fenton) Gilbert. He was a graduate of Hill School at Pottstown, Pa., and received his technical education at the Sheffield Scientific School of Yale University.

Mr. Gilbert entered the employ of the Art Metal Construction Company of Jamestown, N.Y., in 1907 and was its secretary-treasurer and general manager when he left the company seven years later. He was next identified for a year with the Miami Motor Cycle Company of Middletown, Ohio, as manager of its motorcycle department. For the next two years, he was New England manager of the Toledo Scale Company, of Toledo, Ohio.

During the World War, Mr. Gilbert served in the United States Naval Reserve Corps, being connected with the Aircraft Division of the Bureau of Ordnance, in charge of the production of aircraft armament. Following the war, he operated an independent sales agency in Boston, representing managers of factory equipment. In 1920 he secured a financial interest in The Dampney Company of America. He had been its treasurer and president since that time. This company manufactures protective coatings for metal surfaces, used extensively in power plants.

Mr. Gilbert was a member of several clubs and societies, including the Yale Club of New York, the University Club of Boston, and the A.S.M.E., which he joined as an associate in 1924. Surviving Mr. Gilbert are his widow, Katharine L. (Gifford) Gilbert, Brookline, Mass., whom he married in 1912, and two children, John A. and May Gilbert.

WILLIAM A. GILCHRIST

William A. Gilchrist, who died on December 18, 1930, was born at Alpena, Mich., on October 17, 1875. He attended the University of Michigan and secured some practical experience in the woodworking industry and in transportation on the Great Lakes. From 1899 to 1902 he engaged in construction and operation for the Saginaw Sugar Company and Michigan Sugar Company, manufacturers of beet sugar. During the next few years he worked on construction and repairs of ocean-going steamers. Then for twenty years he was associated in executive capacities with companies handling the design, construction, and operation of forest products plants. At the time of his death he was president of Gilchrist and Company, of Chicago, Ill.

Mr. Gilchrist became a member of the A.S.M.E. in 1922. He was also chairman of a committee in charge of research work for the National Lumber Manufacturing Association at that time.

EDWARD JOHN GOTTSCHALK

Edward John Gottschalk, whose death from diabetes occurred on June 21, 1931, at the Nassau Hospital, Mineola, N.Y., was born at Rockland, Maine, on July 22, 1898. His high school education was obtained at the De Witt-Clinton High School in New York. He subsequently attended classes at Cooper Union and Pratt Institute, being graduated from the mechanical engineering course of the latter in 1920. From then until 1927 he worked as mechanical draftsman for the American Manufacturing Company, in Brooklyn. He designed textile mills and machinery, made power plant layouts and planned the conversion from steam to electric drive at the Charleston, S.C., plant of the company, redesigned the heating system at the Brooklyn mill, prepared the layout for a Philadelphia mill manufacturing jute carpet yarn and jute twines, and assisted in the construction of a mill at Calcutta, India, for the manufacture of jute bagging for use in cotton mills. During the next year he was connected with the E. Y. Sayer Engineering Corporation in New York. From then until his death he was with the Pan American Petroleum & Transport Co. as mechanical engineer.

Mr. Gottschalk belonged to the United States Naval Air Service, 1917–1918, being stationed at the Rockaway Naval Air Station, Long Island. He became an associate member of the A.S.M.E. in 1926. He also belonged to the Masonic fraternity.

THOMAS WILBRAHAM GREEN

Thomas Wilbraham Green, president and treasurer of the Thos. W. Green Engineering Co., Philadelphia, Pa., died on January 6, 1930. He had been a member of the A.S.M.E. since 1902.

Mr. Green was born at Clay Cross, Derbyshire, England, on July 3, 1853. His technical training was secured in the United States. He served an apprenticeship with Wilbraham Brothers, of Philadelphia, from 1869 to 1873 and worked for that company as designer and patternmaker for many years. The name of the company was changed to the Wilbraham Baker Blower Company and later it became the Wilbraham Green Blower Company and relocated in Pottstown, Pa. Mr. Green advanced to the position of chief engineer of the company and also served as its secretary and treasurer. He designed and built the Green pressure blowers, pumps, exhausters, etc.

In 1914 Mr. Green located in Trenton, N.J., and did consulting work there and in Philadelphia. Subsequently he organized the Thos. W. Green Engineering Co.

JOHN GOTTFRIED GUSTAFSON

John Gottfried Gustafson, chief mechanical engineer in the Door Device and Signal Department of the Otis Elevator Company, New York, N.Y., and the inventor of many devices used on elevator doors, died on March 20, 1931, of heart disease at his home in Teaneck, N.J.

Mr. Gustafson was born in New York on May 10, 1893, the son of J. Aaron and Ida C. Gustafson. At the age of eighteen he entered the employ of the Burdett Rowntree Manufacturing Company, New York, designing electric dumbwaiters, pneumatic doors, operating and elevator interlocking engines, and manually operated door and steel devices for street railway cars. He had two years' shop work for this company and spent some time collecting field data and checking outside construction work. From 1917 to 1922 he was engaged in the same sort of work for the Elevator Supplies Co., Inc., Hoboken, N.J., successor to the Burdett Rowntree Manufacturing Company. He also worked upon signal apparatus for elevators, hydraulic hoisting machinery for theater curtains, and electric

magnetic operating devices for elevator hatchway doors. From 1919 to 1922 he was in charge of the special mechanical equipment division of the engineering department of the company.

From 1922 until he became identified with the Otis Elevator Company in 1930 Mr. Gustafson was in charge of the mechanical engineering department of the Graham & Norton Co., Inc., New York.

Mr. Gustafson became a junior member of the A.S.M.E. in 1919 and an associate member in 1925. He also belonged to the Swedish-Norwegian Society of New York and to the Masonic fraternity.

Surviving Mr. Gustafson are his widow, Mrs. Hjordis (Nelson) Gustafson, and their daughter, Phoebe Justine Gustafson.

WILLIAM JOSEPH HAGMAN

William Joseph Hagman was killed as the result of a fall down an elevator shaft at the Eddystone plant of the Baldwin Southwark Corporation, on April 6, 1931.

Mr. Hagman was born at Philadelphia, Pa., on March 23, 1866, the son of Frederick W. and Mary L. (Miles) Hagman. He attended the Central High School in Philadelphia and Lehigh University, and served an apprenticeship as machinist and draftsman for Bement, Miles & Co., Philadelphia, later known as the Niles-Bement-Pond Company, and remained with them until 1925, becoming assistant chief draftsman in 1894, chief draftsman in 1897, and general manager in 1900. He then accepted a position as consulting engineer for the Southwark Machine Company, South Philadelphia. Since its consolidation in 1930 with the Baldwin Locomotive Works, under the name of the Baldwin Southwark Corporation, he had been located at its plant at Eddystone, Pa. At the time of his death he was also vice-president of the Ridgway Machine Company, Ridgway, Pa.

Mr. Hagman became a member of the A.S.M.E. in 1901. He also belonged to the Academy of Arts, the Union League, the Art Club, and the Engineers Club of Philadelphia. He was keenly interested in paintings and engravings. One daughter, Mrs. Newton B. Misell, New York, survives him.

ARTHUR GOODWIN HALL

Arthur Goodwin Hall, who died on August 22, 1930, at his home in Cincinnati, was born at Newport, Ky., on August 11, 1873. His parents were Thomas J. and Anna Theresa (Neighbors) Hall. Prior to his two years at the University of Michigan, Mr. Hall was in the employ of the Cincinnati Traction Company, which he served for seven years as fireman, oiler, dynamo tender, and engineer. After leaving the University of Michigan in 1898, he worked for a year as chief engineer for the Gerke Brewing Company of Cincinnati. The following year he was a lecturer for the International Correspondence Schools.

In 1900 Mr. Hall went to Columbus to work as chief engineer at the Chittenden Hotel. After two years there he accepted the position of chief electrician for The Hoste Brewing Company of Columbus and subsequently worked as chief engineer for the Smith Agricultural Chemical Company of that city. From 1904 to 1907 he was chief engineer of the Wehrle Company, stove manufacturers of Newark, Ohio. He then spent a year each as manager for the Nelsonville (Ohio) Electric Light Company, chief engineer of The Hocking Valley Railway Company, factory superintendent for F. W. Niebling & Co., manufacturers of ice and refrigerating machinery in Cincinnati and superintendent of The Oliver Schlemmer Heating & Power Co. of that city. In 1912 he was employed by the City of Cincinnati as chief smoke inspector and during the next four years was mechanical director of the City of Cincinnati General Hospital. After a year in consulting work he took the position of combustion engineer with the Procter & Gamble Co., which he retained until 1921. From then until his retirement in 1924 he was chief engineer of the Emery Candle Company, Cincinnati.

Mr. Hall became a member of the A.S.M.E. in 1913 and was also active in the National Association of Power Engineers. He belonged to the Masonic fraternity and to the Elks. He is survived by his widow, Ella (Carson) Hall, and by two married daughters.

STEPHEN STOCKING HALL

Stephen Stocking Hall, former president and, at the time of his death on September 8, 1931, chairman of the Board of Directors of The Pickering Governor Company, Portland, Conn., was born in that city in January 18, 1864. He was the son of Jesse and Clara E. Hall. He obtained his early education at the Seabury Institute and the High School there, and began work for The Pickering Governor Company in 1881. He had been active in the conduct of its affairs until within a few years of his death. He held patents for various attachments for governors, including a device for the transmission of linear motion, and a patent for universal joints.

Mr. Hall had been a member of the A.S.M.E. since 1912. He is survived by his widow, Marie E. (Pascall) Hall.

WILLIS EDWARD HALL

Willis Edward Hall, whose death occurred on July 25, 1931, at Skytop, Pa. was born in Philadelphia, Pa., on July 20, 1860, the son of John Augustus R. and Caroline (Alford) Hall. He was given a B.S. degree by the Towne Scientific School of the University of Pennsylvania in 1881, and an M.E. degree two years later. Following his graduation, he spent a year in the design department of the Baldwin Locomotive Works. He then served an apprenticeship with the Pennsylvania Railroad, at the Altoona shops, and was subsequently made assistant master mechanic there. From 1892 to 1902, he was assistant general manager of the Niles Tool Works at Hamilton, Ohio. During the next three years, he traveled in different parts of the world. He established his own office as consulting engineer in New York in 1895, and engaged in that work until his retirement about 1912.

Mr. Hall invented the automatic control for the return system of steam heating now in practically universal use, and other engineering devices and methods. He was one of the early proponents of the electrification of steam railroads and submitted a paper on this subject before the A.S.M.E. in 1890. He was also one of the first to experiment with direct electric drive for machine tools. He was the author of "Car Lubrication" and of various other papers before the A.S.M.E. and other technical societies.

Mr. Hall became a member of the A.S.M.E. in 1889. He was a life member of the Historical Society of Pennsylvania and of the Red Cross. He also belonged to the China Society and to a number of technical and social clubs. He married Ina B. Fenner, of Hillsboro, Ohio, in 1890.

RUDOLPH L. HANAU

Rudolph L. Hanau, president of the Hanau Engineering Company, Buffalo, N.Y., died on November 1, 1930. He was born at Victoria West, Cape Colony, S.A., on November 3, 1881. He was graduated in 1905 from the Technical Institute at Darmstadt, Germany. Prior to that he had served an apprenticeship with the Fabrik für Brauerei Einrichtungen Gehrke, in Berlin. He also had some early experience as assistant director with Siemens & Halske, Frankfurt, Germany. Following the completion of his technical education, he secured a position as draftsman for the Machinfabrik Hyligenstaedt, Giessen, Germany.

Mr. Hanau came to the United States in 1906 and prior to his connection with the Hanau Engineering Company in 1907, at that time located in New York, he was engaged as draftsman and designer at the offices of the New York Central Railroad. The Hanau Engineering Company, manufacturers of dental instruments, transferred its headquarters from New York to Buffalo in 1918.

Mr. Hanau became a member of the A.S.M.E. in 1926. He had contributed numerous articles to the *American Machinist* and to dental journals. He made outstanding contributions to prosthetic dentistry by instrumentation as well as technique; fundamental are his "Laws of Articulation," "The Articulation Quint," and many other results of his researches which he presented to the dental profession in numerous and voluminous articles published in dental journals. His teachings are included in the curricula of many dental colleges in the United States and abroad.

Surviving Mr. Hanau is his widow, Isabella (Lus) Hanau, whom he married in 1929.

FREDERICK AUGUSTUS HANNAH

Frederick Augustus Hannah, who died of heart trouble on December 5, 1930, in New York, was a native of Massachusetts, having been born at Medford, on January 18, 1873. His parents were William Augustus and Amelia (Adams) Hannah. He attended public schools at Chelsea, Mass., and was graduated from the Massachusetts Institute of Technology with an S.B. degree in 1895. During the following year he was an assistant in the applied mechanics laboratory at M.I.T. He spent the summer of 1896 as fireman for the West End Street Ry. Co., now the Boston Elevated, and as draftsman with the B. F. Sturtevant Co., and inspector of foundation construction for Rand & Taylor and Kendall & Stevens in Boston. He returned to M.I.T. that fall as assistant in mechanical drawing. During the next summer he was employed as draftsman by Miller & Shaw, and by E. F. Woodbury, engineer and patent solicitor, Boston. He became an instructor in mechanical engineering at M.I.T. in

the fall of 1897, and held this position for two years. His vacation work during that period included the design of automatic machinery for the Electrical Machine Company, Boston.

During the winter of 1899–1900, Mr. Hannah was an instructor in mechanical engineering at the Polytechnic Institute of Brooklyn. He helped to equip new shops and the hydraulic laboratory, and taught shop work and machine drawing and design. During the next year he designed and superintended the construction of special machinery for the American Tobacco Company at its New York shops. From 1902 until his death he was engaged in consulting work, making New York his headquarters. He served the Crosby Steam Gage & Valve Co. as superintendent for a time and also was connected with the American Smelting & Refining Co., the American Radiator Company, the Wilson Welder & Metals Co., and the Boston & Worcester Street Ry. as general manager for its receiver. For a time he was an instructor in evening courses in industrial management at M.I.T. The year prior to his death was spent in Russia as industrial management engineer for the U.S.S.R.

Mr. Hannah became a junior member of the A.S.M.E. in 1900 and member in 1904. He belonged to the Sons of American Revolution and to the Engineers' Clubs in Boston and New York, as well as to several other clubs. He is survived by his widow, Anne Ruth (Judkins) Hannah, whom he married in 1927.

MERLE W. HATTON

Merle W. Hatton, whose death occurred on May 24, 1931, was born on November 6, 1888, at Alpena, S.D., the son of Richard and Cora (Thomas) Hatton. He received a B.S. degree in mechanical engineering from the Carnegie Institute of Technology, Pittsburgh, Pa., in 1913. During the next four years he was employed by the Mesta Machine Company, Pittsburgh, at first as assistant master mechanic and later as superintendent of electrical and mechanical maintenance. In 1918 and 1919 he served as mechanical expert in the Research Division of the Chemical Warfare Service, at the American University Experiment Station, Washington, D.C.

Since 1919 Mr. Hatton had been connected with the American Sheet and Tin Plate Company, for six years as master mechanic at the Gary Tin Mill, Gary, Ind., and since then as resident engineer at Canton, Ohio.

Mr. Hatton became an associate-member of the A.S.M.E. in 1918. He is survived by his widow, Mrs. Elizabeth Fiske Kennedy Hatton, whom he married in 1919.

ELMER LELAND HAYWARD

Elmer Leland Hayward, who died of heart trouble on May 2, 1930, in Chicago, Ill., was born on May 26, 1866, at Port Henry, N.Y. His parents were Eugene B. and Ellen E. (Phelps) Hayward. Mr. Hayward was educated in the public schools of Davenport, Iowa, and Pratt Institute, Brooklyn, N.Y., from which he was graduated as a mechanical engineer in 1901. His early experience was obtained with Robert Horton on the upper Mississippi River, with the Eagle Lumber Company at Eagle Mills, Ark., of which he was for a time vice-president, in power plant work, and at the Chicago World's Fair in 1892 and 1893, where he installed fire protection and sewerage systems. He was associated with the Kimball Engineering Company and Cable Lumber Company at Davenport, Iowa, and the Belding-Hayward Company at Chicago. He remodeled several water works plants and had charge of motive power and was president of the Freeo Valley Railroad Company and the Nacogdoches & Southeastern Railroad Co. Later he engaged in consulting work and also taught machine shop practice at Pratt Institute. At the time of his death he was vice-president of the North American Timber Holding Company, Chicago.

Mr. Hayward entered the A.S.M.E. as a junior in 1902 and became a member four years later. He was a member of the Chicago Yacht Club and was interested in making small working models of engines. He married Fannie May Pierce in 1886 and is survived by her and by one daughter, Lulu (Hayward) Calkins, of Los Angeles, Calif.

JAMES NICHOLS HEALD

James Nichols Heald, president and general manager of the Heald Machine Company, Worcester, Mass., died at his home in that city on May 7, 1931, of heart disease. He had been in poor health for several years and although he had not entirely given up active participation in the management of the company, he had relinquished many duties to his sons Roger, vice-president and works manager, and Richard, secretary and treasurer. He is survived by two other sons, Robert and Stanley, and by his widow, formerly Mabel Allen, of Barre, Mass., whom he married in 1894.

Mr. Heald was born in Barre on September 21, 1864, the son of Leander S. and Anna A. (Nichols) Heald. His early education was obtained in Barre and he was graduated in 1884 from the Worcester Polytechnic Institute with the degree of bachelor of science. At that time his grandfather, Stephen Heald, who had established the business in 1826, and his father, were associated in the machine shop and foundry work then known as S. Heald & Son. James became superintendent and designer and when his grandfather died in 1888, took over the management of the business, which was reorganized as L. S. Heald & Son. He saw the place which the grinding machine must have in the growing automobile industry and concentrated on this phase of the work of the company. Drill grinders, center grinders, and miscellaneous grinding attachments were products of those early years.

In 1903 James Heald bought out his father's interest, organized the Heald Machine Company, and, in order to secure better labor supply and transportation facilities, transferred the business to Worcester. He now began the development of a long line of internal grinding machines. The Heald ring and surface grinder was the first machine of the new line, designed for the automobile trade. Then he brought out cylinder grinders and internal grinders for mass production at low cost. A subordinate line was magnetic chucks for holding work. Not only the automobile industry, but also manufacturers of all internal combustion engines were greatly benefited by his achievements in the design and manufacture of grinding machines, and he built up in Worcester an industry employing, in busy times, some eight hundred men.

Mr. Heald was for many years a member of the National Machine Tool Builders' Association and served as its treasurer and for three years on its board of directors. He was made a member of the A.S.M.E. in 1917 and belonged also to the Society of Automotive Engineers. Locally he was a member of the Commonwealth, Country, and Rotary clubs, the Worcester Chamber of Commerce, and the Worcester County Mechanics Association. He was a director of the Worcester Bank & Trust Co. and a trustee of the People's Savings Bank. He attended the Plymouth Congregational Church and was a member of the Board of Assessors of Worcester.

WARREN M. HEALEY

Brigadier-General Warren M. Healey, a Civil War veteran and retired manufacturer of carriages and automobile bodies, died at the Neurological Institute of the Medical Center in New York, on March 25, 1931. He had been in ill health for several months. He had resided at the Union League Club in New York and at his country home at Cornwall-on-the-Hudson since his retirement from business in 1919.

General Healey was born in Norfolk County, Massachusetts, on August 3, 1840, the son of Samuel and Mary Thayer (Mansfield) Healey. He was educated as a mechanical engineer in technical schools in France. From 1865 to 1876 he was general manager for Wood Brothers, Bridgeport, Conn. He established his own business as a coach and carriage manufacturer in New York in 1880 under the name of Healey & Co. With the coming of the automobile he adapted his factory to the production of motor car bodies. He invented a machine for centering and boring hubs of wheels, and for the craftsmanship of his products he was made Chevalier of the Legion of Honor of France in 1889.

General Healey served through the Civil War and was a member of the Grand Army of the Republic. He was one of the original commission for the construction of the Grant Monument in New York and was a trustee of the Grant Monument Association. Following the war he became a member of the New York National Guard, attaining the rank of brigadier-general in 1897. He was vice-president of the Union Dime Bank in 1881 and 1882 and a director of the Hudson Trust Company from 1884 to 1919.

General Healey became a life member of the A.S.M.E. in 1925, and also belonged to the Sons of the American Revolution, the Mayflower Descendants, the New England Society, the New York Historical Society, the New York Chamber of Commerce, American Museum of Natural History, and a number of clubs, including the Metropolitan and Army and Navy.

CHARLES LOUIS HEISLER

Charles Louis Heisler, inventor of the Heisler geared locomotive, and many other items, died at his summer home at Rock City Falls, near Schenectady, N.Y., on October 13, 1931.

Mr. Heisler was born on February 22, 1863, at Wapakoneta, Ohio, the son of Christian and Christina (Lang) Heisler. He was educated in the public schools of that town and at the Cascadilla Preparatory School at Ithaca, N.Y. He was graduated from Cornell University

in 1890 with the degree of mechanical engineer. He was a member of the honorary society of Sigma Xi.

Mr. Heisler had special training in carriage smithing, machine work, and patternmaking as a boy in several shops at Wapakoneta, Ohio, and at St. Marys, Ohio. He withdrew from college for a year to work for the Brooks Locomotive Works, at Dunkirk, N.Y., as engineer of tests in charge of the training school for apprentices. After completing his college education, he returned to this company for two years, performing development work for the president of the company.

During this period, the geared locomotive was developed by Mr. Heisler. His conception of the simple locomotive gear drive with bevel wheel and pinion is said to have anticipated the live-axle and cardan shaft principle of the modern motor car. The Baldwin Locomotive Works took over the manufacture of the locomotive until a manufacturing company was capitalized by business men of Erie, Pa., to whom Mr. Heisler disposed of his interests in the invention.

After the death of the president of the Dunkirk Engineering Company, Mr. Heisler accepted a position with Bement, Miles & Co. working on large machine tools in the engineering department. He developed a high-duty reciprocating pumping engine which was manufactured in a plant at St. Marys, Ohio, known as the Heisler Pumping Engine Company. Mr. Heisler operated this plant for some years, as vice-president and chief engineer, until in 1907 the plant was discontinued.

Mr. Heisler then became connected with the American Locomotive Works, into which the Brooks Locomotive Works and other companies had been merged, as a member of its staff of mechanical engineers. While with that company he developed and invented many improvements in locomotive and machine tools.

At the beginning of the World War, Mr. Heisler was located at Providence, R.I., in the plant of the Alco Manufacturing Company, which was controlled by the American Locomotive Company. He developed devices for manufacturing shells and other ammunition, and after a time became associated with the Washington Steel and Ordnance plant, manufacturers of large armor-piercing and high-explosive shells.

His career with the General Electric Company began in 1922. From that year until 1926 he was in charge of the mechanical engineering department of the general superintendent's office. He engaged in the development of sound recorders and combined sound-reproducing and moving-picture projecting machines in the photophone department, mechanical engineering section. At the time of his death he was in the general engineering department, engaged in the development of refrigerating machines and reversible airplane propeller mechanisms. Other results of his ingenuity were pointed out in a statement at the time of his death by Charles E. Eveleth, vice-president in charge of designing, who said, in part, "While with the General Electric Company he made valuable contributions to the design of geared turbines, hundreds of jigs and fixtures to assist in manufacture; he designed wire enameling machines, paper and asbestos covering machines for wire, as well as dozens of improvements in the design of standard apparatus contributed from the manufacturing standpoint to improve quality and reduce costs." Since joining the staff of the General Electric Company he had been granted 21 patents.

His principal inventions were the Heisler geared locomotive engine, various types of pumping engines and machinery, steam road rollers, water-works pumping machinery, barometric condensers, wet type vacuum pumps, combined sound reproducing and moving-picture projecting machines, refrigerating machinery, and various other types of machinery.

Mr. Heisler became a member of the A.S.M.E. in 1895. He also belonged to the American Association for the Advancement of Science and was a 32nd degree Mason.

He is survived by his widow, Mrs. Laura (Barton) Heisler, of Dunkirk, N. Y., whom he married in 1891, by three sons and a daughter, and by one brother.

WILLIAM FERRIS HENDRY

William Ferris Hendry died at Ossining, N.Y., on January 8, 1930. He was born at Wellsboro, Pa., on August 17, 1873, the son of William Montgomery and Henrietta (Ferris) Hendry. His education included three years at Betts Academy, Stamford, Conn., two years at Cornell University in special engineering work, a student course with the General Electric Works, and an apprenticeship with the Baldwin Locomotive Works and Edison Electric Company. He engaged in general construction work and had charge of the power plant at the New York Navy Yard from 1895 to 1898. The following year he was connected with the Sprague Electric Company as an erecting engineer. He then entered the employ of the Western Electric Company as assistant to the factory engineer and remained with this company for some years, serving successively as factory engineer, assistant superintendent, and superintendent, in New York, and then as technical superintendent at the Hawthorne Works, Chicago. At the time of his death he was vice-president and chief engineer of the Manhattan Electrical Supply Company, New York, and also vice-president of the Troy Laundry Machinery Company, Trout Mining Company, and the United States Manganese Company.

Mr. Hendry designed and patented several motor controlling devices for machine tools and automatic-return sand-blast machines, automatic valves, radio tubes, dry-cell batteries, and automatic package machinery. He became a member of the A.S.M.E. in 1907 and also belonged to the American Institute of Electrical Engineers and the American Chemical Society. He was interested in archeology as well as in engineering. He is survived by his widow, Bess (Sheldon) Hendry.

LOUIS GEORGE HENES

Louis George Henes, who died on November 1, 1931, in New York, N.Y., was born in that city on May 25, 1881, the son of Edwin and Caroline (Schiffer) Henes. He secured his preparatory education at the German-American School there and at the City College of New York. He was graduated from Columbia University with an M.E. degree in 1903. His early experience in engineering was secured during his vacations with the A. J. Lindeman & Hoverson Co. in Milwaukee, in the toolroom of the De LaVergne Refrigerating Machine Company, New York, and in the mechanical laboratory at Columbia University. He served an apprenticeship with the Niles-Bement-Pond Company and from 1904 to 1906 was assistant to the manager of the New York Office of the company. He then became manager of the Machinery Department of Harron Rickard & McCone in San Francisco.

Mr. Henes went into business for himself in San Francisco and Los Angeles in 1909 under the name of the L. G. Henes Machinery Company, which was reorganized and incorporated in Los Angeles in 1931 as the Henes-Morgan Machinery Company, Ltd. He was also Pacific Coast manager for Manning, Maxwell & Moore, Inc., and the Commercial Acetylene Company, both of New York, and for the Railway Materials Company of Chicago.

Mr. Henes joined the A.S.M.E. as a junior member in 1903 and became an associate of the Society in 1910.

Surviving Mr. Henes are a son and daughter. He married Evelyn Ellis, of Oakland, Calif., in 1914.

HILARY J. HENNESSY

Hilary J. Hennessy, chief mechanical draftsman for the Northern Pacific Railway Company, St. Paul, Minn., died suddenly of heart trouble on July 12, 1931. Mr. Hennessy became a member of the A.S.M.E. in 1929. He was born at Chicago, Ill., on October 25, 1889. His technical education was secured through the International Correspondence Schools and the Armour and Lewis Institutes of Chicago. From 1907 to 1911, he engaged in drafting for the National Dump Car Company and the Rodger Ballast Car Company in Chicago. During the next two years, he installed and operated laundry power plant machinery for the Lutz Laundry Machine Company and Sheridan Park Laundry of that city. He had been with the Northern Pacific Railway Company since 1913. His father, J. H. Hennessy, of Chicago, and a daughter, Lorraine Jean Hennessy, survive him. Mr. Hennessy belonged to the Masonic fraternity.

GEORGE HILLYER, JR.

George Hillyer, Jr., whose death occurred in Washington, D.C., on April 24, 1931, was born in Atlanta, Ga., on November 6, 1872, the son of Judge George Hillyer and Ellen E. (Cooley) Hillyer. He received an A.B. degree from the University of Georgia, Athens, Ga., in 1893, and an M.E. from Cornell in 1896.

For a year following the completion of his college work Mr. Hillyer was employed by the Atlanta Talc & Soapstone Mining & Manufacturing Co., Murphy, N.C., as mechanical engineer. He then served a two-year special apprenticeship in the drawing room and shops of the Southern Railway at Atlanta, and worked as draftsman for that road at Washington for several years.

In 1901 Mr. Hillyer went to Detroit as draftsman for the American Car & Foundry Co. The following year he secured a position on the operating board of the American Radiator Company in Chicago. Later he was promoted to the engineering department of the company, and in 1905 became its resident salesman in Atlanta. From 1907 to 1910 he was manager of the Atlanta office of the American

Radiator Company. During the next five years he engaged in consulting engineering in Atlanta.

Since 1916 Mr. Hillyer had been with the Southern Railway, for several years as mechanical engineer in its valuation department in Atlanta, and during the remainder of his life as mechanical engineer of the Southern Railway System, with headquarters at Washington, D.C.

Mr. Hillyer joined the A.S.M.E. as a junior member in 1898, and in 1904 became an Associate of the Society. He was a member and former trustee of the Cornell Alumni Association, a member of the Sons of the American Revolution, the Founders and Patriots of America, National Geographic Society, the Virginia and Georgia Historical Societies, the Chi Phi fraternity, and the American Association for the Advancement of Science, as well as several clubs. He was a Thirty-Second Degree Mason, a Knight Templar, and a Shriner. He had been a member of the Second Baptist Church in Atlanta for 44 years.

Mr. Hillyer is survived by his widow, Mrs. Edith (Carter) Hillyer.

HERMAN EDMUND HOFFSTADT

Herman Edmund Hoffstadt, until recently mechanical engineer for the Mayflower Hotel, Washington, D.C., died on February 18, 1931, at his home in New York, N.Y. He is survived by his widow, Marie A. (Spengler) Hoffstadt, whom he married in 1925, and by one son, Herman Edmund Hoffstadt, Jr.

Mr. Hoffstadt was born on October 2, 1884, in New York, and after completing his high-school education served an apprenticeship in the Kingsbridge and Interborough power plants of the New York Central Railroad as an oiler and dynamo tender. He was then engaged in construction work and the installation of ice machines and gas and oil engines for the De La Vergne Machine Company.

In 1905 Mr. Hoffstadt began work as an oiler at the Municipal Ferry, New York. He obtained a marine license four years later and in 1911 his stationary engineer's license. He served the city until 1917 when he enlisted in the U. S. Navy as a warrant machinist for the reconstruction of vessels for sea duty. Following his release from the Navy after the close of the War he entered Teachers College, Columbia University, under Government tuition to study mechanical drawing, machine design, etc. He completed his course in 1923 and during the next two years served as safety engineer and inspector on steam engines and boilers throughout the United States.

Since 1925 Mr. Hoffstadt had been employed by private concerns. For about six months he was chief engineer and building superintendent for the Sam & Lee Shubert Theater Corporation, in charge of the Broadhurst and Plymouth theaters in New York. He then became assistant superintendent of highways and construction for the John H. Sullivan Construction Company, laying water mains and building conduits and roads. Prior to his connection with the Mayflower he was superintendent and chief engineer of the Wall Street Exchange Building, New York.

Mr. Hoffstadt became an associate member of the A.S.M.E. in 1923 and was promoted to full membership in 1927.

LEO HOLDREDGE

Leo Holdredge, who died suddenly at Knoxville, Tenn., on April 12, 1931, was born at Kent, near Akron, Ohio, on July 2, 1886, the son of S. T. and Ida May (Barrick) Holdredge. In his early youth his parents moved to Louden County, Tennessee, where he attended the public schools. He continued his studies at Tennessee Wesleyan College, formerly known as Grant University, at Athens, and then served for a number of years as principal of a Methodist Seminary at Epworth, Ga. This period was followed by a business affiliation at Lenoir City, where he was senior member of the firm of Holdredge and Kollock, hardware dealers.

In 1921, Mr. Holdredge decided to continue his education and entered the Engineering College of the University of Tennessee. During his junior year he was selected as the outstanding engineering student and was awarded the scholarship prize offered by that institution. He was graduated with a B.S. degree in mechanical engineering in 1926 and two years later received his M.E. degree.

During the summer of 1926 he engaged in time study and efficiency tests for The Fulton Company, at Knoxville, Tenn. He returned to the University as instructor in mechanical engineering in September, and in 1930 was advanced to the rank of assistant professor of mechanical engineering. During this period he was the author and co-author of a number of Engineering Experiment Station research bulletins, especially on subjects pertaining to fuel and heating and ventilation, and was at the time of his death assisting in preparing a text on heating and ventilation.

Professor Holdredge became an associate member of the A.S.M.E. in 1926 and was serving the Knoxville Section as secretary at the time of his death. He had just completed a technical research paper in cooperation with Prof. E. L. Carpenter at the University of Tennessee on the "Cotton Oil Industry of the South" for presentation at the Semi-Annual Meeting of the Society at Birmingham, Ala. He was also a member of Phi Kappa Phi and Tau Beta Pi, honorary fraternities, and of the Knoxville Technical Society.

He joined the Methodist Episcopal Church at a very early age and was active throughout his life in the major activities of this denomination, and particularly in the Epworth League and other work with young people.

He married Miss Leta Cardwell of Lenoir City, Tenn., in 1914, and is survived by her and by three sons and one daughter.

EDGAR MALIN HOOPES, JR.

Edgar Malin Hoopes, Jr., member of the staff of the Governor of Delaware, and engineer for the E. I. du Pont de Nemours Co., at Wilmington, Del., died on November 20, 1931. Colonel Hoopes was born on May 18, 1888, at Wilmington, Del., the son of Edgar Malin and Elizabeth (Osborne) Hoopes. He received a Ph.B. degree from the Sheffield Scientific School of Yale University in 1910. He had had some experience during summer vacations in testing materials and in surveying for water supply and sewage systems in Charleston and Romney, W. Va., and in Wilmington. Following his graduation, he was employed by Joseph Bancroft & Sons Co., at Wilmington and Reading, Pa., on the design of power plant additions, special bleaching and dyeing machinery, and as engineer on steam economy tests. In 1911, he became connected with the Board of Water Commissioners of Wilmington. He worked on the design of proposed water-power developments and hydraulic-turbine installations. He was appointed assistant engineer before the end of that year, and in 1915 chief engineer in charge of operation and construction work for the water department, engineering and survey department, and street and sewer department of the City of Wilmington.

In 1918, Mr. Hoopes received a Captain's commission and served at Camp Meade and Fortress Monroe. After the war, he became a member of the engineering staff of the duPont Company and later was engineer for the Elafrael Corporation, composed of the family of Senator du Pont. He was commissioned a colonel on the staff of Governor Buck in 1929. He also served on the Board of Water Commissioners from 1921 until his death, and was a director of the Wilmington Savings Fund, the Wilmington Library, the Fine Arts Society, and the Regional Planning Commission.

Mr. Hoopes became an associate member of the A.S.M.E. in 1917. He married Helen Nelson Bain, at Newburgh, N.Y., in 1913.

CHARLES HENRY HORN

Charles Henry Horn, of Howard Beach, Long Island, N.Y., died on July 25, 1931. Mr. Horn was born at Astoria, Long Island, on March 25, 1882, the son of David and Anna (Beck) Horn. His first position was as toolroom foreman with the John Thomson Press Company in Long Island City, for whom he later became assistant superintendent of tools. After three years with this company, he took a similar position with the Automatic Products Corporation in Long Island City. From 1922 until 1927, when the Tool Room and Production Departments were in his charge, he worked directly with Mr. John Thomson on the perfection of the Thomson Adriance Meter, and also did experimental work on a new feeder. Subsequently, he turned his attention to the design and supervision of the manufacture of drill jigs, dies, etc.

Mr. Horn became an associate member of the A.S.M.E. in 1930, and also belonged to the Masonic fraternity. He is survived by his widow, Minnie (Naumann) Horn, whom he married in 1914, and by three children, Charles W., Howard H., and Anita D. Horn.

THOMAS ROGERS HUGHES

Thomas Rogers Hughes, who died at St. Joseph, Mo., on August 2, 1931, was born at Oxford, Ohio, in 1902. He received an A.B. degree from the Miami University in 1924 and a B.S. degree from the Massachusetts Institute of Technology two years later. He then entered the employ of the American Waterworks & Electric Co., in New York. His duties included the selection and layout of mechanical equipment of waterworks and pumping stations. He was connected with this company at the time of his death.

Mr. Hughes became a junior member of the A.S.M.E. in 1929 and also belonged to the American Society of Civil Engineers.

JOHN W. HUNNS

John W. Hunns, assistant at the Physical Laboratory of The Russell Manufacturing Company, Middletown, Conn., died on February 25, 1931. Mr. Hunns became a junior member of the A.S.M.E. in 1930, and was a member of the Third Congregational Church in Middletown.

The son of George and Mary M. (Williams) Hunns, he was born on June 7, 1907, at Middletown and attended the high school there. In 1926 and 1927 he worked as an inspector on clutch facings and brake linings for the Russell company, and during his vacations while attending Pratt Institute he was also employed by the company, part of the time on inspection and part on production work. He returned to Middletown as assistant at the Physical Laboratory following the completion of his course at Pratt in June, 1930.

Mr. Hunns is survived by his father and mother and by a brother.

HARRY BURLEIGH HUNT

Harry Burleigh Hunt was born in New York, N.Y., on March 8, 1875, the son of James Baldwin and Estelle M. (Hinckley) Hunt. His early education was obtained in the schools of Brooklyn and he was graduated as a mechanical engineer from the Massachusetts Institute of Technology in 1897. He entered the employ of the Erie Railroad at Susquehanna as a special apprentice and remained with that road as draftsman, engineer of tests, and assistant mechanical superintendent for eight years. He resigned in 1905 to accept a position with the American Locomotive Company. During the twelve years he was associated with this company he was a member of its Engineering Committee. He was manager of the Electric Locomotive Department in 1906 and 1907, and for the next two years was employed jointly by the American Locomotive Company and the General Electric Company to investigate the electrification of steam railroads. He was made assistant to the president, Mr. Waldo H. Marshall, in 1914, and placed in charge of sales and the production of artillery ammunition; he was appointed vice-president in February, 1917. He placed the manufacture of munitions on a workmanlike and profitable basis.

In June, 1917, Mr. Hunt was granted leave of absence and entered the U. S. Army as a Major in the Ordnance Reserve Corps. He was assigned to the Gun Division in charge of production of cannon, where his technical knowledge, coupled with his administrative ability and understanding of sound finance, were of inestimable value to the Government. He was promoted to the rank of Lieutenant-Colonel in January, 1918, and in November of that year to Colonel in the Ordnance Department, assigned to the Artillery Ammunition Division. He was discharged from service in January, 1919.

During 1920 he was associated with George W. Goethals & Co., Inc., as vice-president and general manager of the Automatic Straight Air-Brake Company. Ill health caused by intensive work during the war necessitated his resignation at the end of 1920, and since that time he had not been active in business, although he had made some studies of manufacturing for industrial companies.

Mr. Hunt became a member of the A.S.M.E. in 1916 and also belonged to the New York Railroad Club, the Engineers' Club of New York, and the University Club of Chicago. He died in New Rochelle, N.Y., on July 25, 1929, of heart failure. His estate was left in trust for a surviving sister and a friend, with the provision that eventually it should go to the Massachusetts Institute of Technology.

WILLIAM SPENCER HUNTINGTON

William Spencer Huntington was born at Fairbanks, Iowa, on June 23, 1867, the son of William and Maria (Spencer) Huntington. His early edu ation was obtained at Oran and at Oelwein, and he taught in that vicinity before taking up the study of engineering. He was given a B.S. degree in civil engineering by the University of Iowa in 1895. His first position was at Oelwein, where he engaged in water-works construction during the year following his graduation, and was the first superintendent of the works. The next year was spent as draftsman on steel bridges for the Bellefontaine Bridge & Iron Co., Bellefontaine, Ohio. He did similar work for the American Bridge Company, Minneapolis, Minn., from 1897 to 1900. The next eight years were spent with the St. Paul Foundry Co., St. Paul, Minn., first as chief draftsman and then as chief engineer. His duties included the design of structural steel work and the rebuilding of the company's plant.

In 1908 Mr. Huntington went to Kansas City, Mo., to accept the position of chief engineer for the Kansas City Structural Steel Company. He resigned this position in 1913 to engage in general engineering work at Galveston, Texas. From 1915 until his retirement in 1928 he was identified with the C. L. Brooks Engineering Co. and The Moultrie Construction Company of Moultrie, Ga., for which he designed packing houses and cold storage plants in this country and in Cuba. During the World War he was engaged in work on explosives for the United States Government in New York and at Nitro, W.Va.

He had traveled extensively through the United States since his retirement, and was on the way from Oelwein to Florida when his death occurred, at Streator, Ill., on December 5, 1931.

Mr. Huntington became an associate member of the A.S.M.E. in 1917. He had written books on refrigeration and contributed articles on that subject to the technical press. He is survived by his widow, Sarah M. A. (Smith) Huntington, whom he married in 1899.

OREN S. HUSSEY

Oren S. Hussey, retired, resident of Nashua, N.H., died at Bradenton, Fla., on February 8, 1931. Mr. Hussey was born in Nashua on May 16, 1865, and attended the public schools there. He then entered the Massachusetts Institute of Technology, from which he was graduated in 1887 with an S.B. degree. Following his graduation Mr. Hussey worked at the laboratory of Thomas A. Edison in Orange, N.J., engaged primarily in experimental work, until 1890. During this engagement, he designed an air separating plant which was erected at Humboldt, Mich., and a similar installation at Bechtelsville, Pa. From 1890 to 1892 he was mechanical engineer for the Thomson, Houston Motor Company, Boston, Mass., having charge of all engineering work of the company, installation of power plants, etc. He then engaged in business for himself in Boston for two years, in the firm of Bailey & Hussey, wholesale building supply company. In 1894 he became a member of the firm of Gregg & Son, door and sash manufacturers, of Nashua. He retired from this firm in 1904 to become treasurer of the Frank Ridlon Company, Boston, a position he held until 1915, when he retired because of ill health.

During the World War Mr. Hussey held a civilian post in the Ordnance Division of the War Department at Washington, D.C.

Mr. Hussey became a member of the A.S.M.E. in 1897. He is survived by his widow, Mrs. Margie L. Hussey, whom he married in 1889.

FRANKLIN KILSHAW IRWIN

Franklin Kilshaw Irwin died on April 6, 1931, at Ardmore, Pa., where he had resided since his retirement from active business in 1929. Mr. Irwin was the son of Thomas Kilshaw and Mary (Ketchum) Irwin. He was born at Mobile, Ala., on December 4, 1859. He attended Towle's Collegiate Institute there and was graduated from the Stevens Institute of Technology as a mechanical engineer in 1883. His first position was as draftsman with the American Ship Building Company in Philadelphia. From 1884 to 1900 he was connected as machinist apprentice, draftsman, and mechanical engineer with the Wisconsin Central Railroad and continued his studies through the International Correspondence Schools. During the next three years he was assistant engineer in charge of design and construction of repair shops and equipment for the Union Pacific Railroad, Omaha, Neb. After a short time in 1903 with the Galena Signal Oil Company of Franklin, Pa., he accepted a position as engineer of construction with the New York, New Haven & Hartford R.R., being appointed superintendent of bridges and buildings for that road in 1908. From 1911 to 1914 he was special engineer and superintendent of the Boston and Maine Railroad.

Mr. Irwin took up sales work in 1915 as agent for the Babcock & Wilcox Co. of Boston. He was transferred to the Chicago sales force the following year and in 1917 became sales manager of the Philadelphia Niles-Bement-Pond Company. From 1924 until 1929 he was sales engineer for the Combustion Engineering Corporation of Philadelphia.

Mr. Irwin became a member of the A.S.M.E. in 1913. He belonged to the Pennsylvania Historical Society, the Manufacturer's Club of Philadelphia, and the Masonic fraternity. Surviving him is his widow, Mary (McHenry) Irwin of Haverford, Pa., whom he married in 1890, and one son, Kilshaw McHenry Irwin.

CARL ALBERT JOHNSON

Carl Albert Johnson, president of the Gisholt Machine Company, Madison, Wis., died on October 30, 1931. Mr. Johnson was born at Madison on April 21, 1870, the son of John A. and Kaia (Kildahl) Johnson. He received a degree in mechanical engineering from the University of Wisconsin in 1891. During his vacations he had worked in the machine shop and drafting room of the Gisholt Machine Company, and following his graduation he continued in the business of this company. He devoted a great deal of his time to the tools and

appliances used with their machines and traveled both in the United States and in Europe in the interests of the company. He was appointed general manager in 1895 and president in 1908.

Mr. Johnson became a member of the A.S.M.E. in 1901. He had served as president of the Wisconsin Manufacturers' Association for seven years and was a past-president of the National Machine Tool Builders' Association. He was a director of the U.S. Chamber of Commerce, founder and first president of the Madison Association of Commerce, and a director of the First National Bank in Chicago and of the Cutler-Hammer Manufacturing Company of Milwaukee.

Surviving Mr. Johnson are his widow, Mrs. Lucy (McGlachin Berry) Johnson, whom he married in 1927, and Mrs. Ruth (Johnson) Weston, a daughter by a former marriage.

JOHN SAMUEL ADOLPHUS JOHNSON

John Samuel Adolphus Johnson was born at Cismont, Va., on August 10, 1878, the son of Wm. Whitfield and Katherine M. (Anderson) Johnson. He attended public and private schools in that vicinity and was given a B.S. degree in mechanical engineering by the Virginia Polytechnic Institute, Blacksburg, Va., in 1898, and an M.E. degree the following year. He also studied at Cornell University in the summer of 1902 and at Lehigh University in the summer of 1908. Another summer was spent at the Baldwin Locomotive Works to secure practical experience. The remainder of his life was spent in teaching at the Virginia Polytechnic Institute. He was made assistant professor of mechanical engineering in 1900, after having been an instructor in that subject and in military science and tactics since his graduation. In 1906 he was given the chair of experimental engineering. Since 1914, he had been professor of applied mechanics and experimental engineering, and since 1921 had been director of the Virginia Engineering Experimenting Station.

Professor Johnson became a member of the A.S.M.E. in 1911. He also belonged to the American Society for Testing Materials, and the Society for the Promotion of Engineering Education. He had contributed a number of articles to the technical press.

Surviving Professor Johnson are his widow, Margaret M. A. (Smyth) Johnson, whom he married in 1905, three daughters, and a son. Professor Johnson, who had been in ill health and had been advised to give up his work for a time, committed suicide on October 21, 1931.

JOSEPH EDWARD JOHNSON

Joseph Edward Johnson died of heart failure on May 16, 1930, at his home in Meriden, Conn. He was a native of Sweden, having been born at Elssborg on September 22, 1865, the son of Johan Persson and Bendikta (Carlson) Johnson. He attended the public schools of Elssborg, served an apprenticeship at the Halmstead's Mechanical Works, and gained experience as a toolmaker at plants of other Swedish firms. He came to the United States in 1889 and worked at his trade with different firms here, among which was the New Haven Clock Company, for which he designed special subpress dies for blanking finished clock wheels and other parts from sheet metal in one operation. From 1897 to 1905 he was connected with The M. B. Schenck Co., now the Bassick Company, of Meriden, Conn., designing all machine tools and automatic machines used in the manufacture of furniture and truck casters. He was in charge of the tool and machine department of the company and redesigned and improved the Schenck hydraulic water-wheel governors, manufacturing, selling, and installing them in some of the largest power plants in the eastern part of the country. In 1905 Mr. Johnson went to Rochester, N.Y., as factory superintendent for the Pritchard-Strong Mfg. Co., manufacturers of lanterns and household utensils. He installed new automatic stokers and high-speed steam engines, as well as a complete lighting and heating system. He returned to the M. B. Schenck Co. in 1907 and remained with them for two years in work similar to that which he had previously done for the company. He then entered the employ of the Connecticut Telephone & Electric Co. of Meriden, as superintendent of the mechanical department, as well as of the different buildings of the company. When its molded insulation department was taken over by the Monowatt Company, he entered the employ of that firm as chief engineer.

Mr. Johnson had taken an active interest in civic affairs in Meriden, having been connected with the city government for more than twelve years. He was police commissioner under the former Mayor Daniel J. Donovan, and had served as alderman and mayor pro tem. He was chairman of the aviation commission of Meriden. He was a member and former president of the John Ericsson Republican Club of that city and treasurer of the state league of John Ericsson Republican Clubs.

Mr. Johnson became a member of the A.S.M.E. in 1916. He also belonged to the Odd Fellows and to several other fraternal societies. In 1898 he married Anna Louise Nelson, who, together with three daughters, survive him. Mr. Johnson held patents on a take-up device for crank-pin connections, speed regulator for hydraulic water-wheel governors, casters, and coffee percolators.

LEWIS ERNEST KEIL

Lewis Ernest Keil died on February 26, 1931, at the Walter Reed Hospital, Washington, D.C., where he had been confined since the middle of October, 1930. He was buried with full military honors in the Arlington National Cemetery. Mr. Keil served in the Ordnance Department from 1917 to 1919, being stationed at Camp Funston, Kansas, and using the shops of the Kansas State Agricultural College for the manufacture of precision clinometers of his own design for use in laying machine guns for the 89th Division.

Mr. Keil was born at Chicago, Ill., on May 15, 1887, the son of Louis E. Keil and Lorena C. Keil. His technical training was secured at the Chicago Manual Training School, which he attended for three years, and as a special apprentice in the locomotive shops of the Chicago Division of the Illinois Central Railway from 1904 to 1906. He received an E.E. degree from George Washington University in 1929 and an M.E. degree the following year.

During 1907 Mr. Keil was a draftsman and templetmaker for the Pullman Car Company, at Chicago, and from 1907 to 1908, draftsman and estimator for the Hicks Locomotive Company, Chicago Heights. As draftsman for four years with the Northern Pacific Railway Company at St. Paul, Minn., Mr. Keil worked on shop layouts and electrical wiring diagrams, as well as locomotive parts, cars, and trucks. In 1913 he gained experience in the design of refrigerator cars and trucks for the Moore Patent Refrigerator Car Company, St. Paul, building and equipping cars and testing them for a number of roads.

The following year he went to St. Louis, Mo., as chief draftsman for the St. Louis Car Company, in 1915 was appointed chief engineer, and the next year took on the additional duties of superintendent of the automobile shops. He was with this company until he entered the Army in 1917. Under his supervision some three hundred electric cars and trucks were built for the New York Railway Company, and as many more for the Manhattan and Queens Electric Railway, the Kansas City Railway Company, and the Pittsburgh Railway Company. He also directed the construction of a fleet of 150 all-steel motor buses for the Chicago Motorbus Corporation, and a variety of high-speed electric interurban equipment and trucks, including an express train equipment for the Grand Rapids, Kalamazoo High Tension Line of the Michigan Railway Company designed to operate on 600–1200 and 2400 volts d.c. As superintendent of the automobile shops he had charge of the machining of shrapnel cases for holding the fuse, bullets, and explosive, and designed the tools and jigs used for this work.

After the close of the War Mr. Keil became chief draftsman for the Texas & Pacific R.R. at Marshall, Texas, where he remained until May, 1920. During the remainder of that year he was connected with the Havana Central Railroad in Cuba. From then until 1925 he was mechanical engineer in the Bureau of Locomotive Inspection of the Interstate Commerce Commission at Washington, D.C. From 1925 to April, 1927, he was engaged as mechanical engineer by the Railway Locomotor Company, Chicago, and since July 1, 1927, had been assistant mechanical engineer at the Bureau of Yards and Docks of the U.S. Navy Department, Washington, D.C.

Mr. Keil was the patentor of electric motor car truck brakes used by the Pittsburgh and other electric railway companies and of a special design of electric railway trucks used under small electric railway cars built to meet bus competition. The St. Louis Car Company acquired rights to both these patents.

Mr. Keil had been an associate member of the A.S.M.E. since 1919.

Surviving him are his widow, Venita (Worley) Keil, his father, and one son, Lawrence E. Keil, of Chicago, Ill.

FRANK BOCKIUS KING

Frank Bockius King, retired naval architect and marine engineer, died at his home in Washington, D.C., on January 26, 1931, after an illness of three months.

Mr. King was born in Germantown, Philadelphia, Pa., on March 28, 1855, the son of Charles M. and Anna Louisa King. He attended the public schools of Philadelphia, and was graduated from the old Polytechnic College of Pennsylvania there with an M.E. degree in 1875. After some early training in the machine shop of John Roach & Sons, Philadelphia, he entered the marine field as an employee of Wm. Cramp & Sons, of that city. Another early contact was with the Pusey & Jones Co., in Wilmington, Del. In 1884 he was ship

draftsman at the Navy Yard at Washington and subsequently was associated with the chief constructor of the Bureau of Construction and Repair of the United States Navy in a study of European naval construction.

In December, 1886, Mr. King became superintendent of the Columbian Iron Works at Baltimore, Md., when the contract was secured for the construction of the gunboat *Petrel* for the U.S. Navy.

Mr. King was appointed marine superintendent of the Maryland Steel Company at Sparrows Point, Md., early in 1890, and a number of harbor and sea-going vessels were constructed under his supervision during the next four years.

In 1895 Mr. King opened an office in Baltimore for the practice of consulting marine engineering and naval architecture. He relocated in Washington the following year, and maintained his office there until his retirement.

Mr. King was twice married. In 1893 he married Helen Waldie Clark, of Philadelphia, who died in 1916. In 1918 he married Laura Larzelere Hofmann, also of Philadelphia, by whom he is survived. He was a member of the Society of Naval Architects and Marine Engineers, the American Society of Naval Architects, the Institution of Naval Architects, and the Washington Society of Engineers. He became a member of the A.S.M.E. in 1892.

HERMAN ARNOLD KIRBERG

Herman Arnold Kirberg, works manager of the Hanson-Van Winkle-Manning Company, Newark, N.J., died on November 25, 1931. Mr. Kirberg was born in New York, N.Y., on August 7, 1884, the son of Louise Veron and Herman Kirberg. After two years at Columbia University he entered the employ of the Western Electric Company, New York, where he was engaged for three years in making estimates and cost analyses. During the next four years he was employed by the Manhattan Electrical Supply Company at its Jersey City plant. He conducted research work on stock control and improved manufacturing methods. For a time he was in charge of the purchasing department and later general assistant to the works manager. From 1912 to 1917 Mr. Kirberg was connected with the Westinghouse Electric & Manufacturing Co. His duties included time studies, rate setting, and the improvement of manufacturing methods. For four years (1917–1921) Mr. Kirberg was assistant to the works manager of the Edison Phone Works in West Orange, N.J. He was production engineer on the Bates numbering machine and assisted in improving the existing designs and developing new ones. Since 1922 Mr. Kirberg had engaged in industrial engineering, largely in Newark and vicinity. For a time he was connected with Roth Brothers of Chicago, going from there to Newark to become works manager for its associated organization, the Hanson-Van Winkle-Manning Company.

Mr. Kirberg became an associate member of the A.S.M.E. in 1921. He is survived by his widow, Sadie E. (Welsh) Kirberg, whom he married in 1907.

LOUIS W. KLEIN

Louis W. Klein, whose death occurred at his home in Chicago on October 7, 1931, was a native of New York, N.Y., where he was born on April 2, 1874. He spent two years at the City College of New York, and four years with Hoe & Co., where he served an apprenticeship as a machinist, and studied in its mechanical and technical school. He remained with this company until 1913, serving successively as journeyman machinist, assistant foreman of manufacturing, and production engineer. During the next two years, he was foreman, first of the Ericsson Manufacturing Company, in Buffalo, N.Y., and later for the Packard Auto Company, Detroit. From 1916 to 1925 he was connected with the Coxe Traveling Grate Company, Port Carbon, Pa., as works manager. In this capacity, he designed many special tools, fixtures, and additions to the plant. Since 1925 he had been vice-president in charge of plant operation of the Green Engineering Company, East Chicago, Ind. He was also a vice-president of the Combustion Engineering Corporation, of which the Green Engineering Company is a subsidiary.

Mr. Klein became an associate member of the A.S.M.E. in 1921. He is survived by his widow, Lillie (Sommer) Klein, and by a son and two daughters.

EDWARD KNOWLES KNOWLTON

Edward Knowles Knowlton, power superintendent of the Bayonne Works of the Standard Oil Company, died of heart trouble at his home in Bayonne on May 14, 1930. Surviving him are two children, a son and a daughter.

Mr. Knowlton was born in Albany, N.Y., on October 16, 1871. He attended the Peekskill Military Academy and served an apprenticeship as a machinist with the Schenectady Locomotive Works in 1889 and 1890. During the next two years he was an apprentice, assisting in testing street railway motors, with the Edison Machine Company, now the General Electric Company, Schenectady. From 1892 to 1895 he was connected with the Fonda, Johnstown & Gloversville R.R., equipping interurban cars and instructing operators of them. He also operated engines and generators in the power house. For a time in 1895 he was employed by the Herkimer, Mohawk & Ilion Electric R.R. at Mohawk, N.Y., as assistant engineer of construction of electric power plants and equipping cars. The following year he went to Troy to design and superintend the installation of steam power plants for the Hammett Machine Company. After two years with this firm he went to Miami, Florida, where he had charge of the power plant for the Royal Palm Hotel during its reconstruction, and subsequently served as its chief engineer and had charge of all mechanical and electrical apparatus for the hotel. He also installed a gasoline electric plant for lighting in Miami and erected transmission lines there.

From 1900 to 1911 Mr. Knowlton was connected with Westinghouse, Church, Kerr & Co. and the Westinghouse Machine Company. He conducted experimental work on large double-acting gas engines and had charge of the construction of gas-electric power plants for the Winchester Repeating Arms Company of New Haven, the Atlantic Refining Company, Philadelphia, and other companies, and for the Pennsylvania State College, where he also was instructor for about three months in gas engineering. During this period he designed a combined governing and lubricating system for the Westinghouse gas engines. For two years after leaving the Westinghouse Company, he was identified with the Roessler & Hasslacher Chem. Co., Perth Amboy, N.J., where he was engineer in charge of the construction of a gas electric power plant extension.

Mr. Knowlton had been associated with the Standard Oil Company since 1913. He had charge of all power apparatus, steam, gas and electric; reconstructed the boiler plants for the company; designed electric drives for new box factory machinery; and introduced new methods of operation and improvements in the boiler and electric plants which resulted in large savings in generating steam and electricity.

Mr. Knowlton had been a member of the A.S.M.E. since 1915.

WINFIELD BRADFORD KNOWLTON

Winfield Bradford Knowlton, supervising engineer of the American Woolen Company, Shawsheen Village, Andover, Mass., died at his home in Andover on February 17, 1931, after a few days' illness. He is survived by his widow, Mrs. Minnie Knowlton, and by one daughter, Marjorie Knowlton.

Mr. Knowlton was born at Lowell, Mass., on May 18, 1877, the son of George Winfield and Etta F. (Watson) Knowlton. He attended the Lowell Textile School and then served an apprenticeship with the Kitson Machine Company and the Tremont & Suffolk Mills, at Lowell. He became connected with the American Woolen Company as draftsman in 1899 and was appointed construction engineer in 1918. He succeeded to the office of supervising engineer of the company on January 1, 1920, taking the place made vacant by the death of William S. Whitney. Among the buildings erected under Mr. Knowlton's supervision were two brick mills at the Assabet Mills, Maynard, a concrete mill and a concrete storehouse at the Riverina Mills, West Medford, two mills and a storehouse at the Washington Mills, Lawrence, two mills, a power house, and a ten-story warehouse at the Shawsheen Mills, and a number of structures in Shawsheen Village, including an administration building. He also supervised the construction of the Andover Country Club House.

Mr. Knowlton became a member of the A.S.M.E. in 1912. He belonged to the Andover (Mass.) Country Club and was a thirty-second degree Mason.

FREDERICK GOTTHOLD KRETSCHMER

Frederick Gotthold Kretschmer, whose death occurred on June 14, 1931, was born at Stuttgart, Germany, on May 15, 1862. He studied classical languages and mathematics at the Realgymnasium in that city, and later attended the Baugewerkschule there. He came to the United States in 1881 and secured his early shop experience with R. Hoe & Company, New York, N.Y. In 1893 he represented F. Krupp of Essen, at the Chicago exposition. The following year he became manager of the New York office of the Brown & Sharpe Mfg. Co. of Providence, R.I.

Mr. Kretschmer returned to Europe in 1897 as representative of the Brown & Sharpe Mfg. Co. In 1899 he was appointed technical manager of Gustav Diechmann & Son, in Berlin, agents, not only

for the Brown & Sharpe Mfg. Co., but also for the Pratt & Whitney Co., Niles-Bement-Pond Company, and many other American manufacturers. From 1901 to 1905 he represented the Bergmann Electrical Works in London.

F. G. Kretschmer & Co. was formed in 1905 at Frankfort on the Main, acting as agents for the Brown & Sharpe Mfg. Co., the Pratt & Whitney Co., the King Machine Tool Company, of Cincinnati, Ohio, and other American manufacturers. In 1912 the firm became agent for the Taylor Manufacturing Company of Philadelphia, in Continental Europe. Several other American machine-tool builders enjoyed representation by Mr. Kretschmer.

As agent for these American companies Mr. Kretschmer specialized in the practical and commercial end of the machine tool business, introducing new machines and methods throughout Europe. He had contributed a number of articles on machine tool industry to the technical press.

Mr. Kretschmer became an associate of the A.S.M.E. in 1895. He resigned his membership in 1908 but was reinstated in 1913. He was transferred to the grade of full membership in 1928. He was also a member of the Verein Deutscher Ingenieure and Verein Deutscher Giesserei-Fachleute. He is survived by his widow, Mrs. Linda Kretschmer.

JAMES B. LADD

James B. Ladd, the son of William W. Ladd and Sarah H. (Phillips) Ladd, was born at Througe Neck, Westchester County, N.Y., on June 27, 1860. He was given an M.E. degree by the Stevens Institute of Technology in 1881. He spent the next six years as draftsman and mechanical engineer for the Southwark Foundry & Machine Co. of Philadelphia. From 1887 to 1890 he was chief engineer in charge of design and construction of the Maryland Extension of the Pennsylvania Steel Company at Sparrows Point, Md. This company was later known as the Maryland Steel Company and is now part of the Bethlehem Steel Company. Mr. Ladd resigned his position with the company in 1890 to become chief engineer for the Robert Poole & Son Co. of Baltimore, with whom he remained for six years. Ill health caused his retirement from active business for about two years, after which he opened an office in Philadelphia for consulting work.

Mr. Ladd became a member of the A.S.M.E. in 1884. He was married in 1889 to Rebecca H. Serrill, of Darby, Pa., who died in 1927. One daughter, Frances (Ladd) Keicher, survives him.

GEORGE CRAMTON LAMMERT

George Cramton Lammert died at Oak Park, Ill., on October 25, 1931, after a month's illness. Since his graduation from the Massachussets Institute of Technology with a B.S. degree in 1927, he had been associated with his father in the engraving and engineering business of Lammert & Mann, Chicago, Ill.

Mr. Lammert was born in Chicago on December 24, 1903, the son of Ferdinand E. and Florence J. Lammert. He secured his preparatory education at the Culver Military Academy. He is survived by his widow, Eleanor (Danker) Lammert, and infant daughter, Barbara.

A. ARCHER LANDON

A. Archer Landon, president since 1925 of the Landon Radiator Co., Inc., died on January 5, 1930. He is survived by his widow, Emma J. Landon, whom he married in 1891, and by one married daughter, Mrs. Hilda (Landon) Conant, of Dedham, Mass.

Mr. Landon was born at Detroit, Mich., on February 5, 1868, the son of John Mason and Melvina (Akerman) Landon. He supplemented his education in common and evening schools with an apprenticeship as a machinist with the Detroit Bolt & Nut Corp. After the completion of his apprenticeship in 1887, he was employed by the American Radiator Company, serving successively as foreman of the machine shop, toolmaker, and superintendent of its Kalamazoo plant, manager of its Titusville plant, assistant manager of its Pierce plant, general superintendent of plants, and vice-president. He was located at Buffalo, N.Y., from 1902 until 1930, with the exception of four years (1905–1909), when he was general superintendent of the manufacturing department in Chicago.

Mr. Landon was a member of several clubs in Buffalo and vicinity, and during the World War was connected with its Chamber of Commerce. He became a member of the A.S.M.E. in 1902. He was a member of President Wilson's Industrial Conference Board and chief of aircraft production of the National Industrial Conference Board. He was active in organizing War Labor Boards.

A number of United States patents, as well as many in England, Germany, France, and Italy, were taken out in Mr. Landon's name and assigned to the American Radiator Company, the Crane Company, and Kalamazoo Spring & Axle Co. These included radiators and radiator sections, molding and casting machines, ramming and heating apparatus, pneumatic tongs, and other equipment.

OLIN HENRY LANDRETH

Olin Henry Landreth, consulting engineer of New York, died of pneumonia on November 6, 1931. He is survived by two daughters, with one of whom he made his home in Mount Vernon, N.Y., and by a son.

Professor Landreth was born at Addison, N.Y., on July 21, 1852, the son of the Reverend James and Adelia (Comstock) Landreth. He attended academies at Pen Yan, Dundee, and Canisteo, N.Y. He then entered Union College, from which he received a C.E. degree in 1876, A.B. in 1877, A.M. in 1880, and honorary D.Sc. in 1905.

During college vacations Professor Landreth secured some early experience in various railway positions and in making surveys and estimates for water works at Schenectady and Olean, N.Y. He was an instructor in the physical laboratory at Union College in 1876 and 1877, professor of civil engineering at Vanderbilt University from 1879 to 1894, and dean of the engineering department, which he initiated there, from 1886 to 1894. He then returned to Union College as professor of engineering, remaining there until 1919. Since that date he engaged in consulting engineering in New York. He was also chief engineer of the Eastern Potash Corporation from 1919 to 1921.

While at Vanderbilt University, Professor Landreth was superintendent of buildings and grounds for about eight years, in charge of new construction and the maintenance and operation of water supply, sewerage, and steam heating systems. He also made surveys, estimates, and investigations for railroads, water works, and electric light systems in several southern cities. He served as consulting engineer to the Board of Public Works in Nashville from 1883 to 1885. He was consulting engineer to the Davidson Company, the Tennessee Bridge Commission, the West Nashville Water Company, and the Tennessee State Board of Health. He made examinations and reports on smoke prevention and on the sanitary effect of the construction of proposed locks and dams on the Cumberland River. In 1893 he served as special commissioner to the World's Fair in Chicago.

After returning to New York, Professor Landreth served as consulting engineer to the New York State Board of Health from 1896 to 1901 and for five years thereafter was connected with the State Department of Health. He was a member of the New York State Water Storage Commission in 1902 and 1903, the New York Bay Pollution Commission from 1903 to 1905, and the Metropolitan Sewage Commission of New York from 1906 to 1908.

Professor Landreth was assistant astronomer at the Dudley Observatory at Albany from 1877 to 1879 and had charge of the expedition to the Helderbergs in May, 1878, to observe the transit of Mercury. In 1882, he was in charge of the Vanderbilt Observatory during the transit of Venus. He was a member of the Advisory Council of the Chicago Engineering Congress in 1893 and had served on the New York State Waterways Association, the Merchants' Association of New York, and various committees on waterways, water storage, sanitation, and public health. He was a delegate to the New York State Constitutional Convention in 1915.

Professor Landreth had contributed papers to the technical press and before various engineering organizations on a wide range of subjects. He was the author of Instructions for Finding the True Meridian, With Tables for Surveyors and of Metric Conversion Tables for Engineers. He collated the civil engineering terms for the last edition of the Century Dictionary. During the World War he served as mechanical engineer in the Ordnance Department at Washington, D.C.

Professor Landreth became a member of the A.S.M.E. in 1883 and served as vice-president of the Society in 1885 and 1886. He was past-president of the American Society for Testing Materials, past director of the American Society of Civil Engineers and of the Society for the Promotion of Engineering Education, a member of the Council of the American Institute of Consulting Engineers from 1923 to 1926, past secretary of the Engineering Association of the South, past-president of the Society of Engineers of Eastern New York, and past vice-president of the American Association for the Advancement of Science.

Professor Landreth married Eliza Taylor at Canisteo, N.Y., in 1879.

GIFFORD LECLEAR

Gifford LeClear, a member of the A.S.M.E. since 1927, died on September 24, 1931, in Boston, Mass. Mr. LeClear was born at

Rutherford, N.J., on January 3, 1874. His parents were Thomas and Cornelia (King) LeClear. He received an A.B. degree from Harvard University in 1895 and his master's degree the following year. He then worked for a year in various capacities for the West End Railroad now the Boston Elevated Railroad. In 1897 he formed a partnership with Edward D. Densmore under the firm name of Densmore and LeClear. The work of the firm was initially confined to small engineering work, later developing into larger work and ultimately into a combined practice of engineering and architecture. Mr. H. C. Robbins was latter admitted to the firm, the name of which became Densmore, LeClear, and Robbins.

This firm, aside from a large architectural practice, has been connected with the installation of power plants, heating and ventilating systems, electrical and refrigeration equipment, and steam transmission systems for many building projects in Boston and vicinity as well as in other cities.

Among its clients have been the New England Telephone & Telegraph Co., The American Telephone & Telegraph Co.; The Massachusetts General Hospital, the Boston City Hospital, Newton Hospital, Beth Israel Hospital; Harvard University, Simmons College, Smith College, Williams College; Boston & Albany, Boston & Maine, and New York, New Haven & Hartford railroads; and many other private, municipal, and state interests. For a number of years the firm acted as consulting engineers for the Mutual Boiler Insurance Company of Boston.

Mr. LeClear was chairman of the Elevator Board for the state of Massachusetts for two years and in that capacity prepared one of the first standard sets of rules and regulations for elevators. He lectured at Harvard University on mechanical plants of buildings, power plants, etc. He also lectured at the Harvard Business School and Massachusetts Institute of Technology on power plant work.

For a number of years he was the chairman of the Traffic Committee of the Boston Chamber of Commerce, and as such was responsible for many of the early developments in signal control in the city of Boston.

In 1903 he married Helen Parker of Boston, and their children are Margaret (LeClear) Gray and Donald LeClear.

JOHN GEORGE LEHMAN

John George Lehman, president and general manager of the Bethlehem Foundry & Machine Co., Bethlehem, Pa., died on May 14, 1931.

Mr. Lehman was born in Bethlehem on January 15, 1874, the son of Bernhard E. and Harriet M. (Fetter) Lehman. He prepared for Lehigh University at the Moravian Preparatory School in Bethlehem, and began the mechanical engineering course at Lehigh in 1892. Following his graduation in 1896, he devoted himself to the operation of the brass foundry and machine shop which his father, who died in 1892, had owned. This foundry was established in 1832 by his grandfather. He sold the business in 1902 to the Bethlehem Steel Company and entered its employ as superintendent of its first brass foundry department, the layout for which was made by him.

Mr. Lehman became identified with the Bethlehem Foundry & Machine Co. in 1906, when it took over the old brass works plant. His work included the development of new designs of apparatus as applied to the chemical industry for the production of acids, dyes, and inorganic compounds, the development of special irons for use in such apparatus to resist chemical action, and the development of machinery for cement plants. He was in direct charge of all sales and all operating departments of the company.

In addition to the A.S.M.E., which he joined in 1921, Mr. Lehman belonged to the American Iron and Steel Institute.

He is survived by his widow, Emily M. (Myers Fuller) Lehman, whom he married in 1918.

WARREN B. LEWIS

Warren B. Lewis, consulting engineer of Providence, R.I., who for the last 35 years had specialized in the design and operation of industrial power plants, died on July 18, 1931.

Mr. Lewis was born at Providence on April 10, 1870, the son of Mr. and Mrs. George W. Lewis. After completing his course at the English High School in that city, he worked in the laboratory at Cornell University with Prof. W. A. Anthony on mechanical and electrical problems. He then spent two years in the experimental department of the Thomson Electric Welding Company, Lynn, Mass., two years in the district engineer's office of the General Electric Company, and one year as manager of central stations for the United Traction & Electric Co.

In 1896 he opened his own office in Providence as a consultant on power plant problems.

He was interested both in the design and construction of industrial power plants and in the efficiency of their operation, in connection with which he studied processes, equipment, and personnel. He had contributed a number of articles on these subjects to the technical press.

Mr. Lewis became a member of the A.S.M.E. in 1915 and also belonged to the American Institute of Electrical Engineers and the Providence Engineering Society. Surviving him are his widow, Lela V. (Hutton) Lewis, whom he married in 1901, and three daughters.

LEROY N. LIEBERKNECHT

Leroy N. Lieberknecht was born at Letts, Iowa, on April 6, 1895, and died on March 13, 1931, at Beloit, Wis. His parents were Henry and Salome (Wiedenecht) Lieberknecht. He received his education in the public schools of Iowa. His work at Iowa State College was dropped that he might enlist for service in the U.S. Army during the World War. After being honorably discharged from Camp Dodge, Iowa, he completed his college work, being graduated from the engineering school at Ames in 1920. He was a member of Tau Beta Pi, honorary engineering fraternity, and of Theta Nu Epsilon.

Following his graduation he accepted a position with Fairbanks, Morse & Co. at Beloit. For several years he was engaged in testing and development work in the Experimental Department, and at the time of his death was head shipping inspector in the Large Engine Department. He had been an associate member of the A.S.M.E. since 1926.

He is survived by his widow, Frances (Newell) Lieberknecht, whom he married in 1923, and by three daughters.

HENRY P. LUDEWIG

Henry P. Ludewig was killed in an airplane crash at the Thornburg Country Club, Pittsburgh, Pa., on June 6, 1931. He had been an associate member of the A.S.M.E. since 1930.

Mr. Ludewig was born in New York, N.Y., on September 19, 1897. He took courses in mathematics, drafting, and engineering in evening trade schools. From 1918 to 1920 he was in charge of the development of moving picture apparatus for the Daylight Film Corporation, New York. During the next five years he was plant superintendent in charge of all tooling, designing, and production connected with an adding machine for the Type Adder Corporation, New York. He then spent three years as salesman of lubricating oils and greases for the Vacuum Oil Company, New York, and a year as salesman of plain and fabricated steel for Egleston Bros. & Co., Inc., Long Island City, N.Y. Since 1929 he had been sales engineer for the Carboloy Co., Inc., Pittsburgh, Pa. His duties included the analysis of jobs and the design of tools to speed production.

Mr. Ludewig is survived by his widow, Olive Marguerite (Hansen) Ludewig, whom he married in 1922.

CHARLES W. LUHR

Charles W. Luhr died suddenly at his home in West Orange, N.J., on December 21, 1930. He is survived by his widow, Kathryn (Drudy) Luhr, whom he married in 1903, and by three sons and a daughter.

Mr. Luhr was born at Ober Ingelheim, Germany, on November 15, 1873, the son of John and Elizabeth (Buchenhauer) Luhr. His education was obtained in the United States where he attended public and private schools and Cooper Union, New York, N.Y. In 1887 he was apprenticed to Hugo Kayser, New York, where he was engaged in experimental work and in making models and special machinery. After two years with Mr. Kayser, he was apprenticed to the Western Electric Company, New York, on telephone and telegraph instrument and switchboards, and also in 1889 was employed by the Standard Cash Register Company of Orange, N.J.

Mr. Luhr's first association with the Edison interests was in June, 1889, in the Edison Phonograph Works at West Orange, where he was employed in the manufacture of phonographs until 1903. He was then promoted to the position of foreman with the Edison Manufacturing Company, making electro-therapeutic instruments, X-ray apparatus, fan motors, moving picture machines, and other special appliances. In 1911 he was made foreman of the second floor of Mr. Edison's laboratory, engaged in experimental and precision work. Two years later he was made superintendent of the laboratory in charge of all work, under the immediate direction of Mr. Edison, and in 1917 was promoted to the vice-presidency and general managership of the Edison Phonograph Works, a position which he occupied at the time of his death.

During the early days of the motion picture industry, Mr. Luhr was

instrumental in perfecting and improving projecting machines. He also helped to perfect the first apparatus for laboratory development and projections of the motion picture film now known as the 16 MM. and, in conjunction with Adolph Gall, perfected the first daylight printing machine for the use of the Edison home kinetoscope. He was granted a patent for a machine for shaving sound record tablets and various other patents which were turned over to the Edison Company. He read widely on the subject of mechanics, had a thorough knowledge of higher mathematics, and assisted in solving many mechanical difficulties.

In 1901, at the time of the assassination of President McKinley, Mr. Luhr was sent by Mr. Edison to Buffalo with X-ray instruments to assist physicians in locating the bullet. Mr. Luhr became a member of the A.S.M.E. in 1916. He was president of the Edison Building and Loan Association, a member of the Elks and the Foresters of America, and interested in all civic matters in the Oranges.

FRANK MAGAW MALANY

Frank Magaw Malany, president and general manager of the F. M. Malany Co., New York, N.Y., died in Brooklyn, N.Y., on March 22, 1931.

Mr. Malany was born on August 22, 1882, at Chester, Pa., the son of Magaw and Isabel (Traynor) Malany. He served a five-year apprenticeship in the Seattle Machine, Boiler & Pipe Shop. From 1903 to 1916, with the exception of three years as chief engineer of the Philippine Steamship Company, he belonged to the Army Transport Service, serving in the Philippines, China, France, and on both the Atlantic and Pacific coasts. He received his first chief engineer's license at San Francisco in 1914, and later secured a chief engineer's license for any ocean. He retired from active service with the rank of Captain. From 1916 until 1918 he engaged in the sale of machinery and supplies.

As a Captain in the U.S. Corps of Engineers during the World War, Mr. Malany spent 13 months at Bordeaux, France, in charge of erecting machine shops, pumping stations, and refrigerating plants and repairing steamers arriving at that port. After returning to this country in 1920 he was appointed assistant superintendent engineer by the War Department. For a time he was stationed at Hoboken, N.J., to superintend repairs on transports, and then he directed the construction and conducted trials of ten self-propelled barges for use on the Erie Canal between New York and Buffalo. After the fleet had been put into operation he was assigned as chief engineer in charge of maintenance and repairs on these and other barges.

In 1921 Mr. Malany became connected with the United States Mail Steamship Company with the rating of assistant to Captain O. W. Koester, vice-president in charge of construction and repairs. Mr. Malany directed the reconditioning for passenger service of several steamers used for transport service during the War.

From 1922 to 1924 Mr. Malany was sales engineer for marine machinery and equipment, and represented the firm of Griffin & Cathcart, consulting engineers, as professional observer in such tests as the trial trip of the S.S. *Leviathan*. For two years, beginning in 1924, he was manager of the Marine Department, New York, of the Hagan Corporation, combustion and chemical engineers, Pittsburgh, Pa. He then spent a few years as manufacturers' agent, and in 1927 organized the firm of F. M. Malany Co., Inc. He kept in close touch with marine affairs as head of this company and also as a marine distributor for the Westinghouse Elec. & Mfg. Co.

Mr. Malany became a member of the A.S.M.E. in 1925. He also belonged to the American Society of Naval Architects, the Society of American Military Engineers, and the Reserve Officers' Association of the United States. He was an active member of the Masonic fraternity and belonged to a number of clubs, including the Propellor Club of the United States, Port of New York, and the Marine Square Club, of New York. He was buried in the National Cemetery at Cypress Hills, Brooklyn.

GUSTAV FRANCIS STOVEL MANN

Gustav Francis Stovel Mann, estimator for Harlow Lewis, New York, N.Y., died on March 5, 1931, after a short illness. He is survived by his widow, Gwendolyn L. (Stapleton) Mann, whom he married in 1923.

Mr. Mann was born in Edinburgh, Scotland, on June 16, 1892, the son of Gustav and Agnes (Sinclair) Mann. His technical education was obtained at Vanderbilt University, Nashville, Tenn., from which he received a B.S. degree in 1918. He taught thermodynamics at the university during his last year there.

For a number of years Mr. Mann engaged in shipbuilding. His first experience in this work was secured in the summer of 1917, when he was in charge of hull drafting for two mine sweepers built by the United States at Shooters Island, N.Y. Following the completion of his college work he took charge of hull and engine drafting and routing of materials for the Alabama Dry Dock & Shipbuilding Co., Mobile, Ala. Articles by him on the "Effective Arrangements of Departments in Shipyard Organization" and "Effective Layout of the Fabricating Shop in Shipyards," were published in the November, 1918, and March, 1919, issues, respectively, of *International Marine Engineering*. In August, 1920, the same journal published a paper on "A Method of Estimating Steel Hull Weights," which dealt with the work he did in 1920 for the Bethlehem Shipbuilding Company, Bethlehem, Pa. He also was in charge of fitting out three ships built by that company at Three Rivers, Quebec, Canada. Mr. Mann also worked for a few months in the production department of the Newburgh Shipyards, Inc., was traveling hull inspector for the United States Shipping Board, in the Gulf District, and designed barges for the transportation of fuel oil for the Tidmex Oil Company, Tampico, Mexico.

During part of 1921 and 1922 Mr. Mann was acting division office engineer for the Tennessee State Highway Department and supervised the construction of some Federal Aid roads. He then went to Barahona, Dominican Republic, as surveyor for the West Indies Sugar Finance Corporation. After returning to the United States he was connected successively with the Charles Ward Engineering Works as ship draftsman at the Yedo Yatch Basin, Brooklyn, the Bartlett-Hayward Company, New York, N.Y., as valuation engineer, the New York State Bridge & Tunnel Comm., New York, as assistant engineer, the Bridge Department of the Delaware, Lackawanna & Hudson R.R. Co., Hoboken, N.J., as designer, and from 1927 to 1930 with the New York Central Railroad, New York, as assistant engineer in the design department of that road.

Mr. Mann became an associate-member of the A.S.M.E. in 1923 and also belonged to the National Geographic Society and the Army Ordnance Association.

ARTHUR STENNETT MARTIN

Arthur Stennett Martin, manager of the Firthite Division and of the Engineering Department of the Firth Sterling Steel Company, McKeesport, Pa., with which he had been connected since 1927, died at the Homeopathic Hospital in Pittsburgh on April 21, 1931.

Mr. Martin was born in Elizabeth, N.J., on October 16, 1885, the son of George J. and Norma (Gartz) Martin. He was graduated from the Battan High School in Elizabeth in 1903 and took a commercial course in the Elizabeth Commercial College. He was then employed by the Pennsylvania Railroad in New York, N.Y., resigning to take a position with B. Nicol & Co. He entered Cornell University in 1906 and was graduated in 1910 with an engineering degree. While at Cornell he joined the Theta Xi Fraternity, won his numerals rowing in the Freshman Crew, was a member of the Varsity Crew Squad, and on the Board of the Sibley Journal of Engineering; after graduation he became a director of the Theta Xi Association of Cornell. During summer vacations he had worked in the shops of the Singer Manufacturing Company, Brunsdorf-Miller Tool Company, and Niles-Bement-Pond Co., and he became sales engineer in charge of the New York State territory for the latter company in 1911.

In 1915 he accepted a position as construction superintendent and treasurer of the Moyer Engineering & Construction Co., Brooklyn, N.Y., specializing in the design and erection of reinforced-concrete industrial buildings. While with this company he worked on the reconstruction of the Edison Plant in West Orange after it had been partially destroyed by fire, and among other things he designed and constructed an addition to the R. G. Dunn Printing Plant in Brooklyn.

In 1916 he became associated with Newton C. Failor to form the Failor-Martin Corporation., which represented various machine manufacturers in the New York Metropolitan area. In 1918 he designed and directed the construction of a machine shop for the Virginia Iron Works, Norfolk, Va., and selected and laid out the equipment for it.

The latter part of 1919 the Failor-Martin Corporation sold their machine business and started the manufacture of stainless steel products, specializing in kitchen cutlery. Mr. Martin had entire charge of the manufacturing operations, involving the development of the original equipment and processes. He worked out many new methods and his process of etching was later installed and used in other similar factories. The plant was originally located in Bloomfield, N.J., and later moved to larger quarters in Belleville, N.J.

In 1927 Mr. Martin became associated with the Firth Sterling organization of McKeesport, Pa., and was located in the New York office where he was in charge of advertising and also engaged in the application and heat treatment of stainless steel for industrial purposes, at the same time specializing in super-high-speed steels. In 1929 he went to McKeesport, as the manager of the Engineering

Department and became also manager of the Firthite Division, in charge of the manufacture and sale of tungsten-carbide tools.

Mr. Martin became a member of the A.S.M.E. in 1928. He was also a member of the American Society for Steel Treating, the Masonic fraternity, and the Engineers Club of Montclair, N.J. Surviving Mr. Martin are his widow, Adaline (Moyer) Martin, and two daughters, Clara and Katharine, all of Pittsburgh, Pa.

ALAN RAMSAY McFARLAND

Alan Ramsay McFarland, who died in Syracuse, N.Y., on January 13, 1931, was born in Painesville, Ohio, on May 26, 1870. His parents were Walter and Mary (Ashfield) McFarland. He attended public schools in Oswego, N.Y., and New Haven, Conn., and took a special three-year course in mechanical engineering at Cornell University.

In July, 1891, Mr. McFarland entered the employ of the Solvay Process Company, Syracuse, as assistant to the manager of the Bicarbonate Department. He was made acting manager of that department the following year. During the next 15 years, he was connected with the Soda Ash Department, first as assistant to the manager, and later as manager. From 1907 to 1915, he was works manager of the company, and during the next seven years chief engineer. In 1922 Mr. McFarland accepted a position as chief engineer of the Charcoal Iron Company of America, at Marquette, Mich., where he remained for four years. Since that time he had been connected with the Onondaga Brick & Tile Corp., of Syracuse, N.Y., as president since 1928.

Mr. McFarland became a member of the A.S.M.E. in 1902. He is survived by his widow, Ella (Belden) McFarland, whom he married in 1896, and by two sons and a married daughter.

CLARK YOUNG McGOWN

Clark Young McGown, associated with the Consolidated Gas Company of New York, N.Y., since early in 1929, died on January 17, 1931. He was a native of New York, where he was born on January 9, 1895, the son of Clark Elbert and Ettie McGown. He was graduated from the Stevens Institute of Technology with an M.E. degree in 1916. During the next two years, he was employed by the British Guiana Sugar Factories, Ltd., of Demerara, British Guiana, as second operating engineer in its sugar factory at Plantation Wales. His work during this time included the study of the analysis and chemical control of sugar in the laboratory, and the supervision of factory operation and of overhauling of old machinery and installing new machinery.

During the World War, Mr. McGown served in the Ordnance Department of the Army, being stationed at Camp Hancock, Ga. He re-entered the employ of the British Guiana Sugar Factories as chief engineer in 1919 and remained there for two years. He then returned to the United States as inspection foreman for the Western Electric Company in Newark, N.J. The following year he became superintendent of shops and the commercial distribution departments of the Northern Union Gas Company in the Bronx, N.Y., a position which he held until he became affiliated with the Consolidated Gas Company in 1929.

Mr. McGown's first position with the Consolidated Gas Company was that of superintendent of the Utilization Laboratory and of the Refrigeration and Maintenance Departments. Later, he took charge of two warehouses and fleets of trucks handling appliances for the company. In 1929 he was given the position of engineer of utilization, supervising these various departments.

During his connection with the British Guiana Sugar Factories, Mr. McGown designed a new link belt chain carrier for conveying sugar cane from an unloading platform into the mill, and other equipment for the company.

Mr. McGown was a student member of the A.S.M.E. while at the Stevens Institute of Technology and in 1918 became a junior member of the Society. He was promoted to the grade of associate membership in 1922 and to full membership in 1930. He also belonged to the American Gas association and the Masonic fraternity.

Surviving Mr. McGown are his widow, Mildred (Burr) McGown, whom he married in 1919, and two sons, Kenneth and Donald.

ELWOOD FRANCIS McLAUGHLIN

Elwood Francis McLaughlin, for twenty-five years connected with the General Electric Company, died on January 8, 1931, at Atlanta, Ga. Mr. McLaughlin was born in Philadelphia, Pa., on October 4, 1883. He was graduated from the Pennsylvania State College in 1905 with the degree of B.S. in Mechanical Engineering.

Following his graduation, Mr. McLaughlin spent five years with the General Electric Company at Lynn, Mass. Here he had experience in the Steam Turbine Testing Department and the Designing Department, was for two years chief computer for the company, and served as assistant engineer for more than a year. He was then transferred to the Railway and Lighting Department of the Company at Atlanta. For a number of years he represented the company, both in an engineering and commercial capacity, in connection with the sale and installation of steam turbines and electrical equipment for central stations. Much of his time was also devoted to the study of transportation conditions and the requirements of street railway companies in cities throughout the entire Atlanta district, which comprised all the southeastern states.

At the time of his death Mr. McLaughlin was district manager of the Central Station Department of the General Electric Company at Atlanta.

Mr. McLaughlin became a member of the A.S.M.E. in 1919. He is survived by his widow, his daughter, Dorothy F. McLaughlin, two sons, James A. and Elwood F. McLaughlin, Jr., all of Atlanta, and by his mother, Mrs. James F. McLaughlin, of Philadelphia, Pa.

NATHAN ATHERTON MIDDLETON

Nathan Atherton Middleton, of Middleton & Co., Inc., Cleveland, Ohio, died on May 4, 1931. He was born at Louisville, Ky., on February 28, 1887, the son of Harvey and Cornelia Speake (Scribner) Middleton. He was graduated from the Massachussetts Institute of Technology with an S.B. degree in mechanical engineering in 1907 and during the next two years was a special apprentice in the machine and erecting shops of the American Locomotive Company, Richmond, Va. In 1908–1909 he was an assistant in the foundry of Bartlett-Hayward Company, Baltimore Md., following which he spent two years with the Thos. C. Basshor Co. of that city, designing boilers and special machinery and during part of the time serving as general superintendent of the boiler and machine departments.

In 1911 the Whiting-Middleton Construction Company, Baltimore, was organized to handle concrete sewer, bridge, and road construction, with Mr. Middleton as its president. Two years later it was reorganized as the Middleton-Thompson Company, and continued in business until 1915. After engaging in consulting work covering valuation reports for the Western Union Telegraph Company and factory investigations for the Boston Confectionery Company, Cambridge, Mr. Middleton accepted a position with Hornblower & Weeks, Boston, as engineer in charge of the investigations and reports regarding industrial corporations which that company financed or proposed to finance. He also represented the company on the boards of directors of its clients and served a number of companies as consulting engineer, designing and constructing additions and improvements in the plants of the Parish & Bingham Corp. and Ohio Body & Blower Co., Cleveland, Mullins Body Corporation, Salem, Ohio, Will & Baumer Co., Syracuse, N.Y., Lee Tire & Rubber Co., Conshohocken, Pa., and Atlas Tack Company, Fairhaven, Mass.

In 1922 Mr. Middleton went to Cleveland, continuing his connection with Hornblower & Weeks and at the same time serving as president of the Ohio Body & Blower Co. The following year he was made president of the Cleveland Windshield Company. He severed these connections in 1927 when he became a partner in the firm of Middleton, Eden & Co., Cleveland. This company was reorganized the following year as Middleton, Worthington & Co., Inc., and shortly before Mr. Middleton's death became Middleton & Co., Inc. Mr. Middleton had also been director of the Swartout Company, Cleveland.

Mr. Middleton was commissioned a captain in the 23d Engineers in 1917, and in 1918 and 1919 was a major, commanding the 3d Battalion, 23d Engineers, in France, and was also regimental adjutant. He worked on the design and construction of army railroad yards and storage depots for munitions, and during the Argonne-Meuse Offensive served as executive officer of the engineer of roads, First Army, in charge of all road construction of the Army. After the Armistice until the end of May, 1919, he had entire charge of all engineering work in the Second Army area. He also was regimental historian.

Mr. Middleton was elected an associate member of the A.S.M.E. in 1917 and was promoted to full membership three years later. He belonged also to the American Society of Military Engineers and a number of clubs in Boston, New York, and Cleveland. He married Mina Winslow DeHart in 1913 and is survived by her.

WALTER MILLER

Walter Miller, a member of the A.S.M.E. since 1886, died on February 26, 1930. Mr. Miller was born in Scotland. He learned the machinist's trade, after which he worked for three years at Springfield, Ohio, as draftsman for Whiteley, Fassler & Kelley. He then held a similar position for six years at the Globe Iron Works in

Cleveland, and from then until his retirement conducted a consulting practice as a mechanical engineer in Cleveland. Since his retirement from active business he had made his home at Painesville, Ohio.

THOMAS WILLIAM MILNOR

Thomas William Milnor, president of the Kline Hardware Company, Inc., Allentown, Pa., since 1913, died on November 12, 1930. He was born at Burlington, N.J., on October 27, 1866. He attended Stevens Institute of Technology and was graduated with a degree in mechanical engineering from Cornell University in 1889. His early practical experience was secured as special apprentice at the Jeansville Iron Works of the J. C. Haydon & Co.

Following his graduation, Mr. Milnor was employed by the Link-Belt Engineering Company for two years, and by the McNeal Pipe & Foundry Co. of Burlington, N.J., as superintendent in 1893. During the next five years, he managed his father's coal business and designed and built a plant for the Sanitary Enameled Clay Company, in Burlington, for the manufacture of enameled bricks. From 1899 to 1903, he was connected with the Borgner Cement Company and interested in firebrick. He accepted the office of treasurer for the Mickle-Milnor Engineering Company of Philadelphia in 1903. This company was devoted to the selling of radial brick chimneys, air compressors, and Corliss engines. From then until the establishment of the Kline Hardware Company, Mr. Milnor was associated with the Donaldson Iron Company of Emaus, Pa., engaged in the design and construction of their pipe foundry plant.

Mr. Miller became a member of the A.S.M.E. in 1915.

HARRY MORTIMER MONTGOMERY

Harry Mortimer Montgomery, retired mechanical engineer, died suddenly on February 24, 1931, of a heart attack, at his home in Evanston, Ill.

Mr. Montgomery was born in Lafayette, Ind., on July 28, 1861, the son of Henry and Estelle Helène (Von Flierden) Montgomery. He took a special course in mechanics at the Massachusetts Institute of Technology from 1877 to 1879, and then spent three years as apprentice and draftsman in the locomotive shops of the New York & New England R.R., at Readville and Norwood, Mass. During 1882 and 1883 he was engaged by the Hinkley Locomotive Works, Boston, to make detail drawings of locomotives and to erect them at Culebra for the Compagnie Universelle du Canal Interoceanique. Returning to this country upon the completion of this work, Mr. Montgomery became chief draftsman for the Rhode Island Locomotive Works, Providence, R.I. After a short time with this company he accepted a similar position with the New York, Lake Erie & Western R.R., being stationed at the Susquehanna, Pa., locomotive shops.

Mr. Montgomery returned to New England in 1885 to take charge of the design of locomotives, passenger and freight cars, and machine tools for the New York & New England R.R., at Norwood, and also had charge of the drafting office, pattern shop, and brass foundry. After six years in this position he was engaged for about a year each by the Boston Bridge Company, Boston, Morton Safety Car Heating Company, Baltimore, Md., Babcock & Wilcox Co., New York, N.Y., A. C. Frost & Co., Chicago, Ill., and Munoz Boiler Company, New York, N.Y. His work for these companies related to design and construction, and, in the case of Babcock & Wilcox, reorganization of the drafting office and force and systemization of drawings and other engineering records.

After a few years as manufacturer's agent in New York, Mr. Montgomery went to Chicago in 1905 as manager of the Alberger Condenser company. Upon its reorganization under the name of the Alberger Pump & Condenser Co., in 1913, he was appointed district manager. He retired from this position the following year to become a member of the firm of Humphrey and Montgomery, Chicago, consulting and constructing engineers. In 1916 and 1917 he designed and superintended the construction of a pulp mill digester house for the Eastern Manufacturing Company, Bangor, Me.

In 1918 Mr. Montgomery entered the U.S. Army as a major in the Quartermaster Corps. He directed the construction of warehouses, water works systems, and a fire engine house at Jeffersonville, Ind., and St. Louis, Mo. After the close of the war he was appointed commissioner of public works and city engineer by the City of Evanston, where he had made his home for some years. He retired from business upon the completion of this service in 1920.

Mr. Montgomery had been a member of the A.S.M.E since 1889. He also belonged to the Engineers' Club in New York, the Chicago Engineers' Club, and the Technology Club. Surviving him are his widow and five children, Helen and Louis W. Montgomery of Evanston, H. M. Montgomery of New York, and Mrs. Herbert G. Clifford and Mrs. Richard M. Illsley of Pasadena, Calif.

J. CLARK MOODY

J. Clark Moody, experimental engineer and head of the experimental department for the Chicago Pneumatic Tool Company, Franklin, Pa., died at Garden City, Kansas, while visiting there on March 14, 1931.

Mr. Moody, the son of Alpheus Phelps and Mary Elizabeth (Wheaton) Moody, was born on August 15, 1893, at Judsonia, Ark. He attended high school at Bald Knob, Ark., and was graduated from the University of Arkansas in 1919, receiving his mechanical engineering degree three years later. His early experience was secured during summer vacations as foreman in charge of locomotive and repair shop equipment on small logging railroads in Arkansas. Following his graduation he secured a position as test engineer with the Chicago Pneumatic Tool Company, Franklin, Pa., his duties including the erection and test of steam, electric, and oil-engine-driven air compressors and Diesel and semi-Diesel oil engines. After four years with this company, he went to Cambridge, Mass., as instructor in the mechanical engineering department of the Harvard Engineering School. He returned to the employ of the Chicago Pneumatic Tool Company after one year at Harvard and remained with it until his death. He had full charge of all experimental work done by the company. His experiments resulted in a number of inventions in the field of pneumatic tools.

Mr. Moody became a member of the A.S.M.E. in 1928 and also belonged to the Pennsylvania Engineering Society and the American Legion. He was in the Coast Artillery Service at Fort Monroe, Va., during part of the World War.

Mr. Moody is survived by his widow, Ruth (Smith) Moody, of Garden City, Kansas, whom he married in 1920.

MILLER F. MOORE

Miller F. Moore, who died of heart failure at Roselle, N.J., on November 29, 1930, was born at Corning, N.Y., on May 29, 1842. His parents were Samuel Lovell and Frances Ann (Armstrong) Moore. He was educated in the public schools and Christ Church School at Elizabeth, N.J. At the age of 19 he entered the employ of Bridges and Lane, New York, N.Y., building and selling machine tools and supplies. After five years with this firm he became secretary and general manager of the Locomotive Engine Safety Truck Company, in New York, where he remained until 1881. At that time he accepted a position as general manager for the Edison Company in New York. In 1884 he was general agent of Armington & Sims Co. for a short time, and during the next 17 years secretary and treasurer of Samuel L. Moore & Sons Co. at their Crescent Ship Yard and Iron Works, Elizabeth, N.J. From 1901 to 1903 he was president of the Marine Engine & Machine Co., Harrison, N.J. He retired in 1904.

Mr. Moore became a member of the A.S.M.E. in 1891 and also belonged to the Naval Architects and Marine Engineers, the Masonic fraternity, and the Machinery and Lawyers Clubs in New York. He is survived by his widow, Helen Serena (Brown) Moore, whom he married in 1867, and by a son and a daughter.

WILLIAM JAMES PERRY MOORE

William James Perry Moore, whose death in Detroit, Mich., on November 2, 1930, was caused by a cerebral hemorrhage, was born in New Britain, Conn., on May 4, 1858. He was the son of James Pericles and Lucy Eliza (Clark) Moore. After completing the dynamical engineering course at the New Britain High School, he entered the Sheffield Scientific School of Yale University which conferred a Ph.B. degree upon him in 1878. After his graduation he was connected for a short time with the New York office of the Buckeye Engine Company of Ohio. From 1883 to 1901 he was in the employ of the Worthington Pump & Machinery Corp. of New York, first as a salesman in the New York office, and later as European representative of the company, with headquarters in London. He established its business in various countries on the Continent, particularly in Russia, and later became vice-president of the company. When the Alberger Pump & Condenser Co. of New York was organized in 1902, Mr. Moore was made its general sales manager. He was connected with the company until 1918, serving in an advisory capacity during the last six years.

Since 1918 Mr. Moore had been engaged independently on the improvement in design of high grade automobiles and trucks. He had made numerous mechanical inventions, expecially relating to automobiles, and had taken out many patents in England and the United States for vehicle wheels, frames for automobiles, pneumatic tires, radiators, and designs for automobile bodies and chassis. A

number of applications for patents were on file at the Patent Office at the time of his death.

Mr. Moore entered the A.S.M.E. as a junior member in 1885 and became a member a few years later. He withdrew from membership in 1908 and was reinstated in 1912. He is survived by his widow, Mary Anastasia (Tobin) Moore, whom he married in Jersey City, N.J., in 1906.

GUSTAV MORTENSEN

Gustav Mortensen, production and sales engineer for the Giant Heating Company, Los Angeles, Calif., since 1928, died in National City, Calif., on August 3, 1930. Mr. Mortensen was born in Copenhagen, Denmark, October 4, 1895, the son of Frederik L. P. and Nicoline H. (Hansen) Mortensen. He spent four years at De Forenede Kirkeskoler in Copenhagen, and received a B.A. degree in mechanical and electrical engineering from the Teknisk Selskabs Skole of that city in 1917. For two years following his graduation, he was connected as mechanical engineer and draftsman with F. L. Smith & Co. of Copenhagen, engaged in the design of cement mill machinery and general plant layout. During the following year he was employed by Riedel & Lindegaard of that city as mechanical engineer on the design of steam power plants, engines, cranes, and general machinery.

Mr. Mortensen came to the United States late in 1920 and was employed for two years as mechanical draftsman by the Holt Manufacturing Company, Stockton, Calif., manufacturers of caterpillar tractors and power harvesters. During the next two years he was connected with S. G. Fyfe, consulting engineer of Los Angeles, in the design and supervision of boiler, heating, and ventilating plants. For a short time in 1924 he designed marine and stationary steam power plants for the Liberty Boiler Works of Los Angeles. In October of that year he entered the employ of the Pan American Oil Company of Wilmington, Calif., to design oil refinery equipment. After two years with this company he became associated with the Summerbell Truss Company of Los Angeles as structural engineer, and subsequently worked as designer and served as general manager of its Oakland, Calif., office. He resigned this position in 1928 to accept the one which he held at the time of his death.

Mr. Mortensen became an associate member of the A.S.M.E. in 1930. He also belonged to the Ingenior & Konstructor Sammenslutningen of Copenhagen. He was an enthusiastic yachtsman, belonging to an amateur yacht club in Copenhagen for many years and receiving many trophies there, and serving as manager and president of the Viking Athletic Club of Los Angeles from 1924 to 1928. A brother, Karl Mortensen, of Los Angeles, survives him.

JOHN JAMIESON MUIR

John Jamieson Muir, who died on April 7, 1931, at the Providence Hospital in Seattle, Wash., was a native of Ireland. He was born at Waterford on May 4, 1860, the son of Alexander and Marion (Jamieson) Muir. He studied steam engineering and applied mechanics at the College of Fine Arts in Glasgow, and served an apprenticeship from 1875 to 1880 with the Muir and Huston Harbour Engine Works in that city. His first position was as assistant engineer for the Transatlantic State Line on the S.S. *Craigrownie*. In 1882 he entered the drawing room of the Fairfield Works of John Elder & Co., at Govan, Scotland, where he remained for about a year. The next four years were spent as engineer and superintendent with MacNicoll & Co., naval architects of Glasgow. He then went to Calcutta as deputy superintending engineer for the India General Steam Navigation Company. From 1890 to 1892 he was assistant manager for John King & Co., shipbuilders and general contractors, Howrah, Bengal, East India.

Mr. Muir came to the United States in 1893 and for two years was associated with the Fort Wayne Electric Corporation, Fort Wayne, Ind., as engineer and draftsman. For four years beginning in 1896, he was chief draftsman for the Bass Foundry and Machine works of Fort Wayne, and manager for the following year of the National Steel Casting Company of that city. He went to Pittsburgh, Pa., in 1903, and during the next year worked for the Engineering Sun Company of Marcus Hook, Pa., as marine engineer and superintendent. He returned to Fort Wayne in 1905, and after some general engineering work there, again went to Pittsburgh to work for the American Sheet & Tin Plate Co. From 1908 to 1918 he was mechanical superintendent of the Bass Foundry and Machine Works at Fort Wayne, with which he had earlier been connected as chief draftsman. He had been located in Seattle since 1919, for a year as superintendent of the Patterson-MacDonald Shipbuilding Company, after which he retired, except for some consulting work.

Mr. Muir became a member of the A.S.M.E. in 1896. He is survived by three daughters. His wife, Elizabeth (White) Muir, also died in 1931.

AUGUSTUS F. NAGLE

Augustus F. Nagle, who became a member of the A.S.M.E. in 1880, died at the Brooklyn Home for Aged Men, in Brooklyn, N.Y., on December 5, 1920. He entered the Home in June of that year.

HOWARD B. NASH

Howard B. Nash, who died on July 5, 1931, had been chief engineer of the Armour Leather Company, Chicago, Ill., since 1914. He had charge of the design, construction, and maintenance of a large number of industrial plants, as well as the selection and purchase of equipment for them.

Mr. Nash was born at Platte City, Mo., on June 7, 1884, the son of William and Annie Nash. He was graduated from the Manual Training High School at Kansas City, Mo., and studied mechanical engineering through the International Correspondence Schools, day classes at the Chicago School of Technology, and night classes at Armour Institute. He learned the machinist's trade with Swift & Company at Kansas City and the Atchison, Topeka & Santa Fé Railroad at Argentine, Kansas. He worked as a machinist for a year for Armour & Company of Kansas City and for the St. Louis & Santa Fé Railroad, for which he subsequently became roundhouse foreman at Enid, Okla. In 1909 he served as floor foreman at Kansas City for the Kansas City Terminal Railroad. The following year, he went to Indiana Harbor as draftsman for the American Steel Foundry. In 1910 he accepted a similar position at the Armour Glue and Soap Works in Chicago, being promoted from that position to the one which he held at the time of his death.

Mr. Nash became a member of the A.S.M.E. in 1921. Surviving him are his widow, Rose M. (Kill) Nash, whom he married in 1918, and three children, Howard B., Marjorie M., and Catherine A. Nash.

EMIL ARTHUR NELSON

Emil Arthur Nelson, who died on January 10, 1931, at Springfield, Ill., after a brief illness, was born at Reading, Pa., on June 14, 1894. His parents were Adolph and Edna Nelson. He was educated in Sweden, at the Ostersund High School and the Royal Technical University, Stockholm, from which he received his M E. degree in 1921. During the summer before his graduation he was employed as a designer for the Swedish State Railways, with whom he had served an apprenticeship and worked as a machinist at an earlier time. He had also been employed as an estimator at the Stockholm Machine Shop during one vacation.

Mr. Nelson returned to the United States in 1921 and for a year was machinist and acting shop draftsman for the Long Island Railroad. During the next two years he was draftsman for the Babcock & Wilcox Co., at Bayonne, N.J., working in their proposal department on standardization and other developments. He had been with the Springfield Boiler Company as mechanical engineer from 1924 until the last year of his life, during which he was combustion engineer for the Municipal Light and Water Department of Springfield.

Surviving Mr. Nelson are his widow, Caroline M. (Bretscher) Nelson, whom he married in 1926, and an infant daughter. Mr. Nelson had been an associate member of the A.S.M.E. since 1929.

ALMON EVANS NORRIS

Almon Evans Norris, for many years chief engineer for the Mead-Morrison Manufacturing Company, and prior to that mechanical engineer for its predecessor, the Rawson & Morrison Manufacturing Co., died on January 15, 1931, at his home in Brookline, Mass.

Mr. Norris was born at Orford, N.H., on May 29, 1866, the son of John Langdon and Martha (Evans) Norris. He received an S.B. degree in mechanical engineering from the Massachusetts Institute of Technology in 1890. Following his graduation he spent several years in the drawing-room of Edward Kendall & Sons, Cambridgeport, Mass., with whom he had secured his first experience as a machinist before entering M.I.T. This company were builders of hoisting engines. He was later associated with the Leavett Engineering Company for about three years.

Mr. Norris also had some early work in the design of telescope mountings for Alvan Clark & Sons, including the Bruce photographic telescope for Harvard University and a 24-in. telescope for Lowell's Observatory at Flagstaff, Ariz. The telescope mountings for Harvard University were built at the factory of Rawson & Morrison.

The Rawson & Morrison Manufacturing Co., with which Mr. Norris became associated in 1896, manufactured hoisting engines and machinery and automatic coal handling machinery. It was located at Cambridgeport at that time. The company was reorganized in 1904 as the Mead-Morrison Manufacturing Company and

moved to East Boston in 1913. Mr. Norris was their chief engineer from the date of their organization until the time of his death. He was responsible for the machinery manufactured by them, and was considered a peer in their field of specialized engineering.

Mr. Norris became a member of the A.S.M.E. in 1900. Surviving him are his second wife, Maud F. (Conrad) Norris, whom he married in 1905, and five daughters and a son.

WILLIAM TULLY NORTON, JR.

William Tully Norton, Jr., died on April 28, 1931, at Lakewood, Ohio. He was born on October 20, 1880, in Cleveland, Ohio, the son of William Tully and Harriet Reid (Haller) Norton. He attended the University School and Case School of Applied Science, both of Cleveland. Prior to this graduation he worked as a draftsman for the General Automobile Company in Cleveland, securing there his first experience in the automotive industry. After completing his work at the Case School in 1903 he was employed for a time by the Cleveland Telephone Company. He then was engaged by Howard E. Coffin of the Olds Motor Works in Detroit, Mich., as experimental engineer and for two years worked on the design and testing of motors. During the next two years he was successively assistant superintendent of the Phoenix Truck Company, Detroit, designer for the Aero Car Company, Detroit, and superintendent of the Kansas City Motor Car Company, Kansas City, Mo. From 1908 to 1910 he was chief inspector for the Chalmers Motor Company, of Detroit. He organized the inspection department of the company and had supervision of the testing and chemical laboratories, controlling inspection of raw material, finished machine parts, and completed cars. After leaving the Chalmers Motor Company he did some experimental work for James Cunningham, Son & Co., Rochester, N.Y., and then, in 1911, became chief engineer and general superintendent of the Selden Motor Vehicle Company, Rochester, N.Y. He was connected with this company until 1918, designing trucks and having direct supervision over producing methods and inspection.

Mr. Norton spent several months of 1916 in England and France checking the performance of trucks operating under war conditions. He served in 1916 and 1917 as a member of the Military Truck Committee sponsored by the Society of Automotive Engineers and the National Automobile Chamber of Commerce and cooperating with the Government in the standardization of army trucks. In October, 1917, he supervised the construction in seven days at the Selden factory of a sample Class B or Liberty truck and himself drove it to Washington for delivery and demonstration. In February, 1918, he was sent to France as civilian technical advisor to the chief of the Motor Transport Corps, A.E.F.

From January to June, 1919, Mr. Norton was chief engineer of the Russell Motor Axle Company, of Detroit, Mich., designing a new line of gear driven truck axles, and supervising laboratory and road tests of materials and axles. From June to October of that year he held a similar position with the Republic Motor Truck Company of Alma, Mich. He was then called to Washington as assistant chief engineer of the Motor Transport Corps, subsequently being stationed at Camp Holabird, Md., and Lakewood, Ohio. Since his retirement from that position in 1922 he had been engaged as chief engineer for the L. M. Axle Co., Cleveland, and the Sarasin Six-Wheel Truck Company, Haverhill, Mass., and for the past five years had done consulting work, mostly of a private character for large corporations and banking institutions.

Mr. Norton became a member of the A.S.M.E. in 1920. He also belonged to the Society of Automotive Engineers and to the Masonic, Beta Theta Pi, and Theta Nu Epsilon fraternities. He is survived by his widow, Mildred French (Williams) Norton, whom he married in 1905, and by his mother.

GEORGE MILTON OGLE

George Milton Ogle, who died on October 14, 1931, was born at Louisville, Ky., on February 23, 1891, the son of George J. and Nellie (Lane) Ogle. He was graduated from Vanderbilt University with a B.E. degree in 1912. His college vacations were spent with the Louisville & Nashville R.R., the American Car & Foundry Co., and the Chicago, Rock Island & Pacific Ry. Co. Following his graduation, he spent a year as draftsman in the signal department of the Pennsylvania Railroad at Pittsburgh, Pa. During the next four years he was connected first as chief draftsman and subsequently as superintendent of machinery with the Heywood Bros. & Wakefield Co., Wakefield, Mass. He next spent two years with the Edison Electric Illuminating Company in Boston, as commercial engineer, and a year with the Massachusetts Chocolate Company as mechanical and electrical superintendent. In 1918 he was identified with the Westinghouse Electric & Manufacturing Co., East Pittsburgh, for which he handled rubber, paper, and cement mill electrifications. In 1919 he was chief electrical engineer, division of construction, Northern Atlantic District, U.S. Shipping Board. His duties included the layout of power plants, air compresso plants, etc., necessary for ship construction.

From 1920 to 1922, Mr. Ogle was chief electrical engineer for the Vulcan Iron Works, Jersey City, N.J., specializing on the applications of electrical driven auxiliaries for merchant marine vessels. Under his supervision, the U.S. Shipping Board's S.S. *Eclipse* was electrified. For two years, beginning in 1923, Mr. Ogle was power specialist for the General Electric Company in the New York district, advising salesmen in regard to the proper application of power equipment and economic operation of power plants. From 1925 to 1928 he was consulting power engineer for the General Engineering & Management Corp., New York, N.Y. Since that time he had been manager of the power and industrial department of the National Electric Power Company, New York.

Mr. Ogle joined the A.S.M.E. as a junior in 1921 and attained full membership in 1927. He also belonged to the American Institute of Electrical Engineers and the Society of Terminal Engineers, and he had contributed a number of articles to the technical press. He is survived by his widow, Grace (Kiernan) Ogle, whom he married in 1916, by one son, George M. Ogle, Jr., and by his mother.

WILLIAM POOL PARKER

William Pool Parker, whose death occurred on June 6, 1931, was born at Owosso, Michigan, on May 8, 1871. His parents were Henry Warner and Agnes (Nicholson) Parker. Mr. Parker was graduated from the University of Michigan with a B.S. degree in civil engineering in 1894. During the next six years he worked on the design of bridges for the Keystone Bridge Works of the American Bridge Company and for the Pittsburgh Bridge Company, both of Pittsburgh, Pa., and also for the Massillon Bridge Company of Massillon, Ohio. He obtained experience in the design of foundry equipment with the Whiting Foundry Equipment Company of Harvey, Ill., and in heating and ventilating with the Detroit Heating & Lighting Company of Detroit, Mich. For a time, he was located in the chief engineer's office of the Cambria Steel Company of Johnstown, Pa. Here, he worked on the design of all classes of steel structures.

From 1902 until 1912, Mr. Parker was chief engineer for the A. M. Blodgett Construction Company, Kansas City, Mo. During the last three years, he was in direct charge of the construction of the Galveston Causeway. As a member of the firm of the Concrete Steel Engineering Company of New York, Mr. Parker was connected with the construction of the reinforced-concrete arch bridge over the Mississippi at Minneapolis and the bridge over the Hudson River at Glens Falls, New York.

For five years, beginning in 1915, Mr. Parker was associated with the Keystone State Construction Company, representing the Underpinning & Foundation Co. of New York. He was construction engineer for the City Hall Subway in Philadelphia. After the completion of this work, he became general manager for Ballinger & Perrot, later known as The Ballinger Company. Since 1924 he had engaged in general practice as a consulting structural engineer in Philadelphia.

Mr. Parker became a member of the A.S.M.E. in 1921. He was an honorary member of Tau Beta Pi fraternity, and also belonged to the American Society of Civil Engineers and the Engineering Institute of Canada, as well as to a number of clubs in the vicinity of Philadelphia. He was a former vice-president of the Engineers Club of that city. Mr. Parker served with the Engineers Corps during the Spanish-American War.

Surviving Mr. Parker are his widow, Emilie Whittaker (Evans) Parker, whom he married in Pittsburgh in 1899, and a son and three daughters, Henry Warner Parker, Mrs. Anthony V. Pickard, Mrs. Herman S. Thoenebe, and Emilie Evans Parker.

SIR CHARLES ALGERNON PARSONS

Pioneer in steam-turbine engineering, honorary member of many engineering societies, including The American Society of Mechanical Engineers, and the first engineer to receive the Order of Merit, the Hon. Sir Charles Algernon Parsons died February 11, 1931, while on a cruise to the West Indies. He was 76 years old, and through his death engineering science and industry lost a leader and pioneer. More than any other person, by his development of the steam turbine, he contributed to the greatest advance in steam practice since the advent of the steam engine. He was not the first to conceive of a rotary steam prime mover, but due to his labor and ingenuity the

steam turbine became the prime mover for the generation of electricity in the largest power stations, and for the propulsion of the largest and fastest ships. He had a very broad knowledge of scientific activities, was very sympathetic in his nature, and a most agreeable and interesting companion.

The scientific bent in Sir Charles was in some measure hereditary, and was nurtured under his distinguished father, the Earl of Rosse, of astronomical fame. From his birth, on July 13, 1854, he lived in a scientific environment, for Birr Castle was an open house to men of high achievement. Sir Charles learned the principles of mechanical construction from his father, and also had a succession of distinguished tutors. After a short period at Dublin University he entered St. John's College, Cambridge, at the age of 19. His three-year course terminated with the winning of high honors as eleventh wrangler in the Mathematical Tripos of 1876. He next became pupil apprentice at Armstrong's works at Elswick, where he continued for four years. His brilliance as a scientist and technician thus had a practical foundation, and he attained mechanical skill of a high order. Later in the development of his inventions he was capable of taking the tools from a workman's hand and showing him how to do the job. As an apprentice he invented several things, among which were valve motions and a four-cylinder epicycloidal rotary engine with revolving cylinders which were then manufactured by Messrs. Kitson, of Leeds. It then followed naturally that with the termination of his apprenticeship he should join the latter firm, where he continued for two years, his chief work being on the propulsion of torpedoes by rockets.

In 1883 Sir Charles became a partner in the firm of Clarke, Chapman, and Company, and shortly afterward began experimenting with the steam turbine, about one year after it had been invented by de Laval of Sweden. Sir Charles devised the scheme of compounding the blading, and developed the reaction turbine in which steam flows through a series of alternate stationary and moving blades of similar form. By this arrangement he was able to reduce the speed of the rotor so that higher efficiencies could be obtained at speeds much more practical than had been possible in the de Laval turbines. It was due to this invention and to his subsequent activities that the steam turbine became of such commercial importance and the building of turbines in large sizes was made possible.

The turbine blades at first were milled out of the solid metal on the periphery of brass rings, a construction subsequently superseded by one more perfect, in which the blades were set and wedged with distance pieces in rings with their roots in grooves on the drum and on the casing, as is now a familiar construction. At that time dynamo construction was in its infancy and the speeds necessary had a great influence on the design of the steam turbine and added to the problems that had to be solved. Sir Charles believed that there was a great future for the supply of electricity, and he knew that its generation was then limited and ever would remain so unless the limitations of the reciprocating engine were overcome. He had in mind a prime mover of small dimensions, naturally balanced, which could run at the speeds necessary for efficient dynamos. It was the combination of steam turbine with dynamo that led to his success, and although the first turbine was less efficient than the reciprocating engine, its particular qualities for dynamo driving compensated for the loss. The steam turbine has now entered the entire field of the steam engine, and is the parent of a large family of high-speed devices designed particularly to take advantage of the characteristics which it affords.

The first Parsons steam turbine was completed in 1883. It was a 4-kw. machine with a series of rotating wheels, each complete in itself and corresponding to a parallel-flow water turbine. The mechanical difficulties were great, but they were overcome. The steam consumption of the first turbine was about 200 lb. per kw-hr., with a pressure of only 60 lb. per sq. in. This type of machine continued to be built for six years in small sizes for running dynamos, the largest machine being of only 100 hp.

When he withdrew from partnership in the firm of Clarke, Chapman, Parsons, and Company in 1889, Sir Charles released his patent rights. He then established his own turbine and dynamo works at Heaton-on-Tyne, and there continued for five years experiments toward producing a radial-flow turbine, although recognizing that his original invention, based on a parallel-flow system, was preferable. In 1892 he constructed a radial-flow turbine of 100-kw. output which consumed but 27 lb. of steam per kw-hr. In 1894 he purchased his original patent rights, and from then on advance was rapid.

By 1895 steam-turbine developments had attracted considerable interest in the United States, and a license agreement for building Parsons steam turbines for land purposes was entered into by the Westinghouse Company. About this time the principal shipbuilders also secured a license for turbines applicable to marine propulsion. In 1905 the Allis-Chalmers Company also secured a license. These licenses have been renewed from time to time, and the companies have continued to enjoy the advantages of technical information from Sir Charles's organization.

In 1913 Sir Charles furnished a 25,000-kw. tandem-compound turbine generator and condenser for the Fisk Street Station of the Commonwealth Edison Company, concerning the efficiency of which unprecedented guarantees were made. This turbine set a new standard of performance in this country. In the estimation of the purchaser, this machine has a standard of reliability to be compared favorably with any other on this system. In 1924 a second turbine was furnished the Commonwealth Edison Company, of 50,000-kw. capacity, of unique design in the low-pressure range of expansion. The object of this was to secure low leaving loss. The machine has operated excellently. Both of these turbine units were the largest of their time.

In 1894 Sir Charles devoted particular attention to the application of the turbine to the propulsion of ships. Owing to the necessarily high speed of rotation, difficult problems connected with propeller efficiencies were at once encountered, and it was not until after three years of experimental investigation that the famous *Turbinia* was completed. The speed performance of the *Turbinia* at the Victorian Diamond Jubilee Naval Review in 1897 attracted great attention to the system, and so rapid was the conversion of technical and public opinion in favor of the turbine for marine propulsion that by 1917 Atlantic liners with turbines of 80,000 hp. were in use in the merchant service.

Concurrently with improvement in the land turbines, corresponding advances in the marine turbine were made, so that today the coal consumption has been reduced to less than 1 lb. per shaft hp. per hour. The turbine is now universally adopted for the propulsion of warships and all high-speed vessels in the merchant service use the same prime mover. A development invaluable to oceanic transport service was Parsons' introduction of the helical gear for reducing the relative speed of the turbine to that of the propeller, so that the turbine could run at the maximum rated speed required for high thermodynamic efficiency, while the propeller revolved at the low speed conducive to propulsive efficiency. This latter invention is almost as great in its commercial results as the invention of the turbine itself.

Sir Charles did not restrict his exceptional knowledge and insight to the solution of problems of immediate utilitarian value. He studied the behavior of different bodies, particularly carbon under high pressure, and succeeded in converting this substance into graphite. Another important investigation which he carried out in conjunction with S. S. Cook, was the determination of the cause of erosion of high-speed screw propellers. This showed that a very important part in this phenomenon was played by water hammer. The main research on this subject was dealt with in a paper read before the Institution of Naval Architects in 1929.

Sir Charles showed a great interest in optics in later years. He took over the Derby Crown Glass Works and interested himself in constructing searchlights and their mirrors, and in solving other problems in connection with light. Later with Sir Howard Grubb he formed a company to make astronomical instruments and telescopes.

Perhaps his most important contribution to engineering development was to show that by employing higher steam pressures and temperatures in marine work it was possible to obtain higher efficiencies and a proportional economy in coal consumption. This demonstration was made in 1926 and took the form of equipping the Clyde pleasure steamer, *King George V*, with boilers supplying steam at a pressure of 550 lb. per sq. in. and a temperature of 800 deg. fahr. to a 3500-hp. turbine. The experiment was in the main successful, and the correctness of the ideas has been proved by the results obtained on the most recent vessels of the Canadian Pacific Company.

Sir Charles never lost his interest in steam turbines, and reviewed the progress that has been made recently in their design in two important papers which he read before the British Association in 1929 and at the World Power Conference in Berlin in 1930. In these he pointed out that in addition to an increase in the steam pressure and temperature, higher economy was to be sought in the use of regenerative heating, both of the feedwater and of the steam after partial expansion. He added that these developments, accompanied by the demand for larger and larger units, emphasized the value of a more economical utilization of materials used and led to the increasing employment of higher quality steel, multiple exhausts, and important modifications in the design of the condensing equipment. These changes are reflected in the design of more recent units for which Sir Charles was responsible, one of the most noticeable of which is the 40,000-kw. set installed in the Brimsdown station of the North Metropolitan Electric Power Company.

Sir Charles was a frequent contributor to the proceedings of the leading engineering societies, by which his preeminence as a scientist and pioneer was fittingly recognized in the course of his long connection with them. He was elected a Fellow of the Royal

Society as long ago as 1898, and was awarded the Rumford Medal in 1902 and the Copley Medal in 1928, being the first engineer to attain this high distinction. He became a member of the Institution of Civil Engineers in 1892, and served on its Council and that of the Institution of Mechanical Engineers. He was made an honorary member of The American Society of Mechanical Engineers in 1920, and of the Institution of Mechanical Engineers in 1925. He joined the Institution of Electrical Engineers in 1888, and was elected an honorary member in 1909, being awarded both the Franklin and the Faraday Medals of that Society. The three British institutions conferred the Kelvin Medal upon him in 1926. A further technical honor was the Bessemer Medal of the Iron and Steel Institute, which was awarded him in 1929. He was an honorary member of the Société des Ingénieurs Civils de France, and a member of the Verein deutscher Ingenieure. He was vice-president of the Institution of Naval Architects and president in 1913 and 1914 of the North East Coast Institution of Engineers and Shipbuilders. In 1904 he was president of Section G (Engineering) of the British Association, and in 1917 became president of the whole body. He also served as president of the Institute of Physics, the Institute of Marine Engineers, the Tyneside Unionist Association, and the Literary and Philosophical Society.

The Liverpool University conferred the degree of Doctor of Science on Sir Charles in 1909. He was also awarded similar honors by the Universities of Glasgow, Durham, Toronto, and Pennsylvania. He was made a C.B in 1904, a K.C.B. in 1911, and became a member of the Order of Merit in 1927.

During the World War he served on a number of committees, and was an original member of the Advisory Council of the Department of Scientific and Industrial Research and of the Fuel Research Board. Sir Charles threw himself with characteristic wholeheartedness into this work; he was tireless in suggesting new methods, in giving opportunities for experiments on a large scale, and in helping by his advice and criticism those who were carrying out investigations for the Board. He was a very agreeable as well as most efficient colleague, and through the questions before the Committee were such as to give room for wide differences of opinion, there was no friction and the proceedings were harmonious. In 1883 he married Katherine Bethell, who is a founder of the Women's Engineering Society. Their only son was killed in action in 1918. Their only daughter passed through the Engineering School at Cambridge, and served in the Training Department of the Ministry of Munitions.

Sir Charles was a generous benefactor of science, having given large amounts to the Royal Institution and to the British Association. He was one of the governors of the Dominion Students' Hall Trust, the object of which is the building of a hall of residence, London House, for Dominion, Colonial, and British students who come to the University and schools of London. In addition to a generous contribution, he gave much time to interesting the engineering profession in the scheme.

At the time of his death Sir Charles and Lady Parsons were on a pleasure trip on board the steamer *Duchess of Richmond*. After an illness of four days he died shortly before the vessel reached Kingston, Jamaica. His body was taken back to England on the first available boat. A memorial service was held in Westminster Abbey on March 3, attended by relatives, friends, and representatives of scientific and engineering societies. The American Society of Mechanical Engineers was represented. A memorial service was also held at St. Nicholas Cathedral, New-Castle on-Tyne, the same day, and interment was at Kirkwhelpington Churchyard.—C.W.S.

WORTHINGTON ELMORE PLATT

Worthington Elmore Platt, who died at Norwich, Conn., on August 7, 1931, was born in New Haven on April 15, 1903, the son of Elmore Wooster and Helena (Lowe) Platt. His early education was secured in the schools of New Haven, and he was graduated from Lehigh University, Bethlehem, Pa., in 1926, with a mechanical engineering degree.

For the next four years Mr. Platt was cadet engineer with the Consolidated Gas Company of New York, serving in each branch of the company. Since then he had been employed as superintendent of the Customer's Service Department of the East River Gas Company, Long Island City, N.Y. He perfected a cam used by that company.

Mr. Platt belonged to the Gas Engineering Society of New York and had been a junior member of the A.S.M.E. since 1926. He also belonged to the Masonic fraternity and was interested in boys' clubs and had served as camp councilor for the Y.M.C.A. Surviving him are his widow, Lois Stone (Caswell) Platt, whom he married in 1928, and one son, Charles Elmore Platt.

PAUL ALBERT POPPENHUSEN

Paul Albert Poppenhusen, who died on May 24, 1930, was born at College Point, L.I., N.Y., on November 4, 1873. His parents were Herman C. and Caroline S. (Funke) Poppenhusen. He received instruction from a private tutor until he was ten years old, when he was sent to boarding school at Kiel, Germany. After returning to this country he spent a year at Northwestern University, Evanston, Ill.

His first position was in the wholesale drygoods business and subsequently he was connected with the Bismarck Hotel Company of Chicago. In 1897 he organized the Green Engineering Company, East Chicago, Ind. for manufacturing Green chain-grate stokers, ash-handling equipment, and cast-iron storage tanks. He served as president of the company from 1906 to 1924. Since 1926 he had been a member of the firm of Acers-Poppenhusen, Chicago, Ill., dealing in power-plant equipment.

Mr. Poppenhusen belonged to the Western Society of Engineers, the Masonic fraternity, and a number of clubs in New York and Chicago. He became a member of the A.S.M.E. in 1912. He was interested in big game hunting and belonged to the Caughuawana Fish and Game Club of Quebec. He is survived by his widow, Helen Burk (Durham) Poppenhusen.

EDWARD BORIS POULSEN

Edward Boris Poulsen, whose death occurred on March 9, 1931, following an operation for appendicitis, was born in Oberpalen, Russia, on May 12, 1900. His technical education was secured at the Montana State College of Agriculture and Mechanic Arts, Bozeman, Mont., which conferred upon him the degree of B.S. in M.E. in 1923.

Following his graduation Mr. Poulsen accepted a position as draftsman for the Wheeling Steel Corporation at its Steubenville plant, Steubenville, Ohio. After two years there he went to Gary, Ind., as draftsman for the Gary Tube Company. In 1928 he became draftsman for the Michigan Copper & Brass Co., now known as the Michigan Division of the Revere Copper & Brass Co., at Detroit. He remained with this company until his death.

Mr. Poulsen became a junior member of the A.S.M.E. in 1924. He was a member of the Masonic fraternity and a Lutheran by faith. He had been a member of the Reserve Officers Training Corps at Montana State College.

Mr. Poulsen is survived by his widow, Katherine (Camp) Poulsen, whom he married in 1930.

FREDERICK RANDOLPH PRATT

Frederick Randolph Pratt, chief engineer in the Steam and Electric Department of the Hollingsworth & Vose Co., East Walpole, Mass., died on April 3, 1931. He was a native of Boston, where he was born on December 25, 1876. After completing high school he was employed as a machinist by the textile industry in New England until 1908. Among the companies by which he was engaged were the Crompton Company, Gregorys Woolen Company, E. H. Smith and C. L. Blanding mills in Rhode Island, Warrenton Woolen Company and Old Mystic Woolen Company in Connecticut, and Grant Yarn Company, in Fitchburg, Mass. He became master mechanic for the last-named company. From 1904 to 1908 Mr. Pratt also did some turbine assembly and road work for the General Electric Company, in West Lynn, Mass.

In 1908 Mr. Pratt accepted a position as master mechanic and chief engineer for the Shetucket Company, Norwich, Conn. The following year he went to Adams, Mass., to work in the same capacity for the Berkshire Manufacturing Company, with which he was connected until 1917. He was in East Walpole in 1917 as mechanical engineer for Bird & Son, in Pawtucket in 1918 and 1919 as mechanical superintendent for D. Goff & Sons, and in Providence in 1920 with B.B. & R. Knight. He next went to Shanghai, China, for the Whiting Machine Works. After returning to this country he became chief engineer for the St. Croix Paper Company, Woodland, Maine, where he remained until 1930. He had been with the Hollingsworth & Vose Co. since May 12, 1930.

Mr. Pratt became a member of the A.S.M.E. in 1914.

CHARLES JOHN PRENDERGAST

Charles John Prendergast, manager of the St. Louis office of the Bailey Meter Company, died on November 21, 1931, from injuries sustained the preceding day in a building collapse at Paoli, Ind.

Mr. Prendergast was born at North East, Pa., on May 14, 1903. He attended the high school there and was graduated from the

Case School of Applied Science in 1925 with a B.S. degree in mechanical engineering. During his summer vacations, while in college, he secured practical experience with several companies, among them the Bailey Meter Company of Cleveland. Following his graduation, he returned to the employ of this company as Cadet Engineer, Senior Division. Before being sent to the St. Louis office in 1930, he had served as sales representative in the Boston and Springfield, Mass., territories.

Mr. Prendergast became a junior member of the A.S.M.E. in 1925. He is survived by his widow, Thelma E. (Luce) Prendergast, whom he married in 1928, and by his mother, Mrs. Florence Prendergast.

ROBERT WESTALL PRYOR, JR.

Robert Westall Pryor, Jr., a member of the firm of Koithan and Pryor, New York, N.Y., died on June 10, 1931, at his home in Newark, N.J., after a six months' illness.

Mr. Pryor was born in Newark on July 31, 1881, and attended the public schools there. He received an M.E. degree from the Stevens Institute of Technology in 1902. He immediately took a position as sales engineer with the Buffalo Forge Company of Buffalo, N.Y., and after a period of intensive training was assigned to the branch office in New York. He engaged in many phases of paper mill work and in heating, ventilating, drying, and kindred lines, and was in charge of installation in many parts of the United States and Canada. His work involved a considerable amount of designing to effect the adaptation of equipment to existing plants.

In 1909 he joined in forming the partnership of Koithan and Pryor, sales engineers and representatives in charge of the New York Branch of the Buffalo Forge Company, the Carrier Air Conditioning Company, and the Buffalo Pump Company.

He became a junior member of the A.S.M.E. in 1907 and a member in 1913. He also belonged to American Society of Heating and Ventilating Engineers and to several clubs.

He is survived by his widow, Lillie (Keepers) Pryor, and by one daughter.

WILLIAM WOOD RICKER

William Wood Ricker, who died on January 27, 1931, was born at Portsmouth, Ohio, on August 22, 1873. His parents were James Wood and Louisiana (Moore) Ricker. At the age of seventeen he became an apprentice in the machine shop of the Portsmouth Foundry & Machine Works, where he remained until he entered Cornell University in 1892. He secured further experience there and with the Burgess Iron & Steel Co. during his college vacations, and following the receipt of his M.E. degree in 1896 went into the machine shop of the Brown Hoisting Machine Company, at Cleveland, Ohio. During 1898 he was a draftsman for this company and in 1899 helped to build a cantilever crane at Wm. Cramp & Sons, Philadelphia, and had charge of the construction of a coal handling plant at the New London Navy Yard.

After the completion of this work Mr. Ricker went to Honolulu, where he remained for about three years, engaging in the importation of plantation and railway supplies and the design and installation of special machinery and cranes. He then returned to the employ of the Brown Hoisting Machine Company as salesman and during his two-year connection in this capacity made two trips to Cuba for the company.

In 1904 the Niles Tool Works, Hamilton, Ohio, engaged Mr. Ricker as superintendent, and early in the following year, he was appointed a salesman for the Niles-Bement-Pond Company, with headquarters in New York, N.Y. In 1908 he became secretary and treasurer of the Guarantee Construction Company, New York, and retained the office of treasurer until his retirement at the close of 1929.

When the United States entered the World War Mr. Ricker was commissioned a major in the Ordnance Department and was stationed at Washington for some months. He was then sent to France, and subsequently promoted to the rank of lieutenant-colonel and served in France, Italy, and England, also being sent on a mission to Denmark.

Mr. Ricker became a member of the A.S.M.E. in 1906. He was also a member of the University, Cornell, and the Engineers' Clubs in New York, the Apawamis Club of Rye, N.Y., and several other clubs in Havana, Cleveland, and Washington, including the Army and Navy Club in Washington. He is survived by his widow, Abby Putnam (Morrison) Ricker, whom he married in 1925.

WINFIELD SCOTT ROGERS

Winfield Scott Rogers, pioneer of the ball bearing industry, died on February 17, 1931, at his home in South Orange, N.J., where he had lived since his retirement from business in 1929.

Mr. Rogers was born at Waynesburg, Pa., on July 21, 1853. While still attending public school he had his first experience in the operation of engines as a night employee of the Union Stock Yards at Columbus, Ohio, and subsequently he served a three-year apprenticeship as a machinist and draftsman with the C., H.V. & T. R.R. With this training he secured a position on the Columbus and Chicago Division of the P.C. & St. L. R.R. and was with this road and the Chicago Division of the Baltimore & Ohio R.R. for a number of years, working as fireman, brakeman, conductor, and engineer. He then withdrew from railroad service, accepting a position as diemaker and foreman of the sewing machine room of the Longstreth & Ayer Mfg. Co., Columbus. After a year with this company he spent about two years as superintendent of the Columbus Basket Company, three as draftsman, salesman, and general mechanical engineer for P.G. March & Co., Cincinnati, builders of machine tools, and some months as draftsman for the Black & Clawson Co., paper mill machinery manufacturers of Hamilton, Ohio.

At the time Mr. Rogers became a member of the A.S.M.E. in 1888 he was draftsman and assistant to the general manager of the Universal Radial Drill Company, and senior member of the firm of Jones and Rogers, in Cincinnati. The following year he was appointed mechanical engineer at the Watervliet (New York) Arsenal. In 1890 and 1891 he was superintendent of the estate of F. W. Richardson in Troy, N.Y., and then he was employed until the latter part of 1892 as superintendent and mechanical engineer for H. G. Hammett, of Troy. Subsequent to a year of general mechanical engineering practice he became engineer and airbrake instructor for the Delaware & Hudson Canal Co., at Green Island, N.Y. In 1895 he had an office in Buffalo and in 1896 in Philadelphia. During the next few years he was engaged in the manufacture of laundry machinery, first as superintendent of the American Laundry Machinery Company, Cincinnati, and in 1898 as a member of the firm of Rogers & Co., New York.

Mr. Rogers entered the ball bearing field in 1898 as an associate of Henry M. Whitney in The Ball Bearing Company, Boston. He was treasurer and general manager of the company until 1901. During the latter part of that year he served as vice-president and general manager of The Steamobile Company of America, Keene, N.H., and in 1902 was also connected with the Roller Bearing Equipment Company of that place. He then went to Bantam, Conn., as general manager of The Bantam Manufacturing Company. In 1903 he was appointed receiver for the company which he reorganized in 1905 as the Bantam Anti-Friction Company. He remained president and active head of the company until its reorganization in 1921 under the name of The Bantam Ball Bearing Company, of whose Board of Directors he was made chairman. The company relocated in South Bend, Ind., in 1928.

It was largely the result of the early pioneering efforts of Mr. Rogers that the value of anti-friction ball bearings became recognized in the mechanical world. His was the first commercial catalog of ball bearings published in this country. Among others of his works were the following: "Primer of the Air Brake," "Time and Cost Keeping," "Sketches of an Apprenticeship," "The Romance of Anti-Friction," a history of the ball bearing industry, completed shortly before his death, and "Oil Heating the Home," giving the results of five years of tests with various burners.

During his residence in Connecticut Mr. Rogers served two terms in the state legislature and was active in all movements for the benefit of his community. He was a former member of the Society of Automotive Engineers. Surviving him are his widow, Nellie S. Rogers, and two daughters.

JOHN L. ROSS

John L. Ross died on April 23, 1930, at his home in Roselle Park, N.J., of heart trouble. Mr. Ross was born in Detroit, Mich., on April 17, 1878, the son of Edward Holland and Susanna (Roche) Ross. He spent two years at Detroit College and then served an apprenticeship from 1897 to 1903 with the Detroit United Railroad, learning the machinist's, patternmaking, and electrical trades. In 1903 he established the Ross & Young Machine Co. in Detroit for the manufacture of automobile and marine internal-combustion engines. In its early years the firm built the Walker two-cylinder opposed motor, a line of four- and six-cylinder overhead valve and cam auto type marine motors, and the Demot two-cylinder opposed motors, transmissions, rear axles, and complete cars. Later a pattern shop and foundry were built, making it possible to produce the necessary castings, and the company manufactured four-cylinder motors, transmissions, and complete Paige "25" cars for the Paige-Detroit Motor Car Company. In 1915 the Ross Automobile Company was organized to build an eight-cylinder V-type motor and car known as the "Ross Eight." This plant was sold in 1917.

Mr. Ross then accepted a position with the Wright-Martin Aircraft Corporation at New Brunswick, N.J. He was the representative of the factory manager to outside manufacturers for the Wright-Martin Aircraft Corporation, having full charge of blueprints and specifications, tools, and materials for them. For a time after the War Mr. Ross was located in the mechanical department of the Kelly Press Division of the American Type Founders Company, Elmora, N.J. He established his own business as a consulting engineer in New York in 1925.

Mr. Ross had been a member of the A.S.M.E. since 1912. He is survived by his widow, Ruth (Porter) Ross, whom he married in 1917.

CHARLES M. ROSWELL

Charles M. Roswell, mechanic power and electrical engineer for the Western Electric Company, New York, N.Y., was born at Sparta, Ky., on December 3, 1884, the son of William Thomas and Mary E. (Rice) Roswell. He received a B.M.E. degree from the University of Kentucky, Lexington, Ky., in 1908 and an E.E. degree from the same institution three years later. The electrical work which led to the latter degree was done with the Jackson Elec. & Hydraulic Mfg. Co., at Jackson, Ky., where he was located in 1908 and 1909, and with the General Electric Company at Schenectady, N.Y., where he completed the regular student test course.

Mr. Roswell remained with the General Electric until 1918. He tested large vertical and horizontal turbines and worked on design in the direct current and central station departments, serving for four years as assistant head of the latter. In 1918 he went to Bluefield, W. Va., to supervise the operation of two water power plants and three steam plants, totaling 40,000 kw., for the Appalachian Power Company. Later he had charge of the design and construction of a new substation and made a layout for a new relay system covering the entire operation of the plant. From Bluefield he went to Charleston, S.C., in 1920, as superintendent of the electrical department of the Charleston Consolidated Railway & Lighting Co. He was in charge of a 10,000-kw. steam power plant and the distribution and street lighting system and designed transformer stations and line extensions.

Since 1921 Mr. Roswell had been connected for short periods each with a number of companies. He designed and estimated the cost of electrical stations and substations for the subsidiary properties of the United Gas Improvement Company, Philadelphia, Pa., supervised the testing and inspection of a new 20,000-kw. steam power plant at Hunlock Creek, Pa., for the Luzerne County Gas & Elec. Co., and made steam heating surveys in Philadelphia for Day & Zimmermann, Inc. He engaged for a time in sales engineering, buying and selling turbines, boilers, transformers, motors, and engineering supplies, and also did sales work for the McClave-Brooks Company, selling grates and stokers in the Philadelphia and Scranton territories, and for the D. B. Wilson Co., of Philadelphia, selling refractories and powdered fuel equipment. For about a year he was connected with Louis T. Klauder, consulting engineer of Philadelphia, for whom he checked the electrical drawings for the new Princeton University chemical laboratory and made surveys and wrote specifications for other construction jobs. He made inspections of machinery and did survey and appraisal work for the Scofield Engineering Company, Philadelphia, the largest assignment of which was the appraisal of the John Lang Paper Company, in that city. Prior to his connection with the Western Electric Company he was located at Scranton, Pa., as mechanical engineer for the new Masonic Temple and Scottish Rite Cathedral built by the Central Construction Corporation, of Harrisburg, Pa.

Mr. Roswell died at the Fairmount Private Hospital in Jersey City, N.J., on July 2, 1931. He is survived by his mother, living in Carrollton, Ky., and by a son, Charles Alfred Roswell. His wife was Miss Emma Baker of Lexington, Ky. He had been a member of the A.S.M.E. since 1928 and belonged also to the American Institute of Electrical Engineers.

ETHELBERT A. RUSDEN

Ethelbert A. Rusden, president of The Textile-Finishing Machinery Company, Providence, R.I., died on February 16, 1931. Mr. Rusden, who was born in Bowden, Cheshire, England, on September 5, 1859, was prominent in the industry not only in this country, but in a number of foreign countries, where he spent some time before coming to the United States.

At the age of fifteen, Mr. Rusden entered the service of the firm of Mather and Platt, at the Salford (England) Iron Works. He was connected with this company for seventeen years, five of which he spent in Russia as engineer at the Schlusselberg Print Works. At the age of twenty-one he was commissioned to manage the firm's exhibit of machinery at the Paris Exposition, and for his services was awarded the gold medal of the company. He was also sent to China and Japan to supervise the construction and equipment of manufacturing plants and made connections in those countries which he maintained throughout the succeeding years.

In 1887 Mr. Rusden came to the United States and established the Rusden Machinery Company at Warren, R.I. This firm was later merged with others to form The Textile Finishing Machinery Company of Providence, manufacturers of bleaching, dyeing, and printing machinery. Mr. Rusden was its general manager until 1910, and had been president since then.

Mr. Rusden was for years a prominent figure in the business life of Rhode Island. He had a notable career in the textile industries of America and foreign countries. A mechanical engineer of high attainments, he was regarded as an authority in this industry throughout the world.

Mr. Rusden became a member of the A.S.M.E. in 1920. He also belonged to the Providence Engineering Society, the Ancient and Honorable Artillery Company of Boston, the Masonic fraternity, and a number of clubs, including the Engineers' Club of New York. A man of unusual culture and refinement, he was a patron of the arts, a great lover of music, and a world traveler.

Surviving Mr. Rusden are his widow, Margaret (Lawlor) Rusden, and Ethelbert A. Rusden, Jr., a son by his first wife, who died in 1918.

RUDOLPH W. RUSTERHOLZ

Rudolph W. Rusterholz, associated for more than twenty-five years with the Ingersoll-Rand Company, died in Johannesburg, South Africa, on June 12, 1931.

Mr. Rusterholz was born at Peoria, Ill., on September 18, 1877. He was the son of R. &. R. (Hoffman) Rusterholz. He was graduated from Purdue University, Lafayette, Ind., in 1906 with a degree of Bachelor of Science in Mechanical Engineering. He entered the employ of the Ingersoll-Rand Company as sales and mechanical engineer and, during 1907 and 1908, was in charge of irrigation work in the South. During the next two years, he designed and installed various municipal waterworks plants in the Middle West. He then went to South Bartonville, Ill., where he designed and installed a water system for the Illinois General Hospital for the Incurable Insane. In 1911 he also installed a system for the County Infirmary at Oak Forest, Ill. In 1911 and 1912 he was advisory engineer for a complete compressed air installation in the L. &. H. Ry. shops at South Louisville, Ky., and also designed and acted as advisory engineer in connection with the McCarron Lake Pumping Station for the St. Paul (Minneapolis) Waterworks. From 1913 to 1918, Mr. Rusterholz was manager for the Ingersoll-Rand Company at Butte, Mont. He had been located in Johannesburg since 1918 as chairman and managing director of the Ingersoll-Rand Company (S.A.) Ltd.

Mr. Rusterholz belonged to the U.S. Engineer Corps during the Cuban War and during the World War served as Captain in the U. S. Air Service in France. In 1919 he was attached to the American Peace Commission in Paris.

In addition to the A.S.M.E., of which he had been a member since 1913, Mr. Rusterholz belonged to the American Institute of Mining and Metallurgical Engineers, the South African Institute of Engineers, the Engineers Club of London, and a number of clubs in South Africa. He is survived by his widow, Nita M. (Kabat) Rusterholz, whom he married in Portland, Ore., in 1912.

CARL HUGO SATHERBERG

Carl Hugo Satherberg was born at Carlstrona, Sweden, on August 29, 1853. He attended the Technical School of Norrköping, Sweden, and the Polytechnic Institute of Stockholm. His early experience was secured in the drafting room of the Motala Iron Works, Sweden, and the shops of the Swedish government at Liljeholmen, Stockholm. He went to Manchester, England, in 1877 to work in the locomotive shops of Beyer and Peacock.

Mr. Satherberg came to the United States in 1880 and for seven years was employed as chief draftsman at the Midvale Steel Works in Philadelphia. During the next three years he was construction engineer for the Pennsylvania Steel Company, Steelton, Pa. He returned to the employ of the Midvale Steel Company in 1890 and remained with it as mechanical engineer and chief draftsman until he retired in 1917. His most important contribution to the industry was in the design of melting and heating furnaces, heavy hydraulic forging presses, car-wheel rolling mills, and other heavy steel-mill machinery.

Mr. Satherberg became a member of the A.S.M.E. in 1893. He also belonged to the Art Club of Philadelphia. His wife, Eliza-

beth T. (Brant) Satherberg, died in 1929. His own death occurred on July 19, 1931, at the University of Pennsylvania Hospital in Philadelphia.

WILLIAM LAWRENCE SAUNDERS

William Lawrence Saunders, chairman of the board of directors of the Ingersoll-Rand Company, New York, N.Y., died on June 25, 1931, at Teneriffe, Canary Islands, while on a tour of the world. His career as an engineer extended over more than half a century, with a record of distinguished public service in his later life. Perhaps the most important public position he occupied was that of chairman of the Naval Consulting Board, to which he was appointed in 1915. He applied himself to the study of submarine warfare and evolved the theory that an unsinkable boat could be had by filling the inner hull with a large number of wooden boxes, the buoyancy of which would keep the ship afloat no matter how riddled by torpedos she might be. Such a boat the *Lucia*, was fitted out and used for transporting troops to France, but Mr. Saunders' theory was never tested, as the ship was not struck.

Mr. Saunders was born at Columbus, Ga., on November 1, 1856, the son of William Trebell and Eliza (Morton) Saunders. He was graduated from the University of Pennsylvania in 1876 with the degree of Bachelor of Science and was given an Sc.D. degree by that institution in 1911. In 1925 he received the honor cup of the University, awarded annually to its most distinguished alumnus. He had served as president and member of the council of the University of Pennsylvania Club of New York.

For several years following his graduation Mr. Saunders engaged in newspaper work in Philadelphia, and in 1878 he began his engineering career with the National Storage Company of Communipaw, N.J., where he was in charge of hydrographic work and subaqueous rock excavation from 1878 to 1882, in connection with the building of docks, warehouses, and a ship channel at Black Tom Island, New York harbor. Later he was successively engineer, vice-president, and president of the Ingersoll-Sergeant Drill Company, and president of the Haesler Pneumatic Tool Company and the New York Imperial Tool Company. When the Ingersoll-Sergeant Drill Company was succeeded by the Ingersoll-Rand Company he became president and ultimately chairman of the board. He had also been a director of the A. S. Cameron Steam Pumps Works, American International Corporation, and New York & Honduras Rosario Mining Co., and president of the Stayley-Saunders Corporation.

Chief among the inventions by Mr. Saunders was the apparatus for drilling rock under water and the Ingersoll track and bar channelers and gadders for quarrying dimension stone, marble, and limestone. He also invented the radialaxe system for coal mining and the method of pumping liquids by compressed air. For some years he was the editor of *The Compressed Air Magazine*, and he edited "Compressed Air Data," a handbook issued by the publishers of that journal in 1924. He also edited "Compressed Air Information," a symposium of papers on the production, transmission, and use of compressed air, and was the author of "Compressed Air Production," as well as of many pamphlets and articles for the technical press. He was a co-author (with Gilbert and Wightman) of "Subways and Tunnels of New York" and (with Dana) of "Rock Drilling."

During the World War Mr. Saunders also served on the district committee on capital issues of the Federal Reserve Board, on the advisory board of the Fuel Administration, and on the Military Engineering Committee, which at its own expense equipped a regiment and sent it to France.

One of the most prominent members of the Democratic party in New Jersey, Mr. Saunders had been a member of the state's Democratic committee and in the presidential campaign in 1916 was one of New Jersey's representatives on the Democratic National Committee, as personal representative of Mr. Wilson. He was a delegate to the Democratic National Convention in 1924. He had twice been mayor of North Plainfield, N.J., and maintained a home in Plainfield as his voting residence. He had been a member of the New Jersey Harbor Commission and the New Jersey Board of Commerce and Navigation. He was a former governor, director, and deputy chairman of the Federal Reserve Bank of New York, a member of the special committee on workmen's compensation legislation of the New York Chamber of Commerce, a member of the Federal Trade Commission, chairman of the Permanent Group Committee for Nicaragua, and a member of the International Fixed Calendar League. He had been chairman of the industrial training committee of the National Civic Federation, a member of the committee on education of the National Foreign Trade Council, and a member of the United States Chamber of Commerce.

Mr. Saunders was greatly interested in discovering a cure for cancer. In 1926 he announced through the American Society for the Control of Cancer that he would present a prize of $50,000 for the discovery of a positive cure. After two years he was convinced of the futility of the search and withdrew his offer. He was honorary governor of the New York Skin and Cancer Hospital.

Mr. Saunders was very active in the work of engineering and scientific organizations, particularly that of the American Institute of Mining and Metallurgical Engineers, of which he was president in 1915. He represented the Institute at the First Empire Mining and Metallurgical Congress at the Wembly Exposition, London, in 1924. Two years later he founded the Mining Medal of the Institute, to recognize achievement in mining. He was also a member of the Mining and Metallurgical Society of America and the American Iron and Steel Institute.

Others of the four national societies to which he belonged were the American Society of Civil Engineers and the A.S.M.E., which he joined in 1928. He was a former president, trustee, and member of the finance committee of the United Engineering Society.

Mr. Saunders was a fellow of the American Geographical Society, past-president of the American Manufacturers' Export Association, honorary vice-president of the International Benjamin Franklin Society, and a member of the Academy of Political Science and the American Academy of Political and Social Science. Although a resident of the northern part of the United States for many years he kept in touch with the South, where he was born, through membership in the New York Southern Society. His club memberships included the Machinery, of which he was a past-president, and the India House, Engineers', and University Clubs in New York.

His wife, Bertha L. (Gaston) Saunders, whom he married in 1886, died in 1906, leaving him two daughters, Mrs. Maxwell Evarts Perkins and Mrs. John E. Lancaster, Jr.

THOMAS H. SAVERY, JR.

Thomas H. Savery, Jr., who died on December 31, 1930, as the result of a fall, was born at Wilmington, Del., on May 31, 1871, the son of Thomas H. and Sarah (Pim) Savery. He received an M.E. degree from Cornell University in 1896 and during the next five years he was employed in the manufacturing and sales departments of the Pusey & Jones Co., in his native city. His duties included the supervision of manufacture and installation of machinery for pulp and paper mills.

In 1901 he went to Denver, Colo., as manager and treasurer of the Rocky Mountain Paper Company. Mr. Savery had full charge of the purchase and erection of all machinery for the ground wood and sulphite plants as well as the paper mills. A special plant for handling and de-inking waste papers was designed and developed under his supervision.

From Denver, in 1912, he transferred to Sandusky, Ohio, where for four years he was connected with the manufacturing and sales departments of the Sandusky Foundry & Machine Co. He developed and patented several important features in connection with special suction rolls, including rubber covered suction press rolls, suction screen plate cleaners, and top felts for suction rolls to eliminate marking.

Since 1916 Mr. Savery had been in business for himself as manufacturer's agent, with headquarters in Chicago, selling pulp and paper mill machinery exclusively and representing several companies in this line, including the Nash Engineering Company, South Norwalk, Conn., and the Bird Machine Company, South Walpole, Mass. He served also as a consulting engineer, recommending special machinery to meet the varying conditions in pulp and paper mills.

Mr. Savery had been a member of the A.S.M.E. since 1917. He also held membership in the Technical Association of the Pulp and Paper Industry, and the Society of Cornell Engineers, as well as in several clubs.

Mr. Savery married Lida Moore, of Wilmington, in 1897, and is survived by her and by five children, Esther, Helen, Thomas H., 3d, Donald Fenwick, and Eleanor Irving.

WILLIAM SAXON

William Saxon, vice-president in charge of manufacturing for the Miehle Printing Press & Manufacturing Co., Chicago, Ill., died on October 5, 1931, at his residence in Oak Park, Ill. He had not been active in business for several years because of illness.

Mr. Saxon was born in Christiania, Norway, on July 6, 1857, the son of Christian and Alice (Tomilson) Saxon. Later he moved with his parents to Manchester, England, where he spent three years at the Mechanics Institute, being graduated in 1878. He also served an apprenticeship as a machinist with Parr, Curtis & Company of Manchester. He returned to Norway as machinist and draftsman for J. & A. Jensen & Dahl. He came to the United States in 1883 and

secured work as draftsman and machinist on steam engine work for William McGregor & Co., in Chicago.

Mr. Saxon had his first experience in the printing industry as shop foreman from 1887 to 1889 for a Chicago firm in printing press work. During the next two years, he was foreman for the S. K. White Company of Chicago, which at that time had undertaken the manufacture of the then practically unknown Miehle printing press. This company was taken over in 1891 by the Miehle Company, of which Mr. Saxon became general superintendent and later vice-president.

Mr. Saxon joined the A.S.M.E. in 1906. Surviving him are his widow, Marie (Jacobsen) Saxon, whom he married in 1881, and three children, Mrs. Alice Press, Mrs. Curtis Crafts, and William J. Saxon.

ALBERT JEFFERSON SAYERS

Albert Jefferson Sayers, associated with the Link-Belt Company since 1899, died at his home in Chicago, Ill., on October 11, 1931.

Mr. Sayers was head of the Coal Tipple and Coal Washery Department of the Link-Belt Company. He was well known throughout the entire coal industry, having designed and built numerous plants for the handling and preparation of coal, in all parts of the country, and was recognized as one of the leading designers of this type of equipment.

He was born on September 10, 1870, at Troy, Ohio, the son of Judson and Mary (Gearhart) Sayers. He was educated at the University of Illinois, from which he was graduated in 1895 with a B.S. degree in mechanical engineering.

Following his graduation, he was engineer in charge of the steam plant of the Illinois Central Railway at New Orleans, La., for a year, and spent two years as engineer in charge of the Physical Testing Laboratory of the Sargent Steel Company of Chicago. In the thirty-two years of his affiliation with the Link-Belt Company, Mr. Sayers became a leading factor in the mechanical handling, screening, and washing of coal.

He had been a member of the A.S.M.E. since 1913 and belonged to the Manufacturers Division of the American Mining Congress and to other engineering organizations, where his contributions to the advancement of engineering principles adaptable to the industry were recognized factors of importance.

Mr. Sayers is survived by his widow, Mabel J. (Penfield) Sayers, whom he married in 1901, and by two children, Edith E. and Robert P. Sayers.

FRANZ SCHULTZ-BALLUFF

Franz Schultz-Balluff, whose death occurred in Germany on August 5, 1931, was born at New York, N.Y., on December 15, 1887. He was educated in Germany, attending the Realgymnasium at Stuttgart for ten years and securing his engineering degree from the Technische Hochschule there in 1911. He entered the Diesel Department of the Motorenfabrik Deutz A.G., as draftsman, and remained with this company until his death, with the exception of four years during the World War which he spent in the Heavy Artillery.

Dr. Schultz-Balluff devoted a large part of his time to research work. He was made chief of the Research Department of the company in 1918, technical manager in 1920, and vice-president in 1923. He was also technical manager of the Motorenfabrik Oberursel A.G. from 1921 to 1927, reorganizing its plant near Frankfort on the Main. From 1925 to 1927 he was engaged as technical manager of the Maschinenbauanstalt Humboldt at Köln-Kalk, a firm dealing with the standardization of steam-turbines, ice-machines, and compressors.

Dr. Schultz-Balluff studied and designed a large number of Diesel engines, decreasing the number of types and making different types adaptable to all fuels and services. He had been a member of the A.S.M.E. since 1927 and also belonged to the Verein Deutscher Ingenieure.

Surviving Dr. Schultz-Balluff are his widow, Ida Schultz-Balluff, and three children, Michel, Volker, and Renate Schultz-Balluff.

SEATON MACKENZIE SCOTT

Seaton Mackenzie Scott, who died of heart failure on January 12, 1931, in Brooklyn, N.Y., was born on February 19, 1860, at Montreal, Canada, the son of Thomas Seaton and Mary (Mackenzie) Scott. He studied mechanical engineering at the Collegiate Institute, Ottawa, Canada, and served a three-year apprenticeship in the pattern shops and foundry of the Vulcan Iron Works there. He secured his drafting and shop experience in the office of the chief engineer of the Canadian Government Railway at Ottawa and at the Kingston Locomotive Works at Kingston, Ontario. He was employed by the Canadian Pacific Railway and Grand Trunk Railway as locomotive foreman, traveling inspector, and draftsman.

Mr. Scott left Canada in 1885, and later became a naturalized citizen of the United States. He was employed by the C. &. C. Motor Company, Chicago, the Brooklyn Distilling Company, and the Kelly & Jones Co., Greensburg, Pa., prior to 1898, when he began consulting work in New York. The Goldschmidt Thermit Company (now the Metal & Thermit Corp.) and Abendroth & Root Mfg. Co. were among the companies by which he was employed about 1900. Later he was engaged for a number of years in power plant work for the N.Y. Edison Co. and other Edison organizations. He helped to design and supervised the construction of several plants, including one in Philadelphia and the Waterside Station in New York, and also had charge of some construction work at the laboratories in West Orange.

Mr. Scott served as a Major in the United States Air Corps during the World War. He was connected with the Plant Appraisal Bureau, making appraisals of many ma'or aircraft plants, including the Wright-Martin Aircraft Corporation and the Aeronautical Engine Corporation. Upon completion of his war service, he re-entered commercial engineering as designing engineer for Ophulls & Hill, Inc., refrigeration engineers, of Brooklyn, a position which he held until shortly before his death.

Mr. Scott became an associate of the A.S.M.E. in 1896 and a member the following year. He is survived by his widow, Louise (Ludlum) Scott, and by two sons, Seaton M. Scott, Jr., and Maxwell J. Scott.

DWIGHT SEABURY

Dwight Seabury, a native of Providence, R.I., died in that city on April 21, 1931, following a brief illness.

Mr. Seabury was born on February 14, 1863, the son of Dr. Frederick and Amelia (Wheaton) Seabury. He attended the Providence High School and the Mowry & Goff (technical training) School in that city, and in 1881 began a three-year apprenticeship with Thompson & Nagle, Providence, in general mill construction. He then spent two years in the Providence mills of B.B. & R. Knight, following which he secured a position with the firm of F. P. Sheldon. After nine years with this company, during three of which he was in charge of the office, he went into business for himself, with an office in Pawtucket, R.I.

Throughout his life Mr. Seabury engaged in mill engineering and architecture. Among the Pawtucket mills designed and built under his supervision are the plants of the Royal Weaving Company, E. Jencks Manufacturing Co., A. T. Athetton Machine Co., Solvay Dyeing and Textile Co., and the Lumb Knitting Company. He designed the G. W. Parks Co., Waite-Thresher, N-Barstow Company, and Hanley buildings in Providence, the plant of the Portland Silk Company, Middletown, Conn., the Brighton Mills, Passaic, N.J., Pennekees Mills, Valley Falls, R.I., and Fort Dummer Mill, Brattleboro, Vt.

Mr. Seabury became a member of the A.S.M.E. in 1906. He also belonged to the New England Manufacturers' Association, the Southern New England Textile Club, and the Dixon-Spencer Associates, a social organization of prominent mill men. He is survived by his widow, Hattie I. Seabury.

BRUCE SETTLE

Bruce Settle, whose death occurred on December 29, 1930, was born at Gainesboro, Tenn., on February 7, 1898. He attended the United States Naval Academy and was appointed a Midshipman in June, 1917. Three years later he was commissioned a regular Ensign. He served for a time as First Assistant Engineer on the U.S.S. *Raleigh* and, at the time of his death, was stationed at the United States Navy Yard at Washington, D.C.

Lieutenant Settle received an M.S. degree from Columbia University in 1927. He became a junior member of the A.S.M.E. in 1928.

WILLIAM H. SHELMIRE, JR.

William H. Shelmire, Jr., died in his native city of Philadelphia, Pa., on July 31, 1931. He was born there on October 1, 1855, the son of William H. and Sarah Ann Shelmire. After completing his high-school education, he was apprenticed to A. L. Archambault, builder of marine and stationary engines. The business failed before Mr. Shelmire had compled his apprenticeship and he spent a short time in the engine room of the steamer *Juniata*, shipping to Cuba and New Orleans. Later, he completed his apprenticeship with G. C. Howard of Philadelphia. He also availed himself of the lectures and library of The Franklin Institute.

Upon the completion of his apprenticeship. Mr. Shelmire went to Terre Haute, Ind., where he spent three years in the employ of the

Vandalia Railroad Company as gang foreman in the erecting shop, draftsman, and mechanical engineer. He then returned to Philadelphia to work, first as draftsman, and later as assistant to the superintendent at the Pencoyd Iron Works of A. & P. Roberts & Company.

At the time Mr. Shelmire became a member of the A.S.M.E. in 1889 he was assistant superintendent of the Diamond State Iron Company at Wilmington, Del. Shortly afterward, he was engaged by the Kensington Engine Works, Ltd., of Philadelphia, where he remained for about two years. From 1903 to 1905 he was general superintendent of the Creswell & Waters Company, Nicetown, Pa., in 1906 mechanical engineer for the Cambria Steel Company, Johnstown, Pa., and from 1907 to 1913 mechanical and supervising engineer for the John Lang Paper Company of Philadelphia. In the intervening periods, and from 1913 until his death, he engaged in consulting work. The firm of Charles W. Shelmire, Inc., of which he was vice-president for the first year and subsequently president, was established in 1926.

Mr. Shelmire was a member of the Masonic fraternity and of the Society of Friends. He is survived by his widow, Lucy (Cope) Shelmire, whom he married in 1882.

VISCOUNT EI-ICHI SHIBUSAWA

Japan's "grand old man," Viscount Ei-ichi Shibusawa, died on November 11, 1931, He was 91 years old. One of America's earliest and most steadfast friends in Japan, he was called the "people's foreign minister" because of the trips he made to the United States, particularly when Japan's immigration question was under discussion. For years he was the nation's leading banker, merchant, industrialist, mine owner, and one of the founders of Japan's modern business system. His power at home was exceeded only by that of the royal family.

Viscount Shibusawa's friendship for the United States was apparent as early as 1861 when, at a time when the intentions of foreigners were seriously misunderstood in Japan, he stood guard with others night and day before the residence of Townsend Harris, the first Consul-General of America in Japan.

Those were turbulent days in Japan, for among its people were many who bitterly censured the Shogunate for alleged blunders in the conduct of diplomatic affairs and who nursed intense hatred toward foreigners, and frequently resorted to violence. In January, 1861, Henry C. J. Heuskin, Mr. Harris' valued associate, was assassinated by rowdies. All the foreign ministers then in Japan, with the exception of Mr. Harris, blamed the Shogunate for its incompetency to protect them, and closed their legations and withdrew. Mr. Harris did not approve of this step and remained to attend to his duties. It was then that the guard was placed before his residence. Commenting on this action later Viscount Shibusawa wrote: "The courageous and magnanimous attitude taken by Mr. Harris on this critical occasion made a strong appeal to the imagination of our people, who were now convinced of the genuineness of his sentiment toward them, and who from that moment began to put trust in America as a true friend of Japan."

His regard for the United States is revealed by the fact that he headed many of the Empire's delegations to American shores in the interests of friendship and economic exchange between the two nations. He was president of the American Relations Committee of Japan, and later became chairman of the American-Japan Society of Tokyo, similar to the organizations in the United States.

Viscount Shibusawa was made an honorary member of The American Society of Mechanical Engineers in 1929 during the visit of American engineers to the World Engineering Congress at Tokyo. This was in recognition of the important part he played in the industrial and economic development of the Japanese nation, his efforts toward the promotion of world understanding, and his support of and interest in physical and chemical laboratories and in all branches of engineering in Japan.

Even after he had reached an advanced age Viscount Shibusawa continued his world travels, the last of his several visits to the United States being made in 1921 at the age of 81. Even then, though he had retired from many of his business connections, he was most active, rising at six or seven in the morning and working from 12 to 15 hours a day. During his life he was president of more than 70 corporations, for nearly three-quarters of a century was a trusted adviser of successive Japanese governments.

Viscount Shibusawa was born on February 13, 1840, the son of an indigo merchant, in a small village near Edo, the present city of Tokyo. In his boyhood he received a thorough education in the Chinese classics and learned the art of the sword from the masterful Chiba. Going to Kyoto, then the capital, he entered the service of Lord Hitotsubashi, member of an influential branch of the Shogunate Tokugawa family. In 1867, a year before the downfall of the Shogunate, he was sent to France with Lord Bimbu, a brother of the reigning Shogun. When the imperial government was established in 1869 he was made a vice-minister in the Finance Department. Three years later he left the government service and began his great business career. One of his first acts was to establish the First National Bank, the pioneer national bank in Japan. He helped to found the Tokyo Chamber of Commerce, the Tokyo Bankers' Association, the Bankers' Clearing House, the Tokyo Stock Exchange, the Tokyo Marine Insurance Company, the great maritime firm Nippon Yusen Kaisha, and scores of other businesses of world-wide influence.

He was a leading figure in the organization of the Japan Mail Line and the expansion of the nation's maritime efforts. The development of the cotton spinning industry in Japan is largely due to his initiative, as well as other manufacturing enterprises such as silk weaving, hemp and rope mills, concrete plants, sugar refining, and affiliated projects of this modern age. In cooperation with government authorities he acted to improve Japan's natural production and resources by reclamation work and harbor construction, by improving agriculture to increase returns, and through the medium of introducing artificial fertilizers and high grade cattle and stock breeding.

Early in the Meiji era, feeling that Japan's younger generation needed more facilities for commercial education, Viscount Shibusawa established a training school which became the forerunner of the present Tokyo Higher Commercial College. In charity movements his name always led all the rest. He was a leader in the establishment of the Tokyo Poor House and other charitable organizations. His promotion to the peerage in 1900 was in consideration of the immense service he rendered to the country's commercial and industrial development as well as to the cause of public welfare.

As Baron Shibusawa, he made his first trip to this country in 1902 to study commercial and industrial progress. In 1909 he visited the United States as the head of an official Japanese business delegation invited to come here by the Chamber of Commerce of the United States. In 1915 Baron Shibusawa returned to the United States to visit the San Francisco exposition and discuss certain commercial and political questions.

One day of each month Viscount Shibusawa devoted to religious matters, having read to him passages from Confucius. He was one of the greatest authorities in Japan on Chinese classics, and was an ardent follower of Confucian precepts. It is probable that the fortune he had left is the largest ever accumulated by any individual business man in Japan.—C.W.S.

EDWARD ALFRED SIMMONS

Edward Alfred Simmons, president of the Simmons-Boardman Publishing Corporation, New York, N.Y., died of cerebral hemorrhage at his home in Brooklyn on September 30, 1931. He was born in Brooklyn on March 20, 1875, the son of John Wesley and Agnes Anne (Owers) Simmons. He was educated in the public schools there. He entered the employ of the *Railroad Gazette*, a predecessor of the present *Railway Age*, at the age of 14 and was continuously associated with this publication until his death. In 1911 Colonel Simmons effected the merger of the *Railroad Gazette* and the *Railway Age* (Chicago), which were thereafter published as the *Railway Age-Gazette*, later simplified to *Railway Age*, becoming president of the Simmons-Boardman Publishing Company which was organized to take over the properties. The *Railway Review* was merged with the *Railway Age* in 1926.

In 1928 the Simmons-Boardman Publishing Corporation was formed under the presidency of Colonel Simmons. It acquired control of the Simmons-Boardman Publishing Company, publisher of the *Railway Age*, *Railway Mechanical Engineer*, *Railway Engineering and Maintenance*, *Railway Electrical Engineer*, *Railway Signaling*, *The Boiler Maker*, and *Marine Engineering and Shipping Age*, and also of the American Builder Publishing Corporation, publisher of the *American Builder*, with which several other building periodicals have since been combined under Colonel Simmons' leadership.

Colonel Simmons was chairman of the board of directors of the American Saw Mill Machinery Company, which he organized in 1904; president of the American Saw works, organized in 1907; and chairman of the board of the American Machine Tool Company, organized in 1915, Rogers-Eagle Grinding Machine Company, organized in 1926, and the Corley Manufacturing Company and Eagle Saw Company, purchased in 1926 and 1927, respectively, by the American Saw Mill Machinery Company.

Colonel Simmons was regarded as an authority on water and rail transportation problems. As chairman of the American Marine Standards Committee he was an outspoken advocate of the development of a great merchant marine in the United States. He was chairman of the United States delegation to the International Railway Congress in London in 1925 and to the Madrid Congress in 1930.

For his work as a major in the Construction Division of the Army

during the World War, Colonel Simmons was praised highly in a citation signed in 1919 by Brigadier-General R. C. Marshall, Jr. The citation read: "A spirit of loyalty and competent effort has characterized your service in the Construction Division and was particularly helpful in the successful prosecution of the largest war construction program ever undertaken." Colonel Simmons supervised army construction work in and around New York, and during 1918 was in charge of twenty-two separate projects. These included the $2,500,000 Government hospital at Fox Hills, Staten Island. When the War closed he was under orders to go to France.

After leaving the army he was commissioned lieutenant-colonel in the Reserve Corps in 1919. Three years later he became a colonel. He was active in 1919 in organizing several posts of the American Legion. He was made commander of the Kings County (N.Y.) Post No. 500 and was a representative of the Legion at the funeral services for the first soldiers brought from France to the United States for reburial. Later he took charge of many similar services in Brooklyn and Hoboken, N.J. He was commander of the Legion in Kings County in 1923 and became president of the Department of New York of the Reserve Officers Association of the United States in 1930. He had also served two terms as president of the Brooklyn Chapter of the Reserve Officers Association and was a member of the Society of American Military Engineers, Military Order of the World War, New York Society of Military and Naval Officers of the World War, and the Quartermasters Association.

Colonel Simmons became an associate of the A.S.M.E. in 1919. He also belonged to the American Society of Civil Engineers and the Society of Naval Architects and Marine Engineers. He was chairman of the Endowment Committee of Engineering Foundation, Inc.

Colonel Simmons was re-elected honorary president of the New York State Division of the Izaak Walton League of America in September, 1931. His clubs included the Engineers', Bankers, Railroad, Union League, Automobile, and Army and Navy, of New York; Engineers' Country of Roslyn, L.I.; Congressional Country, and Army and Navy of Washington, D.C.; Adirondack League Club of Old Forge, N.Y.; Thendara Golf Club, Thendara, N.Y.; Inlet Golf Club, Inlet, N.Y.; Lake Placid; and Sojourners and Union League, Brooklyn. He is survived by his widow, Ida Boone (Rines) Simmons, whom he married in 1914, and by three daughters, Aline, Doris, and Elizabeth.

ORVILLE CAMPBELL SKINNER

Orville Campbell Skinner died unexpectedly on May 19, 1931. He had been a member of the A.S.M.E. since 1915 and also belonged to the American Institute of Mining and Metallurgical Engineers, American (and International) Society for Testing Materials, American Iron and Steel Institute, and Engineers Society of Western Pennsylvania.

Mr. Skinner, the son of Orville Bird and Helen (Campbell) Skinner, was born at Cleveland, Ohio, on January 19, 1872. He was graduated from the Case School of Applied Science, Cleveland, with a B.S. degree in 1894 and spent the next year in the Chemical Laboratory of the Otis Steel Company in Cleveland. After a year as chief chemist for Corrigan McKinney & Co., Cleveland, he went to Pittsburgh, Pa., to accept a similar position for the Schoenberger Steel Company. Subsequently he was made superintendent of the Open Hearth Department of that company, with which he remained until 1899. During the next two years he was manager of the Open Hearth Department of the Tidewater Steel Company at Chester, Pa. He became connected with the Standard Steel Works Company, Burnham Pa., a subsidiary of the Baldwin Locomotive Works of Philadelphia, in 1901, serving first as superintendent of the Open Hearth Department, and then successively as assistant superintendent, superintendent of manufacture, and works manager. In all of these positions his work included assistance in the design and installation of extensions and improvements. He resigned on April 1, 1930, to become president of the Lewiston (Pa.) Aircraft & Airways, Inc.

Mr. Skinner is survived by his second wife, Mrs. Flo (Fisher) Skinner, whom he married in 1929, and by two children, Mrs. Charlotte (Skinner) Neher and Orville Bird Skinner.

WILLIAM SMITH, SR.

William Smith, Sr., the son of William and Lillias Smith, was born at Glasgow, Scotland, on May 26, 1861. He attended the Tennents Industrial School at St. Rollox, Glasgow, and served an apprenticeship as a machinist in the toolroom and millwright department of the Hydepark Locomotive Works, Springburn, Glasgow. His first position was in the Caledonian railway shops of that city. From 1880 to 1883 he was employed by John Scott & Co., shipbuilders, of Greenock, Scotland. He then went to Paisley, Scotland, where he was engaged in 1884 in the erection of steam steering gear and sugar mill machinery. During the next two years he was employed as assistant foreman at the South Works and North Works, Forth Bridge, of Wm. Arroll & Co., Queensferry, Scotland.

Mr. Smith came to the United States in 1887, and from then until 1891, and again from 1893 to 1895, was millwright foreman for the Lower Union Mills of the Carnegie Steel Company, Pittsburgh, Pa. In the interim he was metal patternmaker for the Westinghouse Air Brake Company, of Pittsburgh and Wilmerding, Pa. In 1896 ant 1897 he was engaged in the erection of blast furnace machinery and mill machinery for the Keystone Bridge Company, Pittsburgh. He then went to Duquesne to serve as millwright foreman at the Duquesne Steel Works and later as assistant master mechanic of the Duquesne Blast Furnaces and Carnegie Steel Company. For six years beginning in 1900 he was connected with the Jones & Laughlin Steel Co., of Pittsburgh, as master mechanic at the Eliza Furnaces, and during the next seven years he held a similar position at the Soho Furnaces of the Company. He was next engaged as general master mechanic of the Pennsylvania Steel Company, Steelton, for two years. In 1917 and 1918 he was employed by the Midvale Steel Company, Coatesville, Pa., first as assistant to the superintendent, and later as general master mechanic. He accepted a similar position at the Coatesville Works of the Midvale Steel & Ordnance Co. in 1920 and remained there for three years. He was then connected successively with the New Process Copper Castings Company, Pittsburgh, of which he was president; the Lumen Bearing Company, Youngstown, Ohio; the Falcon Bronze Company, Youngstown, Ohio, as sales manager; the Lawrenceville Bronze Company, Pittsburgh, as sales manager; and the Copperweld Steel Company at Glassport, Pa. He was superintendent of the Rankin Works of this company in 1928 and 1929, and since then had held the position of maintenance superintendent of its Glassport Works.

Mr. Smith became a member of the A.S.M.E. in 1911. He also belonged to the Engineers Society of Western Pennsylvania and the Masonic fraternity. He is survived by his widow, Agnes (Patterson) Smith, whom he married in 1885, and by three sons. He died on November 10, 1930, at Glassport.

JOHN EDWIN STARR

John Edwin Starr, president of the Starr Engineering Company, consulting refrigerating engineers, New York, N.Y., died on June 27, 1931, at his summer home in Mattituck, Long Island, N.Y.

Mr. Starr was born in Litchfield, N.Y., on February 24, 1860, the son of John and Susan Starr. After being graduated from the Utica (N.Y.) Academy he went to St. Louis, Mo., where he entered the refrigerating field as draftsman for the St. Louis Automatic Refrigerating Company. Subsequently he designed and built refrigerating plants and cold storage warehouses for the Denver (Colo.) Automatic Refrigerating Company, and the Atlantic City (N.J.) Cooling Company, the Manhattan Refrigerating Company, New York, Kings County Refrigerating Company, Brooklyn, Baltimore (Md.) Refrigerating & Heating Co., and many other companies. He organized the Starr Engineering Company in New York in 1898.

In addition to the design and construction of refrigerating apparatus and plants Mr. Starr conducted tests of refrigerating machinery and insulating materials, made special investigations in his field, and contributed many articles to the technical publications dealing with refrigeration. He was the inventor of a low-temperature machine which attains temperatures of from 30 to 75 deg. below zero and of several absorption refrigerating devices. He was regarded as a leader in the establishment of refrigerating engineering among the sciences.

Mr. Starr presided at the first meeting of The American Society of Refrigerating Engineers, held in 1904, and served as president of the society for one year. In 1929 he was elected an honorary member of the organization. He was the American delegate to the International Congress of Refrigeration in Paris in 1908, and was the recipient in 1896 of the Franklin Institute Medal, in recognition of the work he had already done in refrigeration. He had been a member of the A.S.M.E. since 1905 and belonged also to the St. Louis Academy of Sciences, the London Institute of Cold Storage and Refrigeration, and the Engineers', Salmagundi, and Transportation clubs in New York. He is survived by a daughter.

JOSEPH S. STEPANOV

Joseph. S. Stepanov, research engineer for the Worthington Pump & Machinery Corp., Harrison, N.J., who died suddenly on April 10, 1931, was born at Ismail, Russia, on April 15, 1881. He secured his early education in Odessa and was graduated from the Imperial Institute of Technology in 1908.

During the first five years after his graduation Mr. Stepanov was employed by the Petrograd Metal Works Co., Inc., in the design and testing of steam turbines, boilers, and auxiliaries for power stations, waterworks, and ships. During the same period he gave lectures to evening classes on thermodynamics, steam turbines, internal combustion engines, and boilers. These lectures later appeared in book form under the title of "Steam Boiler Operation."

From 1913 to 1919 Mr. Stepanov was chief designer, production engineer, and chief engineer of the mechanical branch of the Russian Baltic Engineering & Shipbuilding Co., Inc., Reval, Baltic Sea. Prior to the World War he spent some time at Berlin with the General Electric Company studying developments in the design and construction of steam turbines; and at Hamburg with the Vulcan Works investigating progress in boilers and auxiliaries and power plants as a whole. During the War he designed, constructed, and tested machinery for destroyers, light cruisers, dry docks, submarine mine layers, and other equipment for the Russian Navy. He also had charge of the cost estimating and planning bureaus of the Russian Baltic Company. He devised a nomogram of chief dimensions of propellers, to facilitate the calculations for ship propellers; an article describing this nomogram was published in the Russian "Engineering News-Record" in 1915 and later included in programs of Russian institutions for engineering training. Following the War he helped to solve the problems connected with changing the work of the company from shipbuilding to locomotive repairing. He was appointed manager and a member of the board of directors by the Esthonian government. In 1919 Mr. Stepanov was made manager of the Ilmarine Metal Works, Inc., at Reval. He handled locomotive repair work for Esthonia and the construction of small engines.

Mr. Stepanov came to the United States in 1924 and was engaged as draftsman, designer, and experimenter by the Akimoff propeller Company, Philadelphia, Pa. The following year he worked on the design of reinforced-concrete arch bridges for the Hollywood Dredging & Construction Co., Hollywood, Fla., and then was engaged as designer by the City Engineering Department of Coral Gables, Fla. From 1927 to 1929 he worked on designs for dry quenching plants for heat utilization of hot coke, hot cement clinker, etc., for the Dry Quenching Equipment Corporation, New York, N.Y., a subsidiary of the International Combustion Engineering Corporation. He had been with the Worthington Corporation since that time and had suggested several refinements in design, including the diffusion ring of continuous curvature used in their "W" pumps.

Mr. Stepanov became a member of the A.S.M.E. in 1927 and had presented papers on centrifugal pumps and condensers at meetings of the Society. He was also active in the work of the American Standards Association.

Mr. Stepanov is survived by his widow, Mrs. Alexandra (Doemke) Stepanov.

ALBERT J. STRATMAN

Albert J. Stratman was born at Newport, Ky., on July 1, 1882, the son of John F. W. and Carolina (Kuehnle) Stratman. He studied mechanical drawing at the Ohio Mechanics Institute, Cincinnati, for four years, and took a mechanical engineering course through the International Correspondence Schools. He also served an apprenticeship as tool and die maker with Fay & Egan of Cincinnati. From 1906 to 1910 he was employed at the Baker Iron Works, Newport, Ohio. He then went to Ontario, Calif., where he was connected for eleven years with the Hot Point Appliance Company, now the Edison Electric Appliance Company. He worked for four years in the engineering and experimental departments, and during the latter part of his connection with the company was in charge of the heat treating department and metallurgical research. From 1921 to 1923 he assisted in the design and development of the "Silent" Rich lawn mower for the Rich Steel Products Company, Los Angeles. During the next year he was connected with the Teetor Adding Machine Company, Pomona, Calif., and subsequently with the Pacific Gas Radiator Company, the Pribnow Saw Sharpening Machinery Company, and the Simonds Saw & Knife Works, all of Los Angeles. For about four months prior to his death on March 15, 1931, he was superintendent and mechanical engineer for the Ballou Manufacturing Company, Ontario, Calif.

Mr. Stratman carried on extensive experiments in fuel atomization for internal-combustion engines, relative to which he was granted a patent. He served as a corporal in the Infantry in the Spanish American War, and formed a Home Guard Company during the World War at Ontario. For six years he served on the Ontario Board of Education. He became an associate member of the A.S.M.E. in 1922 and also belonged to the Masonic fraternity. He is survived by his widow, Christine Stolle Stratman, whom he married in 1904, and by three sons.

SAMUEL WESLEY STRATTON

Dr. Samuel Wesley Stratton died suddenly at his Back Bay, Boston, home of coronary occlusion on October 18, 1931, at the age of seventy. He had just dedicated a tribute to Thomas A. Edison, whose death occurred a few hours before. His tribute to Edison reads in part: "It seldom has fallen to the lot of any one man to be of such service to humanity. The world mourns that great benefactor." The tribute might very well have been written for Dr. Stratton.

Dr. Stratton was born in Litchfield, Ill., on July 18, 1861, the son of Samuel and Mary B. (Webster) Stratton. He spent his early life on a farm, where he acquired a habit of hard work and accumulated knowledge of the common things of life which formed the basis for his evaluation of the fitness of things. He liked all living creatures and folks most of all, but the mechanical features of farm life seemed to fascinate him.

He earned his way through the University of Illinois by doing various kinds of mechanical work. His warmth for machines was somewhat akin to his unconscious warmth for persons who had befriended him. Throughout his life he was never without his private shop where he could work with his own hands. This was recreation and exercise. Moreover, the shop was to him a retreat, like unto the mountain top for others. He cast his lot with the machine age wholeheartedly and at the same time he recognized that men were even more important than the machine.

The University of Illinois granted him his degree of Bachelor of Science in mechanical engineering in 1884 and afterward he went through the usual steps from instructor to professor of physics and electrical engineering. In 1892 he left his alma mater to become associate professor of physics and later professor at the University of Chicago, where he remained until 1901, when he was forty years old. In his previous position his research work, such as time sufficed, tended in the direction of the applications of physics to engineering. At Chicago he was enraptured with pure research as conducted by Michelson. He cherished the inspiration that he received from this great man and ever afterward he kept within the easy touch of his hand interferometers, Nichols prisms, quartz flats, and the like. Thus it is clear that he had the vision of the importance of pure research, as well as of engineering. He ever regretted that he could not have the pleasure of doing more work in both these fields with his own hands and often felt that sometime this privilege might come.

At forty Dr. Stratton was not marked as a genius either in teaching or research, but his foundations were well laid and his accumulated understanding of human nature was great.

Through the instrumentality of his college chum, Mr. Frank A. Vanderlip, who was Assistant Secretary of the Treasury, a new opportunity was opened. Almost single-handed Dr. Stratton engineered through the enactment of March 3, 1901, which created the Bureau of Standards out of the office of weights and measures. Secretary Lyman J. Gage invited him to become the first director. His vision of the usefulness of such a bureau was so clear that during his entire administration he was not handicapped by the organic act setting forth the functions and scope of activity. In 1903 the Bureau was transferred to the Department of Commerce. From the beginning he sensed the need of basic work in science and engineering as well as of testing, for the development of commerce and industry. He was one of the pioneers in this country in creating interest in basic research as an aid to industry, but near the end of his life he smiled ironically when a board of directors seemed to think that research was a "cure all." He knew that research was only an important essential need but that it called for rare talent and patience, working undisturbed by impatient executives and committees.

Dr. Stratton, like most great men, was modest, even approaching shyness. In building up the Bureau of Standards on the foundations that he had laid, he depended upon friends and genuine material interests to carry the structure forward. The technical needs of the Government during war time brought forth the large industrial building. The needs of aviation called for wind tunnels. Many unselfish and far-seeing men such as Ambrose Swasey and the late John Brashear were continually his advisers. He assisted and encouraged many organizations that seem to foster technical advance. With Dr. Walcott, there was started the National Advisory Committee for Aeronautics. He was a leader in the National Screw Thread Commission and also in the International Conference on Weights and Measures. Many other such organizations knew the value of his membership and quiet counsel. He served in the Spanish-American War as lieutenant.

His success at the Bureau of Standards may be measured by the output of the institution plus the material assets, and the fixation of ideals which it will probably always maintain. The elements which entered into this were many. His evaluation of men and his warm hold on the staff counted greatly. The conception of the tie-in of

basic research with the industries as well as with Government departments more than doubled the size of the Bureau and also doubled its output and recognition. The members of the staff were encouraged to maintain connections with engineering societies. He had been a member of The American Society of Mechanical Engineers since 1913, and served on the Power Test Codes Committee on definitions and values for seven years. He met every demand of the Society in providing men and equipment. Likewise he cooperated with other organizations, never unmindful of the interests of the Bureau.

In 1923 all New England seemed to glory with Massachusetts Institute of Technology when Dr. Stratton was elected president. By correspondence with Prof. Samuel C. Prescott, who was chairman of the faculty (1929-1931), I have learned that the Massachusetts Institute of Technology entered on an era of new progress in national usefulness, characterized by the extension of research in engineering and industry, as well as in pure science, and the expansion of the work of the Institute into new fields of applied science. Courses of instruction were offered which are not only meeting the demands of today but which prevision those of tomorrow. During his administration, departments or divisions of aeronautical engineering, hydraulics, physical metallurgy, municipal and industrial research, public health engineering, and ship operation were established.

Dr. Stratton saw at once the significance of the important contacts with great industries which had been previously made and which have resulted in the cooperative courses in electrical and chemical engineering, and with his support these have been fostered and made highly effective. Research has been greatly stimulated, and new laboratories for special fields of engineering investigation have been secured through the generosity of alumni and friends. Special opportunities have been made available for students of exceptional ability by the development of the so-called "honors groups," while a broadened range of general studies has provided varied cultural opportunity for all students. Foreign lecturers have brought the results of the best teaching, research, or practice abroad. Advisory departmental committees made up of men eminent in professional or business life have aided by wise suggestion in the solution of curricular questions.

In thus enhancing the opportunities for scientific training, Dr. Stratton was insistent that the personal or human factor should not be overlooked. A new group of comfortable and convenient dormitories for undergraduates has been made available through alumni cooperation. A new infirmary, given as a memorial to a former student and equipped with ample facilities for physical examination and medical service, has made possible close supervision of the health of students and proper care and treatment in case of accident or illness.

The foundation of a chair of humanics has made it possible for students to secure through lectures and discussion groups, some real knowledge of those matters dealing with the human relations which are essential factors in business and industrial life, and in the personnel problems of administration. These significant and liberalizing tendencies in technical training, as well as the continued insistence on the teaching of fundamental principles and the cultivation of a true spirit of research, are outstanding features characterizing the trend of the development of Technology under Dr. Stratton's presidency.

With the change in administrative organization in 1930 by which he became Chairman of the Corporation and Dr. Compton assumed the duties of President, Dr. Stratton's interest in educational problems remained undiminished. With this division of the onerous duties incident to the administration of this great school, the splendid way in which these two men cooperated for the development of the Institute redounds greatly to the credit of each. There existed between them a close bond, not only of community of interests and of ideals, but of mutual considerateness and deep affection.

Dr. Stratton took a deep and friendly interest in the undergraduates and easily won their highest respect and admiration. His door was ever open to them and they appreciated his true friendliness. He very skilfully exerted his influence on those who were leaders in student life, as well as in their professional interests. He saw in the undergraduate professional societies a great opportunity for training in the presentation and discussion of scientific papers and reports, as well as preparation for membership in the national engineering and scientific societies to which they would later become eligible, and to stimulate their interest in this important respect he personally provided, in 1931, worthy prizes to be won in competition between men from the various societies. This established a precedent for what will probably became an annual event of significance—the Stratton Prize competition.

Another little known act illustrating his vision was the establishment of a joint committee of students and faculty members for the mutual discussion of problems of curricular character, and of other matters in which both students and staff had a common interest. This committee has been highly serviceable, and has great potential value in bringing the two great groups together through recognized representatives who can clearly present the problems to be considered. While little publicity has been given to this and similar agencies for securing solidarity of aims and ideals in staff and student body, the results already indicate the far-reaching possibilities which Dr. Stratton had visioned.

The University of Cambridge honored him with the Doctorate of Science in 1909, Yale University gave him the D.Sc. degree in 1918, and Harvard later honored him with the L.L.D. degree. He was an officer of the Legion of Honor. There were many other honors and connections which only emphasize the social aspects of the great and yet retiring man.

F. C. Brown[1]

LAFAYETTE PINKNEY STREETER

Lafayette Pinkney Streeter, who died at Long Beach, Calif., on August 7, 1931, was born in Brooklyn, N.Y., on December 25, 1874, the son of Lafayette V. and Emma (Pinkney) Streeter. He prepared for college at the Columbia Institute and attended the Stevens Institute of Technology for three years, receiving a certificate with the class of 1900. In the following year, he entered the Mechanical Engineering Department of the New York Air Brake Company, Watertown, N.Y., as an assistant. He was appointed first assistant mechanical engineer a year from that time and, not long afterward, engineer of tests. In 1905 Mr. Streeter resigned from the New York Air Brake Company to become assistant air brake inspector for the Southern Pacific Company in Los Angeles, Calif. Four years later, he was promoted to the position of air brake inspector. He remained with that company until 1912, when he went to Chicago as air brake engineer for the Illinois Central Railroad. He returned to Los Angeles in 1925 and made his home there and at Long Beach until his death.

Mr. Streeter became a junior member of the A.S.M.E. in 1902 and an associate in 1903. He is survived by his widow, Cora (Doussang) Streeter, whom he married in 1918.

VICTOR O. STROBEL

Victor O. Strobel, president of the Rue Manufacturing Company, Haverford, Pa., was born on January 6, 1859, at Cincinnati, Ohio, the son of Mr. and Mrs. John Strobel. He attended high school in that city and subsequently the Ohio Mechanics Institute. From 1875 to 1879 he secured practical experience in the machine shop of Lambert & Gordon at Ironton, Ohio. He then secured a position as designer and chief draftsman for Witherow & Gordon at Pittsburgh, designers and constructors of blast furnaces and steel plants and agents for Whitwell firebrick hot blast stoves. In 1884 he spent six months in Europe compiling data for the manufacture of iron and steel. He returned to the United States to become secretary and treasurer of the firm of Gordon & Strobel of Philadelphia, designers and builders of blast furnaces and steel works. His company constructed the blast furnaces of the Tennessee Coal, Iron & Railroad Co. at Ensley, Ala., and many others in the South and West. In 1886 the firm was enlarged, its name becoming Gordon, Strobel & Laureau, and the business extended to small Bessemer steel and open-hearth plants. About this time, Mr. Strobel also became treasurer of the Philadelphia Engineering Works, Ltd., a position which he held until 1898. In that year he was appointed general manager of the Crane Department of the Niles-Bement-Pond Company. He resigned this position in 1925 when he became president of the Rue Manufacturing Company.

Mr. Strobel became a member of the A.S.M.E. in 1892. His death occurred on October 1, 1931. Surviving him are his widow, Annie S. (Harbaugh) Strobel, and a daughter, Mrs. Springer Starr.

GEORGE FILLMORE SWAIN

George Fillmore Swain, who won distinction both as a teacher of civil engineering for nearly fifty years and as a consulting engineer, died at his summer home at Holderness, N.H., on July 1, 1931. In addition to his teaching and consulting work Professor Swain had served on many important commissions and written a number of books on civil engineering; he was recognized as one of the leading authorities in the United States on that subject.

Professor Swain was born on March 2, 1857, at San Francisco, Calif., the son of Robert Bunker and Clara Ann (Fillmore) Swain. After receiving an S.B. degree from the Massachusetts Institute of Technology in 1877, he went to Berlin, where he studied at the Polytechnic School for three years. Returning to this country, he entered the teaching field as instructor in civil engineering at the Massachu-

[1] Chairman, Scientific Exhibits Committee, American Association for the Advancement of Science, Washington, D.C.

setts Institute of Technology. He was made assistant professor in 1883 and associate professor two years later. In 1887 he was appointed Hayward professor of civil engineering and head of the department. During these early years at Cambridge he spent several summers at Lowell, Mass., in the Offices of Locks and Canals on the Merrimac and did some engineering work for Essex County at Lawrence, Mass. From 1880 to 1883 he was hydraulic expert for the tenth United States census, reporting on water power of the Atlantic slope.

In 1909 Professor Swain became Gordon McKay professor of civil engineering at Harvard University and he held this post for twenty years, until a shock in 1929 necessitated his retirement. Perhaps no other man has contributed so much to the development of correct methods of both the presentation and assimilation of engineering knowledge.

The Massachusetts Railroad Commission was the first of many bodies to avail itself of Professor Swain's knowledge of railway engineering. He was consulting engineer to the Commission from 1887 to 1914, during which time he had supervision of bridges in the state and made many important valuations. In 1893 and 1894 he was a member of the Boston Subway Commission and from then until 1918 a member of the Boston Transit Commission, serving as its chairman during the last five years of that period. The subway system of the city was begun in 1895, and Professor Swain was largely responsible for its development.

His appraisal work extended to the New York, New Haven & Hartford Railroad, on whose assets and liabilities he reported to the Massachusetts State Commission in 1910 and 1911, and he made like valuations of the New York Central Railroad and Chicago Elevated Railway in 1911 and 1912. In 1916 he was engaged by East Orange, N.J., to serve as an expert on the elimination of grade crossings in that city by the Delaware, Lackawanna & Western Railroad, and also by the Royal Commission on Railways and Transportation to make valuations of certain Canadian railways. The city of Rochester, N.Y., consulted him in 1921 and 1922 in connection with subway construction, and during the next two years he was a member of two engineering boards, representing New York, to report on New York and Brooklyn elevated railways. In 1927 he again served on a committee on the New York transportation problem. Many other states and municipalities, as well as private concerns, sought his help as a consulting engineer in solving problems relating to railway and highway crossings, subways, and bridge and dock constructions, and he was frequently in demand to give expert testimony in cases involving civil engineering.

Professor Swain also served on a number of commissions and boards dealing with matters other than railway engineering, including the Commission to Revise the Building Laws of Boston (1904), United States Conservation Commission (1909), Commission on Graduate Instruction at the United States Naval Academy, as chairman (1916), and Board of Arbitration on Reconstruction of the Galveston Causeway (1916). In 1918 he was a member of a delegation of American engineers invited to discuss rehabilitation problems at the French Engineering Congress. A Franco-American Engineering Committee was formed on which all the American delegates were asked to serve. In 1921 he was in charge of an investigation and report on the Toronto waterfront problems for the Canadian Pacific Railroad and Grand Trunk Railroad.

The first award of the Benjamin G. Lamme gold medal, established by the Society for the Promotion of Engineering Education "for accomplishment in technical teaching or actual advancement of the art of technical training," was made to Professor Swain in 1928. He received an honorary degree of LL.D. in 1906 from New York University and in 1918 from the University of California.

Professor Swain had a continuous record of important contributions to engineering literature since 1880. In addition to many papers for engineering periodicals and treatises for students he wrote a number of books, including "Conservation of Water by Storage" (1914), "How to Study" (1916), "The Young Man and Civil Engineering" (1924), "Strength of Materials" (1924), "Fundamental Properties of Materials" (1924), and "Stresses, Graphical Statics and Masonry" (1927).

Professor Swain was director of the American Society of Civil Engineers in 1901–1903, vice-president in 1908–1909, and president in 1913, and was made an honorary member of that society in 1929. He had also served as president of the Society for the Promotion of Engineering Education (1894–1895), and of the Boston Society of Civil Engineers (1896–1897). He became a member of the A.S.M.E. in 1883, was a fellow of the American Academy of Arts and Sciences, honorary member of the American Institute of Steel Construction, and a member of the National Academy of Sciences, New England Railroad Club, American Institute of Consulting Engineers, Engineering Institute of Canada, Institution of Civil Engineers (Great Britain), American Railway Engineering Association, American Electric Railway Association, American Society for Testing Materials, New England Water Works Association, and the American Forestry Association. His clubs included the Boston Art, Boston City, Harvard, University, Union, St. Botolph, and Commercial. He had served as a member of the Board of Judges of the Hall of Fame, New York, since it was first established.

Professor Swain was married three times. He is survived by his widow, Mary A. (Batchelder) Rand Swain, of Brookline, Mass., and by two daughters and a step-daughter.

WILSON ERWIN SYMONS

Wilson Erwin Symons, consulting engineer, well known in the railroad field, died of heart failure on May 1, 1931, at the Elks Club, New York, N.Y., where he hade made his home for the past fifteen years. He had been a member of the A.S.M.E. since 1899 and served on its Finance Committee in 1919. In the same year he was also treasurer of the American Welding Society. Other organizations to which he belonged were The Franklin Institute, the Western Society of Engineers, the American Railway Association (Mechanical Division), the American Railway Master Mechanics Association, and the Master Car Builders Association of America. He was also a member of the Society of Friends and the Odd Fellows, as well as of a number of clubs.

Mr. Symons was born at Farmland, Ind., on December 18, 1858. He attended the public schools of Wayne County, Ind., and learned the machinist's trade with the Nordyke & Marmon Co., which moved from Richmond to Indianapolis during his apprenticeship with it. He was employed in 1878 and 1879 as a machinist at the Atlas Engine Works, Indianapolis, and during the next two years at the Columbian Iron Works, Chicago. He was also connected for a time with the Chicago, Rock Island & Pacific Railway in a similar capacity.

For four years beginning in 1881, Mr. Symons was chief engineer in the Merchant Marine Service on the Great Lakes. During the next three years he was locomotive engineer for the Wisconsin Central Railway Company, the Atlantic & Pacific Railway, and the Atchison, Topeka & Santa Fé Railway Co. After being operating engineer for a year at a Chicago steam electric plant, he became division foreman for the Atchison, Topeka & Santa Fé Railway Co. at Chanute, Kan., later being promoted to the position of master mechanic at Raton, New Mexico. He went to Mexico as master mechanic of the Mexican Central Railroad at San Luis Potosi, in 1895. His work during the next two years as mechanical expert for the Galena Signal Oil Company took him to various parts of the United States, and to England and France. Upon returning to this country he was engaged for four years by the System Railways at Savannah, Ga., as superintendent of motive power and equipment. From there he went to Cleburne, Tex., to become a mechanical superintendent for the Gulf, Colorado & Santa Fé Railway Co. In 1904 and 1905 he was superintendent of machinery for the Kansas City Southern Railway Company, at Pittsburgh, Kan.

In 1906 Mr. Symons entered the consulting field as a member of the firm of Burt & Symons in Chicago. He retained this connection for ten years. He was also made president of the Pioneer Cast Steel Truck Company, of Chicago, in 1909, superintendent of motive power and machinery for the Chicago Great Western Railway, St. Paul, Minn., the following year, and superintendent of motive power for the San Antonio & Aransas Pass Railway Co., San Antonio, in 1913. His partner, Mr. Burt, was ex-president of the Union Pacific System. The firm handled problems in connection with the rehabilitation of railways, their valuation, rate cases, etc. In 1911 Mr. Symons delivered an address before The Franklin Institute on "The Practical Application of Scientific Management to Railway Operation." This was inspired by attacks on railway efficiency made by opponents to requests of carriers for an advance in rates, at hearings in 1910 and 1911.

From 1916 to 1919 Mr. Symons was vice-president of the Wilson Welder & Metals Co., Inc., at New York. Since then he had carried on a consulting practice in that city and had also served during part of the time as associate editor of the engineering publications of the Angus Sinclair Company, especially of *Railway and Locomotive Engineering*. During his connection with the System Railways at Savannah, Mr. Symons designed a locomotive that made a speed record of 120 m.p.h. on a special run made for the purpose of securing a Government mail contract. During the latter part of his life he spent a good deal of time in developing his patents on appliances for steam locomotives and other rolling stock of railroads, such as draft gears and locomotive exhaust nozzles. He was consulting engineer for the Congressional committee conducting an investigation regarding the adoption of the metric system, and had been consulted as an

expert in regard to the moving of the shops of the Boston and Maine Railroad from Concord, N.H.

WILLIAM HINMAN TABOR

William Hinman Tabor, time-study chairman for the Gilbert & Barker Manufacturing Co., West Springfield, Mass., died from septic poisoning on October 22, 1931.

Mr. Tabor was born at Elmira, N.Y., on April 26, 1892, the son of Leroy and Anna F. Tabor, and attended the public schools there. The family moved to Philadelphia in 1907, and Mr. Tabor was employed as a toolmaker by The Tabor Manufacturing Company of that city for several years. At the same time, he attended night classes in scientific management at Drexel Institute. The family returned to Elmira for the year 1910-1911, during which time he was under instruction in the toolroom of the Willis-Morrow Company there. He was again employed by The Tabor Manufacturing Company when the family relocated in Philadelphia and continued his work there until 1913, when he was appointed instructor in scientific management and in machine shop practice at The Pennsylvania State College. He resigned his position in 1916 to become associated with the Winchester Repeating Arms Company of New Haven, Conn. For three years he was connected with its tool division as industrial engineer, for one year was production superintendent of the Forged and Edged Tool Division, and for a year production engineer working on cost reduction by improving manufacturing methods, tool equipment, and factory layouts. During these years, he also conducted consulting work as a member of the firm of Diemer & Tabor. In 1922, he returned to Philadelphia to install production control and time-study standards for the Miller Lock Company. Upon the completion of this work in 1923, he became assistant to the general manager of the A. J. Deer Company, Hornell, N.Y.

His association with Gilbert & Barker dated from 1925. In addition to the regular time-study and job analysis work for which he was responsible, he assisted in the selection and layout of factory equipment and in improvements in tools and methods. He was also connected in 1925 with the time-study and rate division of the Willis-Morrow Company.

Mr. Tabor joined the A.S.M.E. as a Junior in 1914 and became an associate member in 1920. He is survived by his widow, Maud E. (Hinmand) Tabor, whom he married in 1910.

GUSTAVE ROBISHER TUSKA

Gustave Robisher Tuska, consulting engineer and lecturer of recognized authority on railroad engineering and maintenance, was born in New York, N.Y., on July 15, 1869. His parents were Adolph and Elsie (Robisher) Tuska.

Colonel Tuska received the degree of Bachelor of Science from the College of the City of New York in 1888 and a master's degree from the same institution three years later. In 1891 he also was graduated from the School of Mines of Columbia University as a civil engineer.

For his first position following graduation Colonel Tuska secured employment as assistant engineer in the drawing room of the Link-Belt Engineering Company of Philadelphia, Pa. Early in 1892 he returned to New York as bridge engineer for the Long Island Railroad Company. The following year he took up the dual role of instructor in bridge design and masonry construction at Columbia University, and consulting engineer. After three years at Columbia he decided to give all of his time to consulting work and did not return to lecturing at Columbia until 1907. His later lectures dealt with the subject of municipal engineering and waste disposal.

In consulting work Colonel Tuska served both public and private enterprises. Between 1893 and 1899 he had a variety of assignments, including the design and rebuilding of the Lonesome Valley Viaduct of the Knoxville, Cumberland Gap & Louisville R.R. and the Stone Brook Viaduct of the Central New York & Western R.R., the design of the dome of St. Matthews Church, Washington, D.C., a pier and pier shed for the New York Central Railroad at New York, an elevator plant for Kohler's Brewery in that city, and a plant for the Atlantic Fisheries Company at Cape Charles. During the last three years of this period he was chief engineer in charge of design, inspection, and maintenance of terminals, wharves, and tracks for the Panama Railroad and superintending engineer for the Panama Steamship Company. For several years he was also engineer to the Health Department of the City of New York.

Subsequent to 1900 Colonel Tuska was for many years president and chief engineer of the American Process Company, builders of plants handling waste products, and of the Atlantic Construction Company, constructors of plants for manufacturing oils and ammoniates. His consulting work included water power plants in New Hampshire, a gas plant in Syracuse, N.Y., piers in New York, and trolleys in Manchester, N.H., and Richmond, Va. Other projects took him to St. Louis, Mo., Chicago, Ill., Buffalo, N.Y., and Washington, D.C. He was elected president and director of the International Engineering Corporation in 1923. His wide experience caused him to be called upon for expert testimony and investigations of patents and his work also included the examination of boiler plants and electric lighting and central steam heating plants.

When the United States entered the World War he joined the Engineers Corps as a major. He was attached to Camps Lee and Humphreys in Virginia and later assigned to a special staff and worked with the director-general of military railways. In 1919 he was on the staff of the Chief of Engineers in Washington, D.C. He was made a Lieutenant-Colonel of Engineers, in the Officers Reserve Corps, U.S.A., in 1923.

Colonel Tuska also rendered service on several government commissions. During 1918 he was a member of the steel committee of the War Industries Board and after the close of the War was a member of the United States Mexican Commission. He was a delegate to the second and third Pan-American congresses.

Much of his experience was recorded by Colonel Tuska in papers for the engineering and scientific organizations of which he was a member. He was a fellow of the American Association for the Advancement of Science, and belonged to the American Academy of Political and Social Science, National Institute of Social Science, American Society for Municipal Improvements, American Public Health Association, Pan-American Society, Society of Naval Architects and Marine Engineers, American Society of Civil Engineers, and The American Society of Mechanical Engineers, which he joined in 1900. He was a life member of the Metropolitan Museum of Art and American Museum of Natural History (New York), a trustee of the Allied Patriotic Societies, director of the Technical Institute of New York, and Past Commander of the New York Commandery of the Military Order of Foreign Wars of the United States. He belonged to the Phi Beta Kappa, Theta Delta Chi, and Pi Gamma Mu fraternities and Kings Crown of Columbia University. His clubs included the Bankers, Lotos, Century, Baltusrol, and Engineers' in New York, Cosmos, Washington, D.C., and Union Interalliée in Paris.

Despondence because of poor health led Colonel Tuska to take his life by shooting on May 28, 1931. His widow, Isabel (Pappenheim) Tuska, whom he married in 1902, survives him.

CHARLES REGINALD VAN TRUMP

Charles Reginald Van Trump was born near Baltimore, Md., on April 14, 1867. He was graduated from Cornell University with an M.E. degree in 1889. Prior to, and during his college days, Mr. Van Trump secured practical experience in the drawing room and shops of the Trump Bros. Machine Co. Following his graduation, he entered the Instrument Shop at Cornell and later spent some time in the Testing Laboratory of the Edison Machine Works at Schenectady. At the beginning of 1890, he took charge of the Electrical Department of the central station at Wilmington and was subsequently promoted to the position of general superintendent there. In 1891 he accepted a position as engineer and manager of the Wilmington City Electric Company.

In association with his father, Mr. Van Trump conducted experimental work in electric lighting, during which he lost his eyesight. Through his efforts, the Delaware Commission for the Blind was organized and The Blind Shop founded in Wilmington. The remainder of his life, until his death in 1924, was devoted to teaching the blind people of Delaware how to become self-supporting.

Mr. Van Trump was a life member of the A.S.M.E., which he joined as a junior in 1893, and in which he attained full membership five years later.

AUGUSTAS THEODORE VICK

Augustas Theodore Vick, who was killed in an automobile accident near Houston, Texas, on November 7, 1931, had been a member of the A.S.M.E. since 1911. He was active in the work of the Houston Section, and a member of its Executive Committee.

Mr. Vick was born on April 11, 1877, at Marion, Ill., the son of Monroe Tyler and Elvyra R. (Roberts) Vick. He attended high school at Anna, Ill., and served an apprenticeship in the machine and repair shops of H. M. Detrich of that place. In 1903, he entered the employ of the Western Electric Company, in St. Louis, and was sent to Desoto, Mo., as superintendent of the Consumers Electric & Power Co. He was next connected with the Hoyt Metal Companies, as chief engineer and electrician of their plant at Granite City, Ill. From 1905 to 1907 he was stationed in the Test Department of the Hawthorne, Ill., plant of the Western Electric Company. In 1907

and 1908, he was chief engineer at the plant of the American Car & Foundry Co. at Madison, Ill.

For some years, beginning in 1908, Mr. Vick was identified with the Missouri, Kansas & Texas Railway Co. His headquarters were at Overland, Mo., and his duties included the design and specifications for a number of new plants for the company. He went to Houston in 1916, and shortly afterward became manager for the P. E. Newberg Electric Company of that city. The contracting firm, A. T. Vick Company, of which he was president, was formed in 1919.

Mr. Vick is survived by his widow, Mrs. Sue. B. (Marshall) Vick, whom he married in 1916.

GEORGE A. VOLZ

George A. Volz, demonstrator and survey man for Cincinnati Grinders, Inc., Cincinnati, Ohio, died on September 19, 1931. He is survived by a son, Milton R., and a daughter, Helen R. Volz.

He was born at Cincinnati on October 2, 1894, the son of Joseph H. and Anna (Busam) Volz. He received training as a machinist and tool and die maker in various plants in which he was employed from the age of fifteen. In 1918 he was engaged as a model maker at the Eagle Manufacturing Company of Cincinnati, developing working models from patent drawings and specifications. He was successively employed as toolmaker by the Van Blerck Motor Company, Monroe, Mich., and the Weis Fibre Container Corporation of that city, the Lincoln Tool Company, the Blakeley Manufacturing Company, and the Briggs Manufacturing Company, all of Detroit, as tool and die maker from 1919 to 1925. Ill health in 1926 kept him from steady employment. The following year he worked for a time for the American Can Company and since then had been employed by the Cincinnati Grinders, Inc.

Mr. Volz was an associate member of the A.S.M.E., which he joined in 1930.

LUCIUS MORTON WAINWRIGHT

Lucius Morton Wainwright, president of the Diamond Chain & Manufacturing Co., Indianapolis, Ind., who died on February 24, 1931, was born at Noblesville, Ind., on January 4, 1860. His parents were William A. and Hannah Guy (Pontius) Wainwright.

Mr. Wainwright was a salesman for bicycles for a number of years after he was graduated from the Noblesville High School. For two years he also was in charge of construction for the Pipe Line Department of the Ohio Oil Company, Lima, Ohio. In 1890 he organized the Central Cycle Manufacturing Company, Indianapolis, and until 1898 served as its president and designed and superintended the manufacture of Ben Hur bicycles. Two years later he took charge of the Diamond chain factory of the American Bicycle Company at Indianapolis and developed pitch chains for the transmission of power. In 1905 he organized the Diamond Chain & Manufacturing Co., which took over the Diamond factory, and as its president and general manager engaged in the development and manufacture of chains and sprockets for the transmission of power and the production of automatic machines for making chains.

Mr. Wainwright was twice married. His first wife, Victoria Gray, of Noblesville, died in 1893. He is survived by his second wife, formerly Edith Palmer, of New York, whom he married in 1900, and by one son, Guy A. Wainwright, vice-president of the Diamond Company.

Among the organizations to which Mr. Wainwright belonged were the A.S.M.E., which he joined in 1907, the Society of Automotive Engineers, and a number of clubs, including the New York Yacht and the Manhasset Bay Yacht clubs. For more than twenty years he was treasurer of the Motor & Accessory Manufacturer's Association. He was a director of the Fletcher American National Bank and of the Morris Plan Company. He died at his winter home in Miami, Fla., after a long illness.

HENRY HEILEMAN WAIT

Henry Heileman Wait, who died on November 16, 1931, was born in Chicago, Ill., on October 27, 1869, the son of Horatio Loomis and Chara Conant (Long) Wait. He was graduated from the Chicago Manual Training School in 1886 and received a B.S. degree in electrical engineering from the Massachusetts Institute of Technology five years later. In 1891 and 1892 he was employed by the Economic Electric Manufacturing Company, Brockton, Mass., making a special investigation of incandescent lamps. From then until 1905 he was associated with the Western Electric Company in Chicago, first as draftsman and subsequently as assistant electrical engineer in the dynamo department and as chief engineer of the power apparatus department. From 1906 and 1913 he was president of the Rateau Turbine Company in Chicago. During the next four years he engaged in design and manufacture of the Wait bulldog turbines and dynamos. Since 1917 he had been identified with the Hill Pump Company of Anderson, Ind., which was merged with the Midwest Engine Company in 1918, manufacturing the Wait bulldog turbines.

Mr. Wait was especially active in the evolution and improvement of dynamos, both of bipolar and multipolar types, including type "L" Western Electric multipolar direct-current generators. He was the patentee of a varipolar motor or dynamo and semi-automatic machine for winding small armatures, spools, etc., as well as improvements on arc lamps. He was also the inventor of the Wait turbogenerator.

Mr. Wait became a member of the A.S.M.E. in 1905. He also belonged to the American Institute of Electrical Engineers, the Institution of Electrical Engineers, and the Société Internationale des Electriciens, and was a lieutenant in the Illinois Naval Reserves from 1898 to 1905. He is survived by his widow, Edna (Kimball) Wait, whom he married in 1913, and by three sons.

GEORGE LLOYD WALL

George Lloyd Wall, retired lieutenant-colonel, U. S. Army, Washington, D.C., died on May 30, 1931. Colonel Wall was born at Hoboken N.J., on January 1, 1872, the son of Edward B. and Sarah B. Wall. He received an M.E. degree from the Stevens Institute of Technology in 1893. During the next two years, he served an apprenticeship as a machinist and worked in the drawing room of the Southern Railway Company at Knoxville, Tenn., and for the next year he was resident inspector of the Department of Tests of that road.

In 1897 and the first half of the following year Colonel Wall was employed by the Hazelton Boiler Company. He then became motive power inspector for the Pennsylvania Company, with which he remained for several years. For a time he was assistant foreman of the erecting shop and roundhouse of the company at Ft. Wayne, Ind., and later, general foreman of the Erie and Ashtabula Division, reporting direct to the superintendent of motive power. He was assistant engineer of motive power at Ft. Wayne in 1903 and subsequently director of tests for the P.R.R. system during the Louisiana Purchase Exposition.

For ten years, beginning in 1906, Colonel Wall was associated with the Lima Locomotive & Machine Co. and its successor, the Lima Locomotive Corporation, of Lima, Ohio, serving as its vice-president from 1913 to 1916. During the following year, he was chairman of the Subcommittee on Designs and Specifications for Standard Freight Car Equipment of the American Railway Association.

When the United States entered the World War in 1918, Mr. Wall was commissioned a major in the Ordnance Department and stationed at the Watertown Arsenal, Watertown, Mass. He was made a lieutenant-colonel the following year and served successively at Camp Eustis, Va., the Erie Proving Ground, LaCarne, Ohio, the Philippine Ordnance Department at Manila, and the Frankford Arsenal in Philadelphia, where he was Commanding Officer in 1928 and 1929. He had retired from service and established his home in Washington a short time before his death. His wife, Myra K. (Crane) Wall, predeceased him.

Colonel Wall became a junior member of the A.S.M.E. in 1897 and was promoted to full membership in 1904. He belonged to a number of clubs, including the Union League.

HAROLD MERRIOTT WALMSLEY

Harold Merriott Walmsley, a member of the A.S.M.E. since 1917, died on January 5, 1931, at the Christ Hospital in Cincinnati, Ohio, from embolism following an operation for appendicitis.

Mr. Walmsley was born in Chicago, Ill., on March 11, 1880, the son of William and Mary (Wrigley) Walmsley. He was graduated from Purdue University with a B.S. degree in electrical engineering in 1905. During his college vacations he worked as a draftsman for the Western Electric Company, Chicago, as construction foreman for the C.F. & I. Co., Pueblo, Colo., as engineer in the Maintenance of Way Department of the N.Y.C. & H. R.R., at Buffalo, and as construction engineer for the South City Chicago Railway.

Following his graduation Mr. Walmsley took an apprentice engineering course at the General Electric Company, Schenectady, N.Y. In 1909 and 1910 he was engaged by the Commonwealth Edison Company, Chicago, as construction engineer at two of its stations. After completing this work he became associated with Sargent & Lundy and the American Gas & Elec. Co. He had complete charge of the construction of a new boiler plant for the Canton (Ohio) Electric Company, a new 9,000 kw. station for the Wheeling (W. Va.) Electric Company, and a new 6,000 kw. station for the Ohio Light & Power Co., Newark, Ohio. In 1914 and 1915 he engaged in contracting and engineering as a member of the firm of the

Steam Electric Engineering Company, at Wheeling, and during the next two years was resident engineer for Sargent & Lundy in charge of a 120,000 kw. plant for the Union Gas & Elec. Co., Cincinnati, until 1918, when he went to Tulsa, Okla., as resident engineer for Sargent & Lundy, in charge of a new power plant for the Oklahoma Power & Light Co.

Mr. Walmsley returned to Cincinnati in 1919 to become chief engineer for the Post-Glover Electric Company, with which he remained until 1925. From then until 1929 he was district sales manager for the Champion Switch Company and Jeffrey-DeWitt Insulator Company, Cincinnati, and since that year had maintained his own office for consulting work and sales engineering in Cincinnati.

Mr. Walmsley's widow, Josephine H. Walmsley, survives him.

EDGAR CARRUTH WALTHALL

Edgar Carruth Walthall, who was killed in an aeroplane accident on August 21, 1931, was born in Atlanta, Ga., on January 19, 1903, the son of W. P. Walthall. He attended the Technical High School there and was graduated from the Georgia School of Technology with a B.S. degree in mechanical engineering in 1924. After a short time as draftsman for Warren Webster & Co., at Atlanta, he secured a position as sales engineer for the Boiler Equipment Service Company of that city. In 1929, he joined the sales force of the Combustion Engineering Corporation and was connected first with its Atlanta office and later was made manager of the New Orleans branch office.

Mr. Walthall became interested in aviation about two years before his death. In 1930, he enrolled for a training course at Kelly Field, San Antonio, Texas, from which he was graduated in June, 1931, and was commissioned a lieutenant in the Air Corps. He had taken part in recent aerial maneuvers along the Eastern Seaboard and, at the time of his death, was stationed at Fort Crockett, Galveston, Texas. Together with another member of the Army Air Corps, Lieutenant Walthall was making low-altitude observations when the plane in which they were flying struck a power line and dropped into the Brazos River, near Freeport, Texas.

Lieutenant Walthall became a junior member of the A.S.M.E. in 1927, and belonged to a number of social and technical clubs.

GEORGE AUSTIN WARD

George Austin Ward, design engineer for the Wilputte Coke Oven Corporation, New York, N.Y., died at the Mountainside Hospital, Montclair, N.J., on January 19, 1931, of complications following an operation. He had been in poor health since Christmas.

Surviving Mr. Ward are his widow, Mrs. Susie G. Ward; a son, Dr. Raymond S. Ward, of Montclair; and a daughter, Mrs. Edwin R. Reed, of Bloomfield, N.J.

Mr. Ward was born on June 7, 1864, at Worcester, Mass., the son of Austin W. and Sarah Ann Ward. After his graduation from the Worcester Polytechnic Institute in 1887, with a B.S. degree, he did drafting and installation work for the Worcester Elevator Company and the Morgan Construction Company until 1893. During the next six years he was at Springfield, Mass., as mechanical engineer and erecting superintendent for the Springfield Foundry Company, elevator and pump builders and founders. From 1899 until 1901 he was on the staff of the engineering department of the Electric Vehicle Company, Hartford, Conn. He had charge of the design and installation of equipment of a maintenance shop for the New York Transportation Company. During the next two years he was in the engineering department of the McAdams & Cartwright branch of the Otis Elevator Company, New York.

From 1903 to 1910 Mr. Ward engaged in consulting and design work, particularly in connection with patent litigation. After that he had five years' experience as assistant engineer and chief draftsman of the Pearson Engineering Corporation, handling power house design and equipment on Mexican, Brazilian, and Spanish properties. In 1915 and 1916 he had charge of the appraisal squad working on the electrical and mechanical equipment of the Hazelton (Pa.) branch of the Lehigh Valley Coal Company. He had been with the Wilputte Coke Oven Company, contractors for coke ovens with by-product equipment, since that time.

Mr. Ward became a member of the A.S.M.E. in 1919. He was one of the oldest members of the Montclair Glee Club, and belonged to the Republican Club and First Baptist Church there.

HENRY CHRISTIAN WEIKEL, JR.

Henry Christian Weikel, Jr., who died at Baltimore, Md., on July 17, 1931, was born in that city on March 5, 1905. His parents were Henry Christian and Ethel Louise (Stewart) Weikel. He studied four years at the Polytechnic Institute of Baltimore and three years at Johns Hopkins University. In 1925 he entered the employ of the United States Printing & Lithograph Co. at Baltimore, of which he was assistant superintendent at the time of his death. Mr. Weikel's duties with the company during the first two years related to both mechanical and electrical construction and maintenance work. In 1928 he was appointed production engineer and made improvements in design in order to increase production. He had applied for a patent for testing apparatus.

Mr. Weikel became a junior member of the A.S.M.E. in 1929. He is survived by his widow, Elizabeth (Babylon) Weikel.

ROBERT WELER

Robert Weler, of whose death in Paris the Society has been notified, was born at Bayonne, France, on March 15, 1890. He attended the Lyceum of Bordeaux and for several years traveled and studied in various countries. From 1914 to 1918 he was a member of the French Flying Corps. After the close of the war he established the Weler Motor Car Company at Levallois, Perret, France. After two years, during which he worked on the design and production of a cyclecar, he accepted a position as production engineer for the Citroën Motor Car Company in Paris. He was later made assistant to the chief engineer of that company. The Boyer-Weler Engineering Company of Paris and New York was organized in 1924.

Mr. Weler became a member of the A.S.M.E. in 1927.

EDWARD ALSTON WHALEY

Edward Alston Whaley, who died on November 6, 1931, was born at Suffolk, Va., on November 27, 1892. He was graduated from Princeton University in 1914 as a civil engineer. During his college years, he engaged in mill construction and work in lumber camps, and, for a year following his graduation, was superintendent of construction for Baker & Brinkley, general contractors of Norfolk. He then became machinery salesman for W. M. Whaley & Co. of that city, where he remained two years. In 1917, he entered the United States Navy as Lieutenant in charge of construction of new shops at the Norfolk Navy Yard. Later, he designed shops for the Bureau of Yards and Docks at Washington, and was sent overseas to construct naval air stations. After the close of the War, he established the Edward A. Whaley & Co. of Norfolk, and subsequently the Whaley Aircraft & Engineering Co. This plant specialized in the production of certain types of airplane instruments, machinery, etc., largely for the United States Army and Navy.

Mr. Whaley became an associate member of the A.S.M.E. in 1924. He is survived by his mother, Fletcher (Norfleet) Whaley. His father, William Mitchell Whaley, died in 1926.

JOHN RAMSEY WILDE

John Ramsey Wilde, chief engineer of power plants for The Detroit Edison Company, died of pneumonia on March 29, 1931, in Detroit. He is survived by his widow, Margaret (Maloney) Wilde, whom he married in 1889, and by three daughters and a son.

Mr. Wilde was born in New York on September 20, 1865. His early education was secured in Toledo and subsequently he served an apprenticeship as a machinist with the Dry Dock & Detroit Specialty & Machine Co. In 1886 he entered the employ of the Edison Illuminating Company as assistant erecting engineer. He remained with this company and its successor, The Detroit Edison Company, until his death, serving as chief engineer of its Willis Avenue Station from 1891 to 1907, and as chief assistant engineer of the Delray Power Plants during the next six years. He was made chief engineer of power plants in 1913.

Mr. Wilde became a member of the A.S.M.E. in 1915 and also belonged to the Detroit Engineering Society and to the Masonic fraternity.

TURNER A. WILKINSON

Turner A. Wilkinson, for some years connected with the Erie City Iron Works, Baltimore, Md., was born in that city on February 26, 1864. His parents were Thomas Strike and Frances (Bennett) Wilkinson. He attended the Baltimore City College, and in 1881 became assistant superintendent of the Rasin Fertilizer Company in Baltimore, in charge of steam plant and mill machinery. He remained with this company until 1893, when he took charge of the foundry and machine shop, building watertube boilers for the Campbell Zell Company of Baltimore. Ten years later he accepted a position with the Erie City Iron Works, directing erection work. Subsequently he served as manager of the sales office, and at the time of his death on April 6, 1931, he was district sales agent for the company.

Mr. Wilkinson became an associate of the A.S.M.E. in 1918. He is survived by his widow, Louise B. (Hellweg) Wilkinson, and by one daughter.

HARVEY D. WILLIAMS

Harvey D. Williams, who was awarded the Howard N. Potts Gold Medal by The Franklin Institute for his invention of the hydraulic variable speed transmission used by the U.S. Navy for operating gun turrets, airplane hoists, steering vessels, and for various applications in submarines, died on March 9, 1931. He had retired from active professional work, owing to failing health, and had been seriously ill for several months.

He was born in Shaftsbury, Vt., on February 24, 1864, the son of Lewis and Sarah J. (Sleeper) Williams, and received his early education in the public schools of Bennington, Vt., and his technical training at Stevens Institute of Technology, from which he was graduated in 1885 with the degree of M.E. He then entered the employ of the Yale & Towne Manufacturing Co. at Stamford, Conn.

In 1888, he joined the faculty of Sibley College, Cornell University, where he taught mechanical drawing and machine design until 1898, when he became draftsman with the Bureau of Steam Engineering, U.S. Navy Department, and in 1903 was appointed ordnance engineer in the Bureau of Ordnance, Washington, D.C. This latter position he held until his retirement from Government service in 1911.

In addition to his development of the hydraulic variable speed transmission, considered one of the most important artillery inventions of recent times, he did important research work for the Navy Department, on the rifling of guns, constructional details of torpedoes and of submarines, and in the burning of fuel oil. Leaving Washington, he became consulting engineer for the Waterbury Tool Company, Waterbury, Conn., now manufacturer of the hydraulic variable speed transmission in this country, Vickers' Limited of London being the foreign licensee. He also took out numerous patents on forms of gear teeth and on systems of gearing, contributing much to the art of efficient gear transmission and to methods of economical gear production, and devised important improvements in types of ratchet drills and in forms of universal joints.

He had been a member of the A.S.M.E. since 1912, and was also a fellow of the American Association for the Advancement of Science and an honorary member of the Sigma Xi, Tau Beta Pi, and Chi Psi fraternities. He is survived by his widow and a stepson, J. J. Crain.

JOSEPH AUGUSTINE WILSON

Joseph Augustine Wilson died on February 21, 1931, of influenza, at his home in Philadelphia. He is survived by his widow, Helen (Keib) Wilson, whom he married in 1921.

Mr. Wilson was born in New York, N.Y., on July 25, 1899, the son of Charles Paul and Rose (McFadden) Wilson. He spent seven months at the Philadelphia Power Plant Engineering School, and was graduated from Drexel Institute with a B.S. degree in mechanical engineering in 1925. His early experience was secured as draftsman and machinery repair man with J. D. Barcaly & Sons, blueprinting and engineering supply company of Philadelphia, from 1915 to 1917. During the next two years he was with the American Expeditionary Forces, after which he returned to the Barcaly company as foreman of the reproduction department for two years, before entering Drexel Institute.

Following his graduation in 1925, he entered the educational department of the Westinghouse Electric & Manufacturing Co. at East Pittsburgh. After completing the course he was made a traction salesman for the company. Since 1929 he had been in charge of the internal combustion engine sales section at the South Philadelphia Works.

Mr. Wilson served in the Infantry during the World War, was gassed twice and wounded in action. He received the Croix de Guerre for action in the Battle of the Marne. This was not his first military experience, however, as he served on the Mexican Border in 1916 when only sixteen years of age.

Mr. Wilson became a junior member of the A.S.M.E. in 1925.

HENRY G. WOLFE

Henry G. Wolfe, mechanical engineer for the Electric Bond & Share Co., New York, N.Y., died on July 25, 1931, at the White Plains (N.Y.) Hospital, of pneumonia.

Mr. Wolfe was born in Philadelphia, Pa., on August 21, 1872. He was graduated from the mechanic arts course at Drexel Institute in 1895 and from its electrical engineering course two years later. He was machinist for the D'Olier Engineering Company of Philadelphia for six months following his graduation, and draftsman for the Technic Electric Company of that city for the next six months. For a short time in 1898 he served as an oiler in the U. S. Navy. He then became assistant superintendent of the Harrisburg Pipe & Pipe Bending Co., where he remained until the first of June, 1904. Mr. Wolfe went to New York in that year as block engineer for the New York Telephone Company. In 1905 he entered the employ of the New York branch of the Crane Company and two years later became draftsman for the New York Edison Company. He was promoted to the position of assistant chief mechanical draftsman in 1915, engaged in research work at the Edison Laboratories in Orange, N.J., during 1918, and the following year returned to New York to work in the Engineering Department of the New York Edison Company. He resigned in 1920 to become mechanical engineer for the Chile Exploration Company, New York, and after four years with this company accepted a position as assistant mechanical engineer with Thomas E. Murray, Inc. For several years prior to his death, he had devoted himself largely to consulting engineering.

Mr. Wolfe became a member of the A.S.M.E. in 1914. He is survived by his widow, Blanche (Irwin) Wolfe, and by one son, Henry G. Wolf.

ARTHUR JULIUS WOOD

Arthur Julius Wood died on April 18, 1931, a few hours after being struck by a motorcycle in front of his home in State College, Pa. He is survived by his widow, Helen M. (Kerr) Wood, whom he married in 1904, and by one son, Reginald.

Professor Wood was born on September 3, 1874, at Newark, N.J., the son of DeVolson and Frances (Hartson) Wood. His father was a professor of thermodynamics at the University of Michigan and later of mechanical engineering at the Stevens Institute of Technology, and was well known as an engineer, writer, and teacher.

After being graduated from Stevens Institute in 1896 with the degree of mechanical engineer, Professor Wood was associate editor of the *Railroad Gazette* for four years. In 1900 he went to Worcester, where he was instructor in mechanical engineering at the Worcester Polytechnic Institute for two years. During the next two years he was professor of mechanical and electrical engineering at Delaware College, now the University of Delaware, Newark, Del.

Professor Wood became a member of the faculty of The Pennsylvania State College in 1904. For the first four years he was assistant professor of experimental engineering, then associate professor for two years. In 1910 he was made associate professor of railway mechanical engineering, and eight years later professor in that subject. He became head of the department of mechanical engineering in 1922. He formulated the curriculum so that fundamental scientific principles predominated, and built up a staff of instructors devoted to him and working smoothly together.

For three years, 1919–1922, Professor Wood was also in charge of the Thermal Plant of the Engineering Experiment Station, his work dealing with fundamental aspects of heat transfer and their application to various problems of every-day insulation which form such a large portion of many industrial processes and maintenance problems.

Professor Wood was the author of many articles on heat transmission, railway mechanical engineering, and refrigeration. He published one textbook, "Locomotive Operation and Train Control." For some years he was associate editor of *Railroad Mechanical Engineering*.

He was for many years a member of the American Society of Refrigerating Engineers, serving as vice-president, and as president during its twenty-fifth year, 1929. He brought a scientific viewpoint to the discussion of the industrial problems which came before this society which was of particular value because so many of its early members belonged to industrial life.

Professor Wood first joined the A.S.M.E. in 1898, and became a full member in 1907. He was the first chairman, in 1922, of the Central Pennsylvania Section, and had been active in heat-transfer committee work. He was also a member of the American Railway Association (Mechanical Division) and the Society for the Promotion of Engineering Education, a fellow of the American Association for the Advancement of Science, honorary member of Sigma Tau fraternity, and a member of the honorary engineering fraternities, Pi Tau Sigma and Sigma Xi, and of Phi Pi Phi. An M.S. degree was conferred upon him by Penn State in 1916.

WILLIAM PARKER WOOD

William Parker Wood, who died on June 11, 1931, was born at Pueblo, Colo., on March 16, 1905. He attended the Washington, Pa., High School, and was graduated from the University of Pennsylvania in 1926 with a B.S. degree in mechanical engineering. Following his graduation he entered the employ of the Suburban-Counties

Gas & Electric Co., Chester, Pa., as a cadet engineer. He became a junior member of the A.S.M.E. in 1928.

CARL B. WOODWORTH

Carl B. Woodworth, manager of the Railroad Division of the Vanadium Corporation of America, Chicago, Ill., died suddenly at his home on October 24, 1931. He was born at Fort Wayne, Ind., on December 16, 1883, the son of Charles B. and Laura (Case) Woodworth. He attended the public schools there and was graduated in mechanical engineering from Purdue University in 1907. From then until 1916 he served in the Mechanical Engineering Departments of the Wabash and the Baltimore & Ohio Railroads, passing through various grades from machinist to general foreman of the Mt. Clare shops of the Baltimore & Ohio. He then entered the employ of the American Arch Company with whom he remained until 1918, when he was commissioned Captain of Engineers, U.S. Army. He served fifteen months with the A.E.F. on railroad work in France.

Upon his return to this country Mr. Woodworth joined the Foreign Sales Department of the American Locomotive Company and spent six years in the Argentine and Brazil, engaged in sales and service work. During the last three years, he was assistant South American manager for the company. He also handled the business of the American Car and Foundry Company in Brazil. In 1926 he was identified with the Premier Staybolt Company as special technical representative throughout the United States, from which position he joined the Vanadium Corporation of America in May, 1927, as manager of its Western Division. In August, 1930, Mr. Woodworth was made manager of the Railroad Division of the Vanadium Corporation.

Mr. Woodworth was elected an associate member of the A.S.M.E. in 1917 and was promoted to full membership in 1929. He is survived by his widow, Margaret (Moore) Woodworth, whom he married in 1927, and by a daughter, Janette.

BEVERLY LYON WORDEN

Beverly Lyon Worden, president of the Cutler-Hammer Manufacturing Company of New York and Milwaukee, died on March 28, 1931, at his home in West Orange, N.J., after an illness of several months.

Mr. Worden was born in Chicago, Ill., on February 8, 1871, the son of Albert Lyon and Anne (Robson) Worden. He received his B.S. in civil engineering from the University of Wisconsin in 1893, and for several years following graduation was employed by the Wisconsin Bridge & Iron Corp., of North Milwaukee, Wis., spending some time in the shops and drafting room and later serving as chief draftsman and construction engineer. In December, 1901, he left this company to form the Worden-Allen Company, engineers and contractors for fireproof construction. He designed, constructed, and operated its structural steel plant in Milwaukee, and served as president of the company for twenty years.

In 1910 he founded the Lackawanna Bridge Company, and designed, built, and operated its plant at Buffalo, N.Y., continuing to give about half his time to the Worden-Allen Company. He remained president of the Lackawanna Bridge Company until it was taken over by the Bethlehem Steel Corporation in 1924. In 1917 he also assumed charge of the design of the Newark Bay (New Jersey) Shipyard, for the Submarine Boat Corporation, and was general manager of the shipyard during the World War. He introduced the fabricated principle into shipbuilding, and constructed a large number of cargo ships on that principle for the Emergency Fleet Corporation, the parts being manufactured in shops located at different points and shipped to Newark for assembly. In 1918 he bought the Ferguson Steel & Iron Corp., at Buffalo, a company then engaged in the fabrication of steel for barges and buildings and also operating a shipyard. Under his supervision six seagoing tugs for the United States Navy were completed during the World War, after which the shipyard was closed. The fabricating shop was kept in operation for about five years.

Early in 1923 Mr. Worden became identified with the Cutler-Hammer Manufacturing Company as its vice-president and director, succeeding A. W. Berresford as president the following year. He was also interested for a time in the Beaver Board Company, which he served as president and chairman of the board, and was a director of the Buffalo Sand & Gravel Corp.

Mr. Worden became a member of the A.S.M.E. in 1921. He also belonged to the American Institute of Mining and Metallurgical Engineers, the American Institute of Electrical Engineers, the Western Society of Engineers, the National Electrical Manufacturer's Association, the Masonic fraternity, and a number of clubs in Chicago, Milwaukee, Buffalo, and New York.

Besides his widow, the former Katherine Elizabeth Taylor of Milwaukee, whom he married in 1901, he is survived by two married daughters, Mrs. Willis S. Brace and Mrs. William S. Valentine, of East Orange, N.J.

BARZILLAI GARDNER WORTH

Barzillai Gardner Worth, vice-president and chief engineer in charge of power plant design and development of Walter Kidde & Company, Inc., New York, since 1916, died at the Fifth Avenue Hospital in that city on May 25, 1931, following an operation for appendicitis. Surviving him are his widow, Mabel D. (Palmer) Worth, whom he married in 1899, and one son, Barzillai G. Worth, Jr.

Mr. Worth was a fellow of the American Institute of Electrical Engineers and had been a member of the A.S.M.E. since 1917. He also belonged to the American Electrochemical Society, New York Electrical Society, and American Chemical Society.

Mr. Worth had made his home in West Orange, N.J., for some years. He was born at Tenafly, N.J., on June 5, 1880, the son of Archibald C. and Elizabeth H. (Anderson) Worth. He was graduated from the Stevens Institute of Technology in 1901 and immediately entered the employ of Walter Kidde, who has supplied the following statement regarding his work.

"Mr. Worth was essentially an engineer who thoroughly enjoyed his work. He looked upon every new problem as a grand adventure, as an opportunity to offer a solution that would be a step in advance of anything that had been done before. As a result, his whole engineering career was studded with unusual accomplishments in his chosen field of industrial and power plant building. While it cannot be said that he was an inventor in the sense that he evolved fundamental ideas in mechanics, it is true that he had a mind that constantly sought to do old things in new ways by applying what was already accepted in one branch of engineering to uneconomical methods or processes used in another branch.

"One of his first successes was the development of, as far as we can learn, the first push-button elevator. This elevator was built under his specifications by the Otis Elevator Company back in 1905 for John Nehl & Company in Jersey City. You can imagine the difficulty of building this complicated mechanism in those days when the electrical industry was so little prepared in the matter of electro-mechanical devices. This elevator has been in operation up to within the last two or three years.

"As early as 1907 Mr. Worth equipped the plant of the American Hard Rubber Company with alternating-current synchronous motors for the correction of low power factor. This was the first rubber plant and among the first industrial plants to be driven with synchronous motors. In addition to this, some of these motors were laid out as direct drivers for the rubber mills and calendars, something unheard of at that time. Shortly after this he also adapted from central-station practice the use of the push-button remote-control switchboard, another long step forward in industrial plant power applications.

"The spray pond for cooling condenser water built by him at the plant of the Hyatt Roller Bearing Company at Harrison, N.J., adjacent to the main line of the Pennsylvania Railroad Company in 1913, was said to be one of the first in the country. Certainly it was a great novelty to the passengers of the Pennsylvania Railroad, but to the Hyatt Roller Bearing Company it represented a saving of $25,000 per year.

"Mr. Worth's tremendous energies took him into the field of electrochemistry, where he designed a battery of what was then revolutionary electrochemical cells for the manufacture of chlorate of potash, which during our participation in the World War supplied a large part of this chemical for the manufacture of primers or cartridges.

"Something of his sheer versatility may be gleaned from the fact that in the early post-war period he developed a high-carbon electric-furnace tool steel which was far in advance of anything in the market at the time. This experience with the use of electric furnaces so fired his fertile imagination that he set about designing a new principle in the design of electric furnaces in which a creditable start was made before he died.

"All these things and many more were sandwiched between his main work of power-plant design and equipment installations for industrial plants. No matter what job he tackled he brushed aside the obvious solution until he was convinced that his was the most economical way that his lively imagination could devise. As an illustration of this he developed a scheme which revolutionized the method of liming skins in the leather industry when we built the new plant up-state New York. The ancient and accepted method in this stage of tanning leather was to soak the raw skins in lime vats set at floor level. At frequent intervals the skins in each vat were agitated by turning them about with long poles in the hands of skilled and high-priced labor. Mr. Worth set to work to plan a more economical scheme and devised

a system of mechanically operated wooden drums which, at the required intervals, revolved a certain number of times. This new method of agitation reduced the force from fifty men to two men in this one department. The saving in cost of labor in ten years time will go far toward paying for the cost of the entire new plant."

AMBROSE EVERETT YOHN

Ambrose Everett Yohn, general manager for the Huntingdon & Broad Top Mountain Railroad & Coal Co., died on October 7, 1931. He is survived by his widow, Mrs. Edna Rhodes Yohn, of Huntingdon, Pa., whom he married in 1911.

Mr. Yohn was born at Reading, Pa., on October 5, 1870, the son of Charles Rutter and Hannah Rebecca Yohn. He attended the Bethlehem Preparatory School and was graduated from Lehigh University with a mechanical engineering degree in 1897.

In 1918 and 1919, Mr. Yohn was general foreman for the Juniata Division of the Pennsylvania Railroad, and the following year general manager of the coal mines and plant of the Kenrock Coal Company. With the exception of those two years, he was connected, from the time of his graduation until his death, with the Huntingdon & Broad Top Mountain Railroad & Coal Co., being advanced from the position of assistant master mechanic to that of general manager.

Mr. Yohn became a member of the A.S.M.E. in 1897.
